But little notice seems to have been bestowed on this diagnostic sign of late years, and, in fact it had fallen into almost total discredit, when Dr. Montgomery, of Dublin, took it up, and by his excellent description of its characteristic appearance, brought it into much higher estimation than it has ever before enjoyed. I shall read for you some part of his observations on the subject; they are taken from his very able and elaborate article in the *Cyclopædia of Practical Medicine*, on the "Signs of Pregnancy." After remarking that this is one of the changes consequent on pregnancy which is of the "utmost value" in evidence of the fact, and having noticed Roederer's account of the areola, he proceeds:—"One other we shall add, as equally constant, which is a soft and moist state of the integument, which, together with its altered colour, gives us the idea of a part in which there is going forward a greater degree of vital action than is in operation around it; and we not unfrequently find that the little glandular follicles are bedewed with a secretion sufficient to damp and colour the woman's inner dress. We must recollect, also, that these changes do not take place immediately after conception, but occur in different persons after uncertain intervals; we must therefore consider, in the first place, the period of pregnancy at which we may expect to gain any useful information from the condition of the areola."

"We cannot speak very positively as to what may be the earliest period at which this change can be observed, but we have certainly been satisfied of its existence at the end of the second month; at which period the change of colour is by no means the most distinct character to be observed; but the turgescence of the nipple, and the development of the little glandular follicles, are the objects which should principally engage our attention,—the colour at this period being, in general, little more than a deeper shade of rose or flesh colour, slightly tinged with a yellowish or brownish hue. During the progress of the next two months, the changes in the areola are, in general, perfected, or nearly so; and it then presents the following character:—A circle around the nipple, whose colour varies in intensity according to the peculiar complexion of the individual, being generally much darker in persons with black hair, dark eyes, and sallow skins, than in those of fair hair, light-coloured eyes, and delicate complexions. The extent of the circle varies from a diameter of

an inch to an inch and a half, and increases in some as pregnancy advances, as does also the depth of colour. In the centre of this circle the nipple is observed partaking of the altered colour of the part, and appearing turgid and prominent; and the part of the areola more immediately around the base of the nipple has its surface rendered unequal by the prominence of the glandular follicles, which, varying in number from twelve to twenty, project from the sixteenth to the eighth of an inch; and, lastly, the integument covering the part is observed to be softer and more moist than that which surrounds it; and the breasts themselves are, at the same time, observed to be full and firm, at least more so than was natural to the person previously. Such," adds Dr. Montgomery, "such we believe to be the essential character of the true areola, the result of pregnancy; and that when found possessing these distinctive marks, it ought to be looked on as the result of that condition alone, no other cause being capable of producing it."

Placing the fullest reliance on the accuracy of this description, I should recommend to you the importance of comparing it with actual examples, as they may happen to fall in your way. In order to judge satisfactorily from appearances like these, it were advisable to combine your own experience with the observations of others; and I need scarcely add, that no pains can be superfluous when bestowed for the purpose of putting us in possession of so capital a sign. Only conceive the importance of our being able to obtain evidence of a highly probable, if not a conclusive, character, from simply viewing the female mamma! I dare not, from any experience of my own, venture to assert that so high an amount of evidence can be procured from even the most careful inspection: but the authority of Dr. Montgomery, Dr. Hamilton of Edinburgh, and others who have recently devoted their attention to this subject, is sufficient to warrant me in pointing out to you the change of appearance in the areola as a sign of pregnancy worthy of your most especial notice.

Discoloration of the vagina.—As somewhat related to the alteration of colour just noticed, I may here introduce a few words respecting a curious diagnostic sign of pregnancy lately announced in Parent-Duchatelet's volumes. It appears that the extensive opportunities which M. Jacquemin has had, in examining the public women at the Dispensary in Paris, have enabled that gentleman to discover a peculiarity belonging to the pregnant state—namely, a change of colour in the lining membrane of the vagina. It becomes of a

violet hue, or purplish, like the lees of wine. M. Jacquemin says he is never deceived in this appearance, and that he can depend upon it even without taking into account any of the other symptoms commonly observed. He has had, it seems, no less than 4,500 cases passing through his hands, and upon which he was enabled to prove the correctness of his diagnosis.

Should this be found eventually a good test of pregnancy, it will be of great importance in forensic medicine. In ordinary practice there would be strong objections to the employment of it,—while every facility would be afforded for observing the areola: but in medico-legal practice the awkwardness of applying the *speculum vaginæ* would, perhaps, be readily overlooked.

5. *Motions of the fœtus.*—The remaining signs are of what has been called a *sensible* nature, perceptible by the touch or hearing: they are derived more immediately from the presence of the fœtus, and are to be appreciated when the child is alive and healthy. We may perceive the movement of the fœtus by having recourse to a little management. Towards the conclusion of the fifth month, or even somewhat earlier (for some *quicken*, as it is called, that is, feel the first symptoms of the vitality of a being within them, earlier than others), the organs of locomotion in the fœtus are in such a state of activity as to become sensible to the hand applied on the exterior of the abdomen, and are even sometimes distinctly visible through the clothes of the female. It must, however, be recollected, that in some women, spasmodic contractions of the uterus and of the intestines may present very similar phenomena; and even experienced accoucheurs are said to have been deceived by relying upon this sign. What Dr. Gooch says on the subject—and he attaches very high importance to it—deserves to be quoted:—"If the hand is laid on the naked abdomen, between the pubes and the umbilicus, the fœtus will sometimes be felt to stir. As, however, it moves only occasionally, this may not happen during the examination. It is said that by dipping the hand in cold water, and laying it suddenly on the naked abdomen, the fœtus may be made to move. As I have long had the cold hand of a dyspeptic sufferer, I have no occasion to dip my hand in cold water; it is always cold enough to make the patient shrink, and by laying it suddenly on the naked abdomen, I have sometimes felt the child move, but this has been only an occasional occurrence. If distinctly felt, it is of course the most conclusive symptom."

Quickening.—Connected in some measure with this subject is the question of the

fact of quickening. The phenomenon of quickening was supposed by the older physiologists to arise from the accession of life (as the term implies) to the fœtus at that period. But when we know that what is understood in general by *quickening* does not take place till between the fourth or fifth month after conception, we are prepared to reject that hypothesis, for we know that the communication of life is the immediate consequence, if not the very essence, of the act of conception.

It is more probable that *quickening*, so called, is the first impression made by the fœtus on the mother, the fœtus being then sufficiently developed, and sufficiently lively, to make a sensible impression on the mother by its movement.

Another hypothesis, of more recent date than the foregoing, is, that it arises from the sudden ascent of the uterus out of the pelvis, that viscus now requiring more room for its development.

But whatever be the true cause, the sensation to the mother is decisive. She generally compares it to something tapping within the uterus, or to the fluttering of a bird; and syncope often accompanies the first impression.

The time of quickening is not the same in different women, for it depends, 1st, on the acuteness of the mother's sensations; 2dly, on the strength of the fœtus; and 3dly, on the quantity of the liquor amnii present.

These remarks are not to be considered as made on a point merely curious: for the medical jurist may be particularly examined as to the fact of quickening, whether it has taken place or not: the crime of wilful abortion, for example, is either a capital felony, or one of a lower degree of guilt, according as the fact of quickening may have been ascertained or not. But the medical witness has no other means of solving the question, than by ascertaining the movement of the fœtus.

6. *State of the cervix uteri.*—The next sign to which I would direct your attention, is that which must be ascertained by the touch—*le toucher* of the French accoucheurs. In the unimpregnated state, it will be remembered that the cervix uteri forms a nipple-like prominence, which projects into the vagina about two-thirds of an inch. Shortly before delivery, it is found almost wholly obliterated, or nearly flat, to the finger. Now the obliteration is effected gradually, during the state of pregnancy, but a change does not begin to be perceived until about the fifth month. By the seventh, it has become much altered, very soft, broad, and short, and so on to the close of gestation. In making the examination requisite for ascertaining the state of the part, and thus judging of the stage of

pregnancy, the forefinger of the right hand is to be applied against the projection in the vagina, while the left hand is to be laid on the abdomen. By then pressing gently with the left hand downward, the finger in the vagina has full liberty to explore the shape and size of the cervix, at the same time that another observation may be made. By alternately forcing upward with the right forefinger, and downward with the left hand, we may assure ourselves that the tumor felt through the walls of the abdomen is the same as that felt through the vagina—the most satisfactory proof that it is an enlarged uterus. This method may be practised with effect as early as the fourth or fifth month: but it should be added, that the examination as to the form of the cervix cannot in general be successfully made until about the sixth. Both this examination and the former, relative to the movement of the foetus, may be perhaps best effected, the female being recumbent. Dr. Gooch says, “the bladder should be empty, the woman in bed, in her night-dress, on her back, in a posture between sitting and lying, with the knees slightly drawn up.”

Ballottement.—Another important point to be ascertained by the touch is the *ballottement*. It will be recollected that in the pregnant uterus the foetus floats in the liquor amnii, and when the female who is to be examined is in the erect posture, the head of the foetus, if there be one present, must rest over the top of the vagina. “Now, if the examiner,” says Dr. Gooch, “applies his finger to the uterus, just in front of the neck, and gives it a push, the foetus will float for an instant, and the next instant fall with perceptible weight on the point of the finger; this sensation, if once felt, can never be mistaken; it is scarcely inferior in conclusiveness to the muscular movements of the child, and has this advantage over the latter, that it can be felt, whether the foetus is alive or dead.” The best time for detecting this rebound, or *ballottement*, as the French call it, is from the fifth to the seventh month: the reason is obvious, when we consider the relative proportion of the liquor amnii to the bulk of the foetus; “earlier than the fifth month the foetus is too light to be felt; and later, it is often too closely packed to be moved.”

7. *Auscultatory signs.*—I have reserved for the last, an account of the latest and best, method of ascertaining the existence of pregnancy—a method which, when successfully employed, not only assures us of the presence of the foetus, but of its vitality. It is not applicable where the child is dead, or peculiarly placed in the uterus. But with these exceptions, the use of auscultation is at-

tended with advantages to the medical jurist which cannot be too highly prized.

We are indebted to M. Kergaradec for the first hint of applying auscultation, with the naked ear, or the stethoscope, to the abdomen of the pregnant female. M. Mayor, of Geneva, preceded him, indeed, by a few years, in observing the pulsations of the foetal heart through the abdominal parietes; but not having made any practical application of the fact, he has scarcely any claim as a discoverer. Through the stethoscope, M. Kergaradec detected two distinct systems of pulsation in the abdomen of the pregnant female—the one belonging to the foetal heart, the other to the placenta. Let us suppose the woman five or six months gone with child: on applying the stethoscope or the naked ear to the middle space between the umbilicus and the crural arch on the left side, we shall probably hear a ticking sound like that of a watch; this is the beating of the foetal heart, and the pulsations, which are double, are generally from about 120 to 160 in the minute, while perhaps the mother's pulse, reckoned by holding the wrist at the same time, does not exceed 70.

I may mention here, in passing, that there appears some contrariety in the statements of different observers respecting the rate of the foetal pulse. Dr. Jeffray, of Glasgow, Dr. Hamilton, of Edinburgh, and others, maintain that the pulsation in the umbilical cord, and, of course, that of the foetal heart, does not exceed sixty in the minute—nay, is rather less. So many able auscultators, besides Kergaradec, have satisfied themselves that the foetal pulsation is at least double as quick as the Scotch professors allow it to be, that one cannot help suspecting that there is some mistake, and that probably both parties are really not so much at variance, after all. Dr. Hamilton, and those who are with him, allude particularly to the beating of the cord, and that about the period of labour; when, in fact, the first stage is over; or any stage, as it would seem, previous to respiration. The others trust to their ears, while yet there may be no symptom of labour commencing. Now may there not be an essential difference in the circumstances?—may not some change, hitherto not well observed, have taken place in the foetal circulation, preparatory to the commencement of the respiratory process?—may not some new arrangement have occurred, the effect of which is to reduce the circulation of the foetus in the number of beats? I feel so satisfied of the trustworthiness of both sets of observers, that I can only endeavour to reconcile them by thus imagining that each has been describing a different state of things. But to return to the phenomena.

Having observed the double pulsations, the stethoscope is next to be applied to another part of the abdomen; and here we shall probably find the beating of the other system, *single* pulsations, perfectly isochronous with the pulse of the mother. These are, moreover, attended with a peculiarity which distinguishes them from the beats of a common artery; they are characterized by a bellows-sound, or *bruit-de-soufflet*. This phenomenon, which is observed to be connected with the *placental* circulation, is said to be appreciable much earlier during gestation than the double beating already described: it may be perceived, according to some, even as early as the end of the *third* month, upon applying the stethoscope just above the pubes. But it is more probable that in general it cannot be detected till the fourth month.

It sometimes requires considerable patience before we can place the stethoscope so as to be able to hear what we are in quest of: the state of the woman's intestines, which may be distended with flatus, may deceive us; the position of the placenta in the uterus, its various attachments, sometimes even over the os tinæ, and the various positions of the foetus itself, are all calculated occasionally to try our ingenuity as well as our good temper.

Conclusions respecting auscultation.—Three conclusions may be borne in mind, with respect to the use of the stethoscope, in attempting to ascertain pregnancy:—

(a.) That though we may be unable, after repeated trials, to hear *any* sound with the instrument applied to the abdomen, we are not to infer that pregnancy does not exist; for the foetus may be dead, or very feeble, or so situated that we cannot hear either the beating of its heart or the circulation in the placenta.

(b.) That where we can hear nothing more than the placental pulsation, we are not justified in asserting that pregnancy exists; for perhaps the uterus may contain some other substance than a foetus, or there may probably be some peculiar condition of the uterine vessels.

(c.) But that whenever we distinctly hear the double pulsations, with or without the placental souffle, we may affirm positively that the woman is pregnant. Nay, should we detect simultaneously another set of double pulsations, as sometimes happens, we may announce the fact of twin pregnancy.

Nor are these all the advantages to be derived from the use of the stethoscope in connexion with medico-legal inquiries. The auscultatory method will further inform us whether the pregnancy be extra-uterine or not: also, by its indications respecting the placenta, where may be the

safest place of the abdomen on which to perform the Cæsarean section.

It would, I think, be superfluous to say more on the great importance of auscultation as a diagnostic aid to the medical jurist in determining the pregnant state; but I cannot refrain from suggesting one short piece of advice in conclusion, and that is, that you should avail yourselves of every opportunity of acquiring dexterity in this application of the stethoscope,—for it is by diligent practice alone that you can attain that degree of tact which will give satisfaction to yourselves, as well as to those who may require your opinion.

LECTURES

ON

MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

By JON. PEREIRA, Esq., F.L.S.

LECTURE LIII.

GENTLEMEN,—In this lecture I propose to examine those pharmacological agents yielded us by the order

APOCYNACEÆ.

The first and most important substance in this family is the *Nux vomica*.

Strychnos Nux vomica.

History.—We became acquainted with *Nux vomica* through the Arabian authors. In the Latin translation of one of the works of Serapion (who is supposed to have lived early in the eleventh century), we find the word *nux vomica*, but it appears to have been applied to some other substance (probably to St. Ignatius's bean). "Est nux," says he, "cujus color est inter glaucedinem et albedinem, major avellana parum et sunt in ea nodi." To which he afterwards adds, "mouet vomitum;" from which I presume the name of *vomic*, or *vomiting nut*, was originally derived. It is probable that the *nux mechil* of Serapion is the substance which we denominate *nux vomica*.

Botanical history.—The following is a short abstract of the characters of this plant, taken from Roxburgh's "*Flora Indica*," to which I must refer for further information:—

The *Nux vomica* tree is of middling size, and is common in almost every part of the coast of Coromandel; flowering during the cold season. It belongs to class

Pentandria, order *Monogynia*, of the Linnean classification. The trunk is short, often crooked, and pretty thick; the branches irregular; the wood white, hard, and bitter. The leaves are opposite, oval, shining, entire, and from three to five nerved.

FIG. 142.—*Strychnos Nux vomica*.

The flowers are in small terminal corymba, and are composed of a five-toothed calyx, a funnel-shaped, greenish white corolla, five stamina inserted over the bottom of the divisions of the corolla, a two-celled ovarium, a style the length of the tube of the corolla, and a capitate stigma.

The fruit is a round smooth berry, of the size of a pretty large apple, covered with a smooth, somewhat hard, shell, of a rich beautiful orange-colour when ripe; filled with a white, soft, gelatinous pulp, which is greedily eaten by many sorts of birds, and, therefore, seems perfectly innocent.

The seeds (*nuxes vomicae*) are several, immersed in the pulp of the berry and attached to a central placenta. As they occur in commerce they are round, peltate, scarcely an inch in diameter, nearly flat, or very slightly convex on one side, and concave on the other, and are surrounded by a filiform, annular stria. From their fancied resemblance to grey eyes, as well as from their being poisonous to crows, the Germans term them *Krähenaugen*, or *crows'-eyes*. In the centre of the ventral surface of the seed is the orbicular hilum or umbilicus.

FIG. 143.—*Nux vomica*.

a, The convex surface.
b, The concave surface.

These seeds have two coats; the outer one, or *testa*, is simple, fibrous, and gives origin to short silky hairs, of an ash-grey or yellowish colour, and which are directed from the centre towards the circumference: within this is the inner coat, or *endopleura*, which is simple, and very thin, and envelops the nucleus of the seed.

FIG. 144.—Seed coats of *Nux vomica*.

a, Testa, with the hairs attached to it.
b, Endopleura.
c, Albumen.

This nucleus is composed of two parts—namely, albumen and embryo. The albumen is bipartite, cartilaginous or horny, of a dirty white colour, of an intensely bitter taste, and has in its interior a cavity (*loculamentum verum*). Unlike that of most seeds, the albumen nux of vomica is of a poisonous nature. The embryo, which is milk-white, is seated in the circumference of the seed, its locality being frequently indicated by a point somewhat more projecting than the surrounding parts. It consists of two large cordiform, acuminate, triple-ribbed, very thin cotyledons, a distinct cauliculus, and a centripetal radicle (*i. e.* a radicle directed towards the centre of the fruit).

FIG. 145.—Sections of *Nux vomica*.

c, Transverse section of the seed.
d, The cavity laid open to show the natural situation and figure of the embryo.

Chemical composition.—Several analyses of this seed have been published: but I shall pass over those made by Desportes, Bracconot, and Chevreul, and principally confine myself to that of Pelletier and Caventou, made in 1818. These celebrated chemists found the following substances:—

1. Strychnic or Igasuric acid.
2. Strychnia } in combination with
3. Brucia } strychnic acid.
4. A little wax.
5. A concrete oil.
6. A yellow colouring matter.
7. Gum (a considerable quantity).

8. Starch (a little).

9. Bassorine.

11. Vegetable fibre.

12. In the ashes were found carbonate of lime and chloruret of potassium.

The *strychnic* or *igasuric acid*, mentioned in this analysis, in many of its properties agrees with malic acid, but is distinguished by the solubility of its alkaline salts in alcohol, and by its action on the salts of copper. Thus, when a solution of the ammoniacal sulphate of copper is added to the infusion of *nux vomica*, the liquid immediately becomes of an emerald green colour, and gradually deposits a greenish-white precipitate of the strychnate of copper; the ammoniacal sulphate of strychnia remaining in solution. In this action on the cupreous salts, strychnic agrees with meconic acid; from which we distinguish it by the red colour which meconic acid produces when added to the persalts of iron, and which is not developed by strychnic acid.

If nitric acid be mixed with the infusion or decoction of *nux vomica*, an orange-red colour is produced, by the action of the acid on the brucia and yellow colouring matter. A solution of iodine at first communicates a yellowish-brown tint to the decoction, but after a few minutes the colour disappears, the iodine being converted into hydriodate (and probably into iodate also) of strychnia and brucia, and is then no longer detectable by starch, unless nitric acid or chlorine be also added. The salts of iron communicate an emerald green colour to the infusion of *nux vomica*, which disappears on the addition of hydrochloric acid: this coloration does not depend, according to Pelletier and Caventou, on the strychnic acid; nor can it arise from tannic acid, since gelatine gives no indication of the presence of this acid. By boiling infusion of *nux vomica* with animal charcoal, it is deprived of this power of becoming green on the addition of ferruginous salts. Tannic acid, or infusion of galls, produces a copious precipitate with the infusion or decoction of *nux vomica*; but by heating the liquid the precipitate is dissolved. This precipitate consists of tannic acid, strychnia, brucia, and some other vegetable matter. Alcohol added to the infusion of *nux vomica* precipitates the gum. Acetate and subacetate of lead produce copious precipitates, composed of oxide of lead combined with strychnic acid, gum, and some fatty and colouring matter.

The wax mentioned in the above analysis seems to be derived from the hairs covering the seeds: it enables them to resist moisture. Some authors mention resin as a constituent of these seeds: its existence is very probable, since an alcoholic

tincture of *nux vomica* becomes milky when mixed with water. By distillation with water, an odorous, non-acid, innocuous principle is procured. As the decoction of *nux vomica* undergoes the vinous fermentation, the presence of sugar has been presumed. Meissner says he found copper in the ashes of *nux vomica*, but I have never been able to detect it.

Physiological effects: 1. *On vegetables.*—Marcet states, that a quarter of an hour after immersing the root of a haricot plant (*Phaseolus vulgaris*) in a solution of five grains of the extract of *nux vomica* in an ounce of water, the petals became curved downwards, and in twelve hours the plant died. Fifteen grains of the same extract were inserted in the stem of a lilac tree, on the 15th of July, and the wound closed. In thirteen days the neighbouring leaves began to wither.

2. *On animals generally.*—*Nux vomica* appears to be poisonous, in a greater or less degree, to all classes of animals. On the vertebrata its effects are very uniform, though larger quantities are required to kill herbivorous than carnivorous animals. Thus a few grains will kill a dog, but some ounces are required to destroy a horse. It occasions in all, tetanic convulsions, increased sensibility to external impressions, asphyxia, and death.

3. *On man.*—We shall establish three degrees of the operation of *nux vomica* on man.

(a.) *First degree: tonic and diuretic effects.*—In very small and repeated doses, *nux vomica* usually promotes the appetite, assists the digestive process, increases the secretion of urine, and renders the excretion of this fluid more frequent. In some cases it acts slightly on the bowels, and occasionally produces a sudorific effect. The pulse is usually unaffected. In somewhat larger doses, the stomach not unfrequently becomes disordered, and the appetite impaired.

(b.) *Second degree: rigidity and convulsive contraction of the muscles.*—In larger doses, the effects of *nux vomica* manifest themselves by a disordered state of the muscular system. A feeling of weight and weakness in the limbs, and increased sensibility to external impressions, (of light, sound, touch, and variations of temperature), with depression of spirits and anxiety, are usually the precursory symptoms. The limbs tremble, and a slight rigidity or stiffness is experienced when an attempt is made to put the muscles into action. The patient experiences a difficulty in keeping the erect posture, and, in walking, frequently staggers. If, when this effect is beginning to be observed, you tap him suddenly in the ham while standing, you may frequently bring on a slight

sive paroxysm, so that he will have difficulty to prevent himself from . I have often in this way been recognize the effect of nux vomica muscular system, before the patient experienced any particular symptoms. The use of the medicine be still permitted in, these effects increase in intensity and the voluntary muscles are thrown into convulsed state by very slight causes. When the patient inspires more than usual, or attempts to walk, or to turn in bed, a convulsive paroxysm is brought on. The sudden contact of external bodies also acts like an electric shock on him. The further emetic effect of nux vomica increases the severity of the symptoms; the paroxysms occur without the agency of any exciting cause, and affect him when lying perfectly quiet and still in the muscular fibres of the pharynx, oesophagus, and bladder, also affected, and Trousseau says those of the penis are likewise influenced, and nocturnal and diurnal erections become inconvenient even in those who, for some time before, had lost somewhat of virility. Females also, he says, experience more energetic venereal desires; "we have," he adds, with great confidence, "received confidential information on this point, which cannot be doubted." The pulse does not appear to be uniformly affected; for the most part it is increased in frequency between convulsive attacks, but Trousseau says he found it calm even when the dose of medicine was sufficient to cause muscular rigidity. Previous to the induction of the affection of the system, various painful sensations are sometimes experienced in the skin, which have been compared to the creeping of serpents (formication), or to the passage of electric shock; and occasionally an eruption makes its appearance.

It is remarkable that in paralysis, the effects of nux vomica are principally observed in the paralysed parts. The formication and the convulsions here first attack themselves; and Magendie states he observed sweating confined to these parts. "I have seen," says this physiologist, "the affected side covered with an eruption, while the opposite side was free from it. One side of the face is sometimes sensible of a very bitter taste, which is not perceptible to the other side."

Third degree: Tetanus and Asphyxia.— I cannot do better than relate the case of poisoning by nux vomica reported by Ollier, in order to illustrate the most violent degree of operation of this drug. A young woman swallowed

between three and four drachms of this substance in powder, and in half an hour was seen by Mr. Ollier. She was sitting by the fire, quite collected and tranquil; her pulse about 80, and regular. He left her for about ten minutes to procure an emetic, and on his return found that she had thrown herself back in her chair, and that her legs were extended, and considerably separated. She was perfectly sensible, and without pain, but seemed in alarm, laid hold of her husband's coat, and entreated him not to leave her. A perspiration had broken out on her skin, her pulse had become faint, and much quicker, and she called frequently for drink. She then had a slight and transient convulsion. Recovering from it, she was in great trepidation, kept fast her hold of her husband, and refused to let him go, even for the alleged purpose of getting her drink. In a few minutes after, she had another, and a more violent attack, and shortly afterwards, a third: the duration of these was from a minute and a half to two minutes. In them she retained her grasp; her whole body was straightened and stiffened, the legs pushed out and forced apart. I could not, says Mr. Ollier, perceive either pulse or respiration; the face and hands were livid, the muscles of the former, especially of the lips, violently agitated, and she made constantly a moaning, chattering noise. She was not unlike one in an epileptic fit, but did not struggle, though, as she was forced straight out, it became difficult to keep her from falling on the floor.

In the short interval of these attacks she was quite sensible; was tormented with incessant thirst; perspired; had a very quick and faint pulse; complained of being sick, and made many attempts to vomit. (I should state she had swallowed some ipecacuhana powder to evacuate the poison). She continued to refuse to let her husband move, and to the question whether she was in pain, replied, no—no—no!

A fourth and most vehement attack soon followed, in which the whole body was extended to the utmost, and she was rigidly stiff from head to foot, insomuch that, with all the force of the surgeon, he could not bend her thighs on the pelvis to replace her in her seat. From this she never recovered; she fell into a state of asphyxia, and never breathed again. She now relaxed her grasp; her discoloured hands dropped upon her knees; her face, too, was livid; the brows contracted; the lips wide apart, shewing the whole of the closed teeth, and a salivary foam issued plentifully from the corners of her mouth. The expression of the whole countenance was at this moment very

frightful. On removal of the body, it was discovered that the urine had been discharged. She died in about an hour after taking the poison. Five hours afterwards she was still as straight and stiff as a statue; if you lifted one of her hands, the whole body moved with it, but the face had become pale in comparison, and its expression more placid.

Post-mortem appearances.—In the case just related, the body was observed to be rigid after death, but in animals the reverse is generally noticed. As in other cases where death takes place from obstructed respiration, venous congestion is observed. Occasionally there is redness or inflammation of the alimentary canal, and now and then softening of the brain or spinal cord.

Modus operandi.—There are several points connected with the modus operandi of nux vomica, which require examination.

In the first place, is this seed a local irritant?—In medicinal doses it does not usually disorder the stomach, nor is it invariably irritant in its operation, even when swallowed as a poison. In some instances, however, the pain and heat in the stomach, the burning in the gullet, and the nausea and vomiting, are evidences of its local action; and in several cases marks of inflammation have been observed in the stomach on examination of the body after death.

Secondly, on what part of the body does nux vomica exercise a specific effect?—The symptoms clearly indicate the nervous system to be specifically affected. But what portion of it—the cerebro-spinal or the ganglionic system? As the voluntary muscles are supplied with nervous influence from the cerebro-spinal portion of the nervous system, it is presumed that it is on this portion that nux vomica exerts its principal or sole influence. Physiologists, however, have endeavoured to ascertain what part of the cerebro-spinal system was principally affected. Now the tetanic symptoms, and the absence of narcotism, have led to the conclusion that the spinal cord was the seat of the disease—a conclusion supported by the fact that the division of this cord—nay, even complete decollation, will not prevent the poisonous effects of nux vomica, whereas the destruction of the cord by the introduction of a piece of whalebone into the spinal canal causes the immediate cessation of the convulsions; and if only part of the cord be destroyed, the convulsions cease in that part of the body only which is supplied with nerves from the portion of medulla destroyed. These facts, then, originally observed by Magendie, and which I have myself verified, lead to the conclusion that the abnormal influence, whatever it may be, which causes the convulsions to take

place, is not derived from the contents of the cranium, but from the medulla spinalis itself. Moreover, as the motor nerves seem principally affected, it has been presumed that the disorder is seated in the anterior columns of the cord. But the increased susceptibility to the influence of external agents clearly proves that the sensitive nerves, and, therefore, the posterior columns of the cord, are also in an abnormal state.

M. Flourens, a distinguished French physiologist, asserted that the part of the nervous system on which nux vomica more particularly acted, was the medulla oblongata. But MM. Orfila, Ollivier, and Drogartz, in their report on a case of poisoning by this substance, particularly mention that they observed no traces of alteration in the condition of the medulla oblongata, the tuber annulare, or the crura cerebri, which is in opposition to Flourens' opinion, for he asserted that the specific or exclusive action of each substance on each organ always left after death traces of its action, sufficient to distinguish the affected from other organs.

But it may be asked, is the cerebrum unaffected by nux vomica? I think we are hardly justified in replying to this in the affirmative. It is, indeed, true that the intellectual functions are not usually much disordered by this drug, but the mental anxiety commonly experienced by persons under its use, the occasional appearance of stupor, and the observations of Andral and Lallemand on the injurious effects of it in some apoplexies, leave no doubt that occasionally at least the cerebrum is affected.

The cerebellum is said by some to be acted on by nux vomica, but for the most part on hypothetical grounds, though it must be mentioned that MM. Orfila, Ollivier, and Drogartz, observed the cerebellum presented more evidences of lesions than the other parts of the nervous system. Another argument which probably would be advanced by phrenologists in favour of the affection of the cerebellum of this drug is the observation of Trousseau, that the sexual feelings are usually excited by it.

Serullas found, in his experiments on animals, that in some cases life could not be prolonged by artificial respiration, and that after death the heart could not be stimulated to contract. These and other reasons seem to show that nux vomica exhausts the irritability of the heart. But in all probability this viscus is affected only secondarily, the essential and primary action being on the nervous system.

Thirdly, what kind of action does nux vomica set up in those parts of the nervous system on which it acts?—As the muscles receive from the nervous system a preternatural stimu-

lus to action, it is presumed that this system (or at least certain parts of it) is in a state of excitement or irritation. In one case mentioned by Mr. Watt, there was observed softening of the lumbar portion of the spinal cord; and in the case reported by MM. Orfila, Ollivier, and Drogartz, the whole cortical substance of the brain, especially of the cerebellum, was softened. Andral and Lallemand have both observed that this remedy in some forms of apoplexy produced symptoms indicating ramollissement.

Fourthly, does nux vomica or its active principles become absorbed?—Several reasons, some of which have been before alluded to, may be adduced in favour of the affirmative of this question. Thus the blood of animals under the influence of this poison has been found to be poisonous (though Messrs. Morgan and Addison deny that this was the case in their before-mentioned experiments). Moreover, the activity of this drug seems to be in the ratio of the absorbing power of the part.

Fifthly, in what manner is death produced by nux vomica?—Frequently by the stoppage of respiration, in consequence of the spasmodic condition of the respiratory muscles. In other cases, death seems to arise from excessive exhaustion of the nervous power.

Uses.—I now proceed to notice some of the uses of nux vomica.

1. *In paralysis.*—Of all the diseases for which nux vomica has been employed, in none has it been so successful as paralysis; and it is deserving of notice, that this is one of the few remedies whose discovery is not the effect of mere chance, since Fouquier was led to its use by legitimate induction from observation of its physiological effects. That a remedy which stimulates so remarkably the muscular system to action should be serviceable when that system no longer receives its accustomed natural stimulus is, *à priori*, not astonishing. Paralysis, however, is the common effect of various lesions of the nervous centres, in some of which nux vomica may be injurious, in others useless, and in some beneficial. It is, therefore, necessary that I should point out to you under what circumstance this remedy is likely to be advantageous or hurtful.

A very frequent, and, indeed, the most common cause of paralysis, is hæmorrhage of the nervous centres. Blood may be effused on the external surface of these centres, into their cavities, or in their substance, the latter being by far the most common case, in the proportion, according to Andral, of 386 out of 392 instances of cerebral hæmorrhage. It is superfluous for me to say that the radical cure of these cases can be effected only by the

removal (that is, absorption) of the effused blood. Now the process by which this is effected is almost entirely a natural one: art can offer no assistance of a positive kind, though by the removal of impeding causes she may be at times negatively useful. Nux vomica can, in such cases, be of no avail; on the contrary, it may be injurious.

The part immediately surrounding the sanguineous clot is usually much softened, a condition formerly regarded as the effect of the effusion. But Lallemand has satisfactorily shewn that it often, though not invariably, precedes the hæmorrhage. This softening, or *ramollissement*, as the French term it, is, according to the same authority, a constant and necessary result of an acute or chronic irritation; but the facts at present known do not warrant this generalization, since cases occur which apparently are unconnected with irritation. For this softening art can do but little; we have, in fact, no particular or uniform treatment. If we can connect with it any increased vascular action, of course blood-letting and the other antiphlogistic means are to be resorted to; whereas if the reverse condition of system exist—marked by great languor and debility, tonics and stimulants may be administered. Nux vomica in these cases offers no probability of benefit; on the contrary, we might suspect, that as it irritates the spinal cord, it might probably have the same effect on the brain, and hasten the production of softening. Now experience seems to confirm our theoretical anticipations. Andral relates the case of a man who was hemiplegic, in consequence of an old apoplectic attack. A pill containing only one-twelfth of a grain of strychnia (the active principle of nux vomica), was given him, and it produced a strong tetanic stiffness of the paralysed members. The following day he complained of pain in the head, on the side opposite to that paralysed; his intellectual functions were weaker, and his hemiplegia was increased; in fact, he had all the symptoms characterising softening of the brain. It is, therefore, probable that the strychnia set up an inflammatory condition of the nervous substance around the apoplectic deposit, and that this condition was the precursor of ramollissement. When, therefore, nux vomica is employed in those cases of paralysis which are connected with inflammation of the brain or spinal marrow, it is very likely to increase the evils it is intended to mitigate. Lallemand, in his *Recherches anatomico-pathologiques sur l'Encéphale*, reports two cases in which this drug, administered against cerebral maladies, occasioned convulsive movements, which continued until death. On opening the

bodies, the cerebral substance surrounding the sanguinous clot was found disorganised and exceedingly softened. These remarks therefore, will, I trust, suggest some useful reflections as to the use of this powerful drug in paralysis, and prevent its indiscriminate use in all cases of this disease.

But there are cases in which paralysis, arising from cerebral hæmorrhage, may be advantageously treated by *nux vomica*. The blood which is poured out in the apoplectic cell has at first a gelatinous consistence, some of it still remaining fluid. "Somewhat later," says Andral, "twelve or fifteen days after the attack, for instance, the coagulum is found to be firmer and more circumscribed; later still, it becomes white or yellow, and is surrounded by a brownish-red fluid. The walls of the containing cavity are smooth, and lined with a delicate membrane. The surrounding cerebral substance in some cases retains its natural appearance, and in others is altered both in colour and consistence. As the interval between the effusion and the examination increases, the coagula gradually disappear." The cyst is now found to contain a serous fluid, occasionally having a few cellular bridges running from one side to the other; and nature subsequently attempts to get rid of the cyst by producing adhesion of its sides, leaving only a linear cicatrix. Now it is well known, that by long disuse of some of the voluntary muscles, the power over them becomes gradually diminished; and it appears that occasionally in cerebral hæmorrhage, after the absorption of the effused blood, the paralysis remains, as it were by habit. In these cases the cautious employment of *nux vomica*, or of its active principle, may be attended with beneficial results, by favouring the return both of motion and sensation.

But paralysis, like some other diseases of the nervous system, may exist without our being able to discover after death any lesion of the nervous centres; and it is then denominated a functional disorder, as if there were actually no organic lesion. To me, however, the fact of the lesion of action is a convincing proof that there must have been an organic lesion of some kind, though we see nothing. "It is highly probable," says Andral, "that some organic lesions do exist in such cases, though they escape our notice." Be this as it may, experience has fully established the fact, that *nux vomica* is more beneficial in those forms of paralysis usually unaccompanied with lesions of structure, such, for example, as paralysis resulting from exposure to the influence of lead and its various compounds. Thus, of ten cases of saturnine hemiplegia, treated by *nux*

vomica or its active principles, and which are mentioned by Bayle in his *Traité Thérapeutique*, three were cured, and three ameliorated.

As hemiplegia more frequently depends on cerebral hæmorrhage than some other forms of paralysis, so it is, for the most part, less amenable to remedial means. Thus, while out of twenty-six cases of paraplegia, nineteen were cured by *nux vomica* or its active constituents, yet in thirty instances of hemiplegia only thirteen were cured. In six cases of general paralysis (that is, paralysis of both sides at once), four were cured by this remedy. In the paralysis which sometimes affects the muscles of certain organs, *nux vomica* (or strychnia) has been employed with advantage. Thus a case of amaurosis, accompanied with paralysis of the eye-lid, is said to have been cured by it; and several cases of incontinence of urine, depending on paralysis, or diminished power of the muscular fibres of the bladder, have also been benefited by the same means.

2. *Lesions of sensibility.*—The good effects obtained from the use of *nux vomica* in paralysis have led to its employment in certain functional lesions of the organs of sensation. Hitherto, however, the trials have not been numerous, nor remarkably successful. In amaurosis benefit has been obtained in some few instances; and where no organic lesion is appreciable this remedy deserves a trial. The endermic method of using it has been preferred. Small blisters covered with powdered strychnia have been applied to the temples and eyebrows. The remedy causes sparks to be perceived in both eyes, especially the affected one; and it is said the more of these, the better should be the prognosis: moreover, the red-coloured sparks are thought more favourable than sparks of other colours.

3. *In other affections of the nervous system.*—*Nux vomica* has been used in chorea, hysteria, epilepsy, and hypochondriasis, with occasional benefit. Of course it is only applicable in the absence of irritation or inflammation of any of the nervous centres. I have seen it very serviceable in that shaking or trembling action of the muscles produced by habitual intoxication.

4. *In affections of the alimentary canal.*—On account of its bitterness *nux vomica* has sometimes been resorted to as a tonic and stomachic in dyspeptic cases, more especially when the symptoms are supposed to arise from, or be connected with, a diminished power in the muscular fibres of the stomach. In dysentery, particularly when of an epidemic nature, *nux vomica* has gained some reputation. Thus Hagstrom says he has proved its value in some hun-

dreds of cases of this disease. Hufeland employed it in one hundred and forty cases of epidemic dysentery with great benefit, most of the patients being cured on the second or third day. In *prolapsus of the rectum* Dr. Schwartz has recommended the use of this remedy, which he has employed for ten years, both in adults and children, with great benefit. One or two grains of the alcoholic extract are to be dissolved in two drachms of water; and of this solution he gives to suckling infants two or three drops; older children, from six to ten or fifteen drops, according to their age.

5. *In impotence.*—The excitement of the sexual feelings which Trousseau has seen produced by nux vomica, led him to employ this remedy against impotence; and he has found it successful both in males and females. In some cases, however, its good effects were observed only while the patients were taking the medicine. A young man, 25 years of age, of an athletic constitution, who had been married for eighteen months without having any other than almost fraternal communications with his wife, acquired his virility under the use of nux vomica, though he again lost it soon after leaving off its employment.

6. *Other uses.*—Besides the cases now mentioned, nux vomica has been employed in intermittents, intestinal worms, nervous colics, asthma, &c.

Modes of exhibition.—Nux vomica may be exhibited in the form of powder, tincture, or alcoholic extract. The dose of *powd red nux vomica* is two or three grains, gradually increased. Fouquier has sometimes increased the dose to fifty grains.

The *tincture of nux vomica* is ordered, by the Dublin College, to be made by digesting two ounces of scraped nux vomica in eight ounces of rectified spirit of wine,—from five to ten drops being given at a dose. This preparation is sometimes used as an embrocation to paralysed parts, and its good effects in this way seem increased by combining it with ammonia.

The *alcoholic extract* may be prepared by the evaporation of the tincture; but in the Dublin Pharmacopœia proof spirit is employed in its preparation. It is given in the form of pill, beginning with one grain for a dose, and gradually increasing the quantity.

It is somewhat surprising to find no preparation of nux vomica (strychnia excepted) in the new edition of the London Pharmacopœia just published.

Antidotes.—In the event of poisoning by nux vomica, the best method of treatment is the following. Evacuate the stomach as speedily as possible,—by the stomach-pump if at hand, and in the absence of this by emetics (of sulphate of zinc or sulphate of copper.)

As yet we know no certain chemical antidote for this poison; for several reasons lead me to doubt the value of iodine, bromine, and chlorine, recommended by Donné. On theoretical grounds I should expect infusion of astringent substances (as of galls) would be serviceable—an opinion in which Buchner coincides. According to Emmert's experience, vinegar and coffee increased the effects of the false angustura bark, and, therefore, it is advisable to abstain from using them in poisoning by nux vomica.

To relieve the spasms narcotics may be employed. Sachs and others have recommended opium for this purpose. According to Dr. Christison *concia* is the counterpart to strychnia, and, hence, probably might be employed with advantage in poisoning by the latter, or by substances containing it. As the action of *concia* and hemlock is, according to the same authority, identical, the latter will be a convenient substitute when the former cannot be procured.

Detection of nux vomica.—Nux vomica, unlike opium and some other vegetable poisons, may often be recognised in the stomachs of persons poisoned by it; and, therefore, it is of some importance to establish its characters. In a case of poisoning by this substance which occurred in France, MM. Orfila and Barruel were requested by M. le Procureur du Roi, to examine a parcel marked *mort-aux-rats* (rats-bane), containing a fallow grey powder, and which was found on the deceased's bed; and also to examine the contents of the stomach. The following extract from their report shews their mode of proceedings, and by which they were able to recognise the powder as that of nux vomica:—

1. *Characters of the powder of nux vomica.*—It has a fallow grey colour, a bitter taste, and a peculiar odour analogous to that of liquorice. Thrown on burning coals it inflames when the temperature is very high; but when lower, is decomposed, evolves a thick white smoke of a peculiar odour, and leaves a carbonaceous residuum. Concentrated sulphuric acid blackens it. Nitric acid communicates to it a *deep orange-yellow colour*. By boiling it for a few minutes in distilled water, there is obtained a yellowish, opaline, bitter liquid, whose colour is deepened by ammonia, and becomes reddish-yellow by nitric acid. Tincture as well as infusion of nut galls causes a whitish precipitate. If the powder be digested with boiling water acidulated with sulphuric acid, the filtered liquor is turbid and slightly yellow. Nitric acid, after some minutes, reddens it; ammonia makes it brown, and precipitates blackish flocks.

2. *Characters of powdered nux vomica found*

in the stomach.—In the stomach and duodenum was found a greyish liquid. It was mixed with very dilute sulphuric acid, and boiled for ten minutes: by this means a yellowish liquid was obtained, which became of a *deep orange-yellow colour* by the addition of nitric acid. Its taste was acid, and sensibly bitter. After having saturated the excess of acid by carbonate of lime, the liquid was evaporated to dryness, and the residuum treated by successive portions of alcohol; the different portions of which being mixed, were found to possess a hot acrid taste, very similar to that of very concentrated alcohol, without at first evincing any bitterness; but subsequently this was developed. Evaporated to the consistence of syrup, the residuum had a bitter taste, similar to that of brucia and strychnia, and became *deep orange-yellow* coloured by nitric acid, and formed a flocculent precipitate by ammonia. At the end of two days the bottom of the capsule was covered with very visible crystals of strychnia.

In addition to this account, taken from the report before alluded to, I may add, that the green colour produced by the salts of iron, as well as by the cupreous salts, with an infusion or decoction of *nux vomica*, are important characters.

CLINICAL LECTURES,

DELIVERED AT THE

MEATH HOSPITAL AND COUNTY OF DUBLIN INFIRMARY,

During the Session 1836-7.

BY PROFESSOR GRAVES.

LECTURE I.

Introduction—Connexion between Diseases of different Organs; between Arthritis, Jaundice, and Urticaria; between Periostitis produced by abuse of Mercury, and Hypertrophy of the Liver—Details of cases illustrating this connexion—Its explanation—Hypertrophy of the Liver produced by Scrophula—Enlargement and Inflammation of the Liver after Scarlatina—Importance of recognising this disease.

ALTHOUGH it is customary to state, at the commencement of a course of clinical lectures, the mode of instruction the teacher intends to pursue, it is not my intention to dwell on the plan of communicating medical information adopted in this hospital, or the facilities, advantages, and inducements which it affords. I have spoken so often on the subject, and my opinions have been so long before the public, that I do not feel it necessary to enter into details

on the present occasion. It is extremely satisfactory to me to find that the mode of clinical instruction which I introduced at this hospital in 1822, has been adopted in most of the Dublin hospitals, and in many of the medical institutions of Great Britain. It is now several years since I delivered an introductory lecture at the old Meath Hospital on the Coombe, setting forth the insufficiency of the clinical instruction imparted to the students in Dublin at that period, and proved, to the satisfaction of my auditors, that the German mode was infinitely superior. The lecture I then delivered was subsequently published in the *LONDON MEDICAL GAZETTE*. This mode I soon afterwards introduced at this hospital, and it is a source of extreme gratification to me to find it adopted and approved of by so many medical teachers of established reputation. It is recommended at once by its simplicity, and by its admirable fitness for fulfilling the purposes which it is intended to accomplish. A card is suspended over each patient's bed, on which is recorded the date of his admission, the history of his case, and the daily treatment, dietetic as well as medical. These cards remain in the wards until the patient leaves the hospital, and in this way any gentleman who wishes to observe the progress and termination of any particular case, can easily make himself master of its principal features, and the different remedial agents employed for its alleviation or removal. I shall not dwell any longer on this subject, as my object at present is to excite you to a diligent cultivation of the many and valuable opportunities which this institution affords. Go round the wards, and observe the numerous and varied forms of disease they present. You will find in them many examples of morbid affections interesting alike to the student and the practitioner, and capable of affording practical lessons of inestimable value. He must be sadly deficient in zeal, attention, and every other quality necessary to constitute the accomplished and successful physician, who does not feel himself excited to study by what is there presented to his observation.

Did time permit, I should be glad to furnish you with an outline of the most interesting cases which have been under treatment in our wards for the last three months, in order to give you some idea of the prevailing forms of disease, and their most remarkable modifications; and in this way to prepare you for studying with more advantage the cases that may come under your notice during the ensuing session. We have had some cases of extreme interest during the months of August,

September, and October; but I fear even a brief review of these would occupy more time than I could conveniently devote to the subject, and would interfere with matters of paramount importance. I have, however, kept records of these cases, and shall feel most happy to show them to any gentleman who may be anxious to peruse them. Before I proceed to make any observations on the cases at present in our wards, I shall give a statement of the most remarkable results obtained in the chronic wards, and the most important pathological observations made in the fever wards, during the last three months. This will occupy but two or three lectures, and in the interim I shall each day direct your attention to any thing of importance which occurs in the wards. It is my intention at present to limit myself to the illustration of some points connected with pathology, and to dwell merely on those prominent features of disease which bear a special reference to practical medicine; I shall afterwards give some lectures on fever. I shall not enter into any disquisition as to the origin and cause of fever; for these matters you must consult your books: all you can expect from me is to endeavour to impart to you some useful hints on the treatment of fever.

In order to acquire a correct and available knowledge of human pathology, and to extend the range and confirm the accuracy of diagnosis, it is of the utmost importance to observe attentively the connexion between the diseases of certain organs or systems of the body. You are aware that some organs, when labouring under disease, are apt, after the disease has continued some time, to implicate other organs, giving rise to various deranged conditions, which are developed, sometimes simultaneously, but in general consecutively, and in sequence. I have already pointed out several diseased actions thus associated together, each forming a link in the morbid chain. Now it is of the greatest importance to study each link, and ascertain the nature of its connexion, so as to have a distinct conception of the whole. Last session I directed the attention of my class to a train of morbid phenomena sometimes observed co-existing with arthritic inflammation. A person labouring under inflammation of the joints gets an attack of hepatitis, accompanied by jaundice, and this is followed by urticaria. I have observed this sequence of disease in eight or nine cases. The first was in a gentleman residing in Lower Mount-Street, whom I attended with Dr. Cheyne. This gentleman, in consequence of exposure to cold, was attacked with arthritic inflammation and fever. After he had been about ten days

ill, he became suddenly jaundiced, and in a day or two afterwards a copious eruption of urticaria appeared over his body and limbs. Exactly the same train of phenomena, and in a similar order of succession, were observed in a man treated in the Meath Hospital in 1832. A short time before this, I had been attending a medical friend in Baggot-Street, who had been affected in the same way; and I mentioned to the class, as soon as I perceived the man was jaundiced, that he would most probably get urticaria. I made a similar prediction in a case which occurred recently in our wards, and it was verified by the event. Now this is not a mere fortuitous occurrence; the various symptoms must be connected in the relation of cause and effect. It is interesting to bear this in mind, and it is besides of considerable importance to the practising physician; it enables him to predict the appearance and form of disease, and inspires his patient with confidence in his opinions and judgment.

There is another sequence of disease, not unfrequently observed, but of which the connexion has not been hitherto noticed by any writer, as far as I can ascertain. About two years since, Mr. Crampton and I were consulted by an English gentleman, who had been ill for a considerable time. The history of his case from the commencement was this:—Three years previously he had venereal,—used and abused mercury,—was exposed to cold, and got periostitis. He now got into a bad state of health, used mercury a second time, obtained some relief, and then relapsed again; finally, after having used mercury three or four times, he was attacked with mercurial cachexy, became weak and emaciated; the periostitis degenerated into ostitis, producing superficial caries and nodes of a bad character; he had exfoliation of the bones of the cranium, and rupia, and was reduced to a most miserable state. Under our care the symptoms gradually disappeared; he recovered to all appearance, and even got fat. He then caught cold and relapsed again. At last his liver became engaged; he was attacked with hypertrophy of the liver, ascites, and jaundice, and died soon afterwards. Here, then, we have venereal, abuse of mercury, periostitic inflammation, abuse of mercury followed by exacerbation of the periostitis, and the establishment of mercurial cachexy, and the history of the case is wound up with hypertrophy of the liver. This was the first case in which I had observed this concatenation of diseases; since that period I have seen a similar train of morbid phenomena, twice in private practice and once in hospital. First we have

abuse of mercury, then periostic inflammation and mercurial cachexy, and the scene is closed by morbid enlargement of the liver. Now I do not look upon this sequence as merely fortuitous. The diseased actions are, I think, related as cause and effect, and each successive condition is consequent on the previous one. It may not be amiss to mention here some curious circumstances observed in the case to which I have just alluded. While this gentleman's liver was enlarging, there was no tenderness of the right hypochondrium on pressure. I have observed the same absence of tenderness in all the cases of this description which I have witnessed. The gentleman could bear pressure over the hepatic region without any inconvenience, and yet the liver was so enormously increased in size, that its inferior margin extended almost down to the pelvis. What is equally remarkable, he had no fever, and the tongue was perfectly clean and moist during the whole course of the hepatic affection. In my observations on a case in the fever ward, I remarked a few days since that some persons were too hasty in drawing inferences from the state of the tongue as to the existence of affections of the digestive organs. I shall not touch on this point, however, at present, and shall merely observe that this gentleman's tongue was perfectly clean and moist, notwithstanding the morbid condition and rapid growth of the liver. Another curious circumstance was, that during the hepatic affection, digestion appeared to go on very well, at least so far as the formation and due expulsion of *fæces* are concerned. The alvine evacuations were regular, and the matter discharged presented the form and consistence of that which is passed by a person in good health. But there was a peculiarity in it to which my attention was first directed by the patient, who was an intelligent and observant person. The cylinder of *fæcal* matter was composed of parts differing in colour and appearance: two or three inches consisted of pale clay-coloured substance; and immediately after this another portion, of about the same length, was observed, presenting the ordinary bilious or brown colour of natural excrement; and then again another mass of clay-coloured matter, without any obvious trace of bile. This appearance I have now frequently witnessed; and the inference to be drawn from it is this,—that in such forms of hepatic disease the functions of the liver are performed, as it were, intermittently; it secretes bile during a certain period of the digestive process, then stops, and then secretes again.

This peculiarity is noticed in many dis-

eases of the liver; and it is important to remark, in attempting to explain the *rationale* of these hepatic affections, that in no disease of the liver is this symptom more frequently observed than in the *scrofulous*. *Scrofulous* disease of the liver is that state in which there is an increase of size in the organ, with induration and imperfect secretion, but without any remarkable tenderness. This condition in children is accompanied with irritability of the digestive organs, fretfulness, emaciation, loss of sleep, and impaired nutrition. The little patient becomes what is termed "pot-bellied," and labours under thirst, debility, and febrile excitement. This has been frequently called *remittent fever*, and disease of the mesenteric glands, but in my opinion unjustly. It is only a form of general cachexy connected with the *scrofulous* diathesis, affecting secretion and nutrition in general, and the digestive and biliary systems in particular. It would be quite wrong to imagine that, in this form of disease, the liver is the cause of the whole train of morbid phenomena; it is merely affected in common with other organs, and forms only an individual feature in the group of symptoms.

Now in this form of *scrofulous* cachexy, where you have diarrhoea, emaciation, fever, thirst, and restlessness, the liver is frequently affected in the manner already described; and in the loose stools of such a child, you will find one part bilious, another part clay-coloured; they will be yellow to-day, and pale the next, accordingly as the liver secretes bile or suspends its functions. But in this instance, I repeat that the liver is only one of many organs affected by the same general cachexy. Could we ascertain the derangements of other secreting organs with the same facility, it is very probable we should find similar evidences of the morbid influence which pervades the whole system.

This view of the question shews that you are not to expect to succeed in removing the disease by the use of calomel or any other mercurial preparation. Many of those persons whose practice is little better than routine, when called to treat a case of this description, first examine or inquire as to the nature of the alvine evacuations, and fixing on the single symptom of deficiency of bile, immediately prescribe calomel, to be repeated or continued until the secretion of the liver is established; but they forget that this state of the biliary system depends on the general state of health, and that the absence of bile is the consequence, and not the cause, of the disease. Almost all the organs of the body are affected; and though calomel may restore the secretion of the liver for a time, it cannot bring back the organ to its

ral state, or cure the disease. The remedy is to be remedied in a different manner: the secretions (and that of the liver among the rest) are to be improved by change of air, by an appropriate diet, by exercise, tepid or cold bathing, and the use of those remedies which are adapted to modify or correct that state of the system on which the general derangement depends.

My observation of such cases has led me to a train of reflection respecting the occurrence of the same order of symptoms in persons who have been injured by the use of mercury. Many persons who get the habit of employing mercury injudiciously, fall into what has been termed the mercurial cachexy, in which there is a general unhealthy state of the organs. A person who has fallen into this state very much resembles a scrofulous person, and is not to labour under the same emaciation, impaired nutrition, irritability, feverishness, and the same sort of cutaneous, glandular, and periostitic affections. The mercurial cachexy is very like the scrofulous, and attacks very nearly the same organs and tissues. Hence the difficulty of curing affections of the liver, and other organs, when they are the result of a depraved habit. This is the key to the explanation of those horrible ravages which we frequently witness in cases of mercurial disease complicated with mercurial cachexy—a state of constitution which is closely allied to the scrofulous. You frequently meet with this consecutive affection of the liver in cases of morbus coxæ, where the patient has been labouring for years under ulceration of the joint. The growth of the rest of the body appears retarded, the patient is stunted and emaciated, while the liver increases rapidly in size.

It was from observing the occurrence of liver disease in persons labouring under the scrofulous cachexy, that my attention was first turned to its occurrence in persons broken down by long or injudicious courses of mercury.

In short, gentlemen, as to the curability of hepatic affections of this kind. I believe that it is always an unpromising kind of disease; but persons of originally good constitution, and under the age of thirty, will generally escape, if treated judiciously, and with proper care and attention.

Some months ago I attended, with Mr. Marsh, a young gentleman labouring under this affection, as a consequence of the abuse of mercury. We found him very much emaciated, and labouring under considerable enlargement of the liver, with increasing ascites. He had also great accumulation of blood to the abdomen, hæmorrhæa, and hæmorrhoids. By strict attention to his bowels, a well-regulated

diet, change of air, and the use of taraxacum, conium, and hydriodate of potash, he was ultimately cured, after an illness of nearly two years, during which the liver had grown to an enormous size. I may state that he is at present in good health, and that the liver is nearly reduced to its natural dimensions. It may be proper to add, that this gentleman's age is about four-and-twenty.

I observed one circumstance in the progress of this case which is worth noting. He was suddenly attacked with a papular form of purpura, accompanied by much tingling and itchiness, and answering to the description given of *Purpura urticans*. This peculiar eruption was very troublesome at night, and formed several successive crops, which altogether lasted a month. It occupied the extremities, upper and lower, and was very abundant on the latter. This gentleman wore a bandage, to relieve a varicose state of the veins of the left leg. Now the eruption never appeared in the parts subjected to the pressure of the bandage, although it was very thick immediately below and above those parts.

In persons below thirty the liver may become enlarged to a very considerable extent, and yet return again to its natural size under proper treatment. I could point out several persons in Dublin in whom the liver had been so much enlarged that I thought their cases hopeless, and yet they have recovered, and are at present in the enjoyment of good health. The process by which the organ returns to its natural state and dimensions is generally slow; in two or three cases it occupied a space of time varying from one to two years. I attended a gentleman some time ago with Mr. Carmichael; and from the history of the case, as well as the symptoms present, we were induced to look upon it as incurable; and yet the patient has completely recovered. Mr. Macnamara and I attended a lady who had a very remarkable enlargement of the liver, but in the course of a year the viscus diminished so much in size, as to be very little above the normal dimensions. This is a matter of no common interest, for cases of this description have been generally looked upon as beyond the reach of medical aid. You should therefore be very careful in your prognosis of such cases, and not give them up at once as incurable.

I may observe in conclusion, that it is entirely as the result of the cachectic habit that this enlargement of the liver is observed. I have assumed this principle as the basis of my argument, and I think it is founded in fact and truth. It is also curious to observe, that the same cachectic

state which gives rise to emaciation and decay of the body, generally occasions hypertrophy of some particular organs. What we most commonly observe in such conditions is, general wasting of the system, accompanied by increased morbid nutrition in certain organs. This appears to be the general law. You perceive that in the explanation I have given, I have supposed that enlarged liver is the result of a general cachectic state of the system, and it is of importance to recollect that this state may be brought on by the injudicious exhibition of mercury, or by carrying mercurialization further than the constitution will bear. In this instance we are compelled to allow that our practice may furnish weapons to be turned against us by the disciples of homœopathy. It cannot, however, be denied, that the immoderate use of mercury has been productive of liver disease. The late Mr. Hewson pointed out this to the attention of those who visited the Lock Hospital while under his care. At this period it was the custom to salivate every patient, and keep him under the full mercurial influence for a month or two; and it frequently happened that, just as the mercurial course was finished, the patient got disease and enlargement of the liver. Were I inclined to theorize, I might perhaps offer some fanciful hypothesis in explanation of this occurrence, and might trace some connexion between the stimulant effects of mercury on the liver, and the subsequent hypertrophy. I shall, however, content myself at present with noticing the fact, and leave the explanation to my juniors, who always explain matters, according to my observation, much more readily than their seniors.

There are also other diseased states of the system, in which we have enlargement and morbid alteration of the liver. I can point out to you four different states of the system in which hypertrophy and disease of the liver forms one of the results of the general affection of the system. The next of those to which I shall direct your attention is scarlatina. Those who have attended the wards during the past month have seen examples of this. We have observed during the same week two patients labouring under scarlatina, who got disease of the liver and jaundice. One of the patients, a little boy, was attacked with the disease in an extremely violent form, accompanied with high fever, and a very remarkable eruption. In a few hours after the exanthema appeared, the entire cutaneous surface was dyed of a brilliant red, in fact, the skin looked as if it had been painted over, and there was not a single spot free. In cases of this kind the violence of the cutaneous inflammation is

sufficient to kill, without any other unfavourable complication, and the patient seldom lives more than three or four days. You observed in this case, that the whole epidermis peeled off. But what I wish to direct your attention to is, that this boy after two days had evident symptoms of disease and enlargement of the liver. A young man, in the same ward, had also an attack of scarlatina, but in a milder form. On the third day he likewise got inflammation of the liver, but was cured by general and local antiphlogistic treatment. You are aware that scarlatina is one of those diseases in which a train of unfavourable sequelæ are apt to remain after the removal of the original complaint. Persons, after recovering from the exanthematous fever, will sometimes get into a bad state of health, and instead of convalescing, become restless and feverish towards evening—have an irritable jerking pulse, hot skin, derangement of the digestive organs, diminished urinary secretion, and finally become dropsical. Now, from observing the supervention of hepatic disease in such cases, both in hospital and private practice, my attention has been directed to the liver, and I never omit making an examination of that organ when called to treat those symptoms which are looked upon as the sequelæ of scarlatina. In many of these patients I have found the liver in a state of inflammation of rather a chronic character, and without any of that remarkable pain or tenderness which characterizes acute hepatitis. But still it was inflamed, as proved by the benefit derived from local antiphlogistic means, and, moreover, its condition appeared to retard and prevent convalescence. Not long since, a friend of mine, a very intelligent practitioner, who was attending a case of this description, and had tried a variety of remedies without any benefit, was very much surprised when I drew down the bed cloth and showed him that the liver was diseased. He had not thought of the existence of any thing like an hepatic affection, and was very much surprised that his treatment had proved so ineffectual. By the use of leeches to the right hypochondrium, the employment of mercury, and a proper regulation of diet, the patient was soon relieved, and the fever, thirst, and anasarca, quickly disappeared. In cases of this kind the hepatic affection is the result of the general inflammatory diathesis superinduced by scarlatina. You are all aware that nothing is more common, after scarlatina, than inflammation of various organs. Thus some persons are attacked with pleuritis, some with pneumonia, others with inflammation of the liver. Many persons continue in a valetudinary,

state after the eruption has declined; they do not convalesce according to our expectations; the pulse remains rather quicker than natural; the bowels are deranged; the appetite bad; thirst urgent, and urine scanty. In many of these cases you will find that there is a species of chronic hepatitis going on, which keeps up the feverishness and retards convalescence. This is a point of great importance, to which I am the more anxious to draw your attention, because even the latest writers on scarlatina have either entirely omitted or very insufficiently noticed it.

OPPOSITE MODES OF PRACTICE IN THE TREATMENT OF INFLAMMATION.

To the Editor of the Medical Gazette.

SIR,

I BEG to be allowed to reply to Investigator's remarks upon what he is pleased to denominate "the new-fangled doctrines *."

It should first be observed that your correspondent assumes a name which does not belong to him; it is evident that his proper name is "Conservative," for he complains that "long-cherished medical theories and modes of practice are (being) abandoned." While charging me with *inconsistency*, he does not perceive his own: he denominates himself an Investigator, and pretends to be a matter-of-fact man, by denouncing any new principles of practice as "new-fangled," and proofs of a "professional mania." In what manner should a person prepare himself in order *consistently* to pronounce his *dictum* against either new or old doctrines in medicine? Certainly by patient inquiry, and by the test of facts. But the *soi-disant* Investigator opposes his *mere words of the moment* to *facts*, which have required many years to collect and investigate. To use no harsher expression, it is neither philosophical nor fair in an individual who is acquainted with only one side of the question, to condemn the conclusions of those who have examined both: for my own part, I should be very reluctant to raise prejudices against Mr. Radley's method of treating fractured bones, merely because it was new to me: nay, further, since he has practised according to the old "che-

rished" system as well as the new, and asserts that the latter is attended with decided advantages over the former, and confirms them by the relation of cases. I certainly should, if I became the subject of fracture, request that his plan of treatment might be adopted.

Then in allusion to Investigator's denouncement of homœopathy as another "mania;" how much more like a true Investigator would he have been if he had first made trial of it.

And now with regard to my own "mania" of treating inflammatory diseases upon a system opposed to the current practice of the day, I beg to state that during the first ten years I was engaged in the medical profession, I pursued the strict antiphlogistic system in the treatment of inflammatory diseases, having been taught so to do, and that when I met with fatal cases I in general ascribed the want of success to not being bold enough in the abstraction of blood; and this notion became so strong in my mind, that during two years previous to my relinquishing this mode of practice altogether, I phlebotomised copiously, and at very short intervals, in order to anticipate and prevent the reaction which so frequently ensued; this practice, however, was attended with still more fatality and vexation. I was then advised by the late Dr. Armstrong to administer one or two doses of calomel and opium, after each abstraction of blood, which certainly did considerably allay the inordinate vascular action. In the spring of 1822, I had an interview with Dr. Darwin, of Shrewsbury, relative to a patient: in conversation, he stated that he considered all pulsations above 90 or 100 in a minute were indications of debility, and not of the degree of inflammation, to which I fully assented, and mentioned Dr. Armstrong's method of controlling this irritable action, when Dr. Darwin replied that if I could thoroughly examine the effects of bleeding, I should not long remain so strong an advocate for the practice.

Although these were the only remarks which occurred between Dr. Darwin and myself upon the subject, yet, having already had the greatest reason to doubt the efficacy of general bleeding as a remedy, I immediately turned my attention to the other side of the question, and was soon convinced by the happy results of this new system of practice,

* MED. GAZ. present vol. p. 202, ante.

that the old "cherished" system was founded in error. I have ever since—during fourteen years—been observant of their respective merits; and having well considered them, I felt justified in recently presenting in the *Lancet* this "new-fangled doctrine" to the consideration of the profession, and think that no one can with propriety condemn it until he has proved it to be fallacious: but since Investigator has not regarded this just order of proceeding, he is bound in justice to make a fair trial of the practice he so prematurely condemns, and to report the results.

There is but one point among Investigator's remarks deserving serious notice, and that not on account of its arising out of an impartial inquiry, but on account of its being a misrepresentation, as the following quotations will prove. First his quotation blended with his remarks. "The medicinal treatment, we are told, depends much upon the character of the inflammatory fever. When the general circulation is inordinately increased, and when considerable pyrexia attends subacute inflammation, sedative medicines, such as tartarized antimony and digitalis, are recommended, though upon what principle it is difficult to imagine; for everyone must, I think, perceive that if it be right, in the dietetic treatment of the constitution, to increase the general circulation, by the fearless administration of milk, beer, wine and water, eggs, and good broth, that it cannot at the same time be proper in the medical treatment, to lower the vascular action by means of tartarized antimony and digitalis. But it happens that this treatment can seldom be put into execution; for when emetic tartar is given in doses sufficiently large to produce a sedative effect, it never fails at the same time, to cause severe nausea: so that when a patient is under the influence of that medicine, his stomach, which must be in a very unfit state to receive eggs and broth, will necessarily rebel against those good things, and either refuse them admittance, or eject them soon after their entrance. As far, therefore, as regards the constitution, it must, I think, be plain that the treatment recommended for it by Mr. Searle is inconsistent and often impracticable."

According to the above remarks of Investigator, it is made to appear that it is my practice, in the treatment of

inflammatory diseases, to give food freely with one hand, and tartarized antimony with the other. Why did he not give a full quotation? Because he could not then have indulged in his disingenuous observations; for they are anticipated and answered, as the following full quotation will shew:—

"The medicinal treatment depends much upon the character of the inflammatory fever. If considerable pyrexia attend subacute inflammation, it is evident that the predisposing cause, excitability, is greater than the exciting cause, inflammation. Under these circumstances, febrifuge medicines, especially those of a sedative nature, as tartarized antimony, digitalis, &c. will, in general, produce a beneficial effect. But if, as in acute inflammation, the exciting cause play the greater part, then febrifuge medicines will avail but little. Sedative medicines would appear, *a priori*, to be indicated whenever the general circulation is inordinately increased; but very high and strong arterial action cannot be controlled by sedative medicines, as tartarized antimony and digitalis; for small doses of these medicines have no effect, while large doses occasion vomitings, which are often distressing and injurious to inflamed organs; and unless they produce a uniform sedative effect, they are pernicious, as temporary depression of the circulation induces reaction, and thus defeats the object to be attained; and to nauseate the stomach without subduing the disease is worse than useless, as it renders the patient incapable of taking that nutriment which, of itself alone, would, according to the views which have been already given of the nature of inflammatory fever, tend to diminish the pyrexia.

"The sedative agency of cold may be often employed advantageously, by placing the patient, who should at the same time be thinly clothed, in a current of cool air. No kind of danger need be apprehended from this exposure, unless the phlegmasia have originated from revulsion of blood, occasioned by exposure to cold; then, indeed, to renew the original cause of the disease would be committing the folly of adding fuel to fire. In such cases calomel and opium in combination form an exceedingly useful sedative, producing a general and uniform effect. While they allay inordinate action, they maintain an equal distribu-

tion of blood ; if they fail to induce sleep they compose both mind and body ; they alleviate delirium when it exists, and in other cases prevent its occurrence."

It is clear that I mean by tartarized antimony, digitalis, &c., the whole catalogue of sedative medicines. I placed tartarized antimony at the head because it is most frequently employed by the profession, and because I wished to make considerable strictures upon its use. So far from its being a favourite remedy of mine, I prefer calomel and opium, or any other medicine which will not nauseate the stomach ; in short, I do not believe that ten prescriptions could be produced, in which I had recommended, within the last six years, tartarized antimony as an internal remedy, whilst hundreds might be brought forward of my having prescribed calomel and opium. But let it be supposed that the "&c." had been really omitted, and that I intended to recommend tartarized antimony only, to what cases have I restricted its administration ? To those in which considerable pyrexia attends subacute inflammation. Under what circumstances does this form of pyrexia occur ? The patients are either very young children, or of very delicate constitutions. Under the former, tartarized antimony is never given, nor even thought of, and under the latter the patients are such as habitually take but little food, and when ill, manifest, in general, an insuperable aversion to it. In such cases there can be no inconsistency in administering tartarized antimony. So that if I had made no more comments upon this medicine than those which were convenient for Investigator partially to quote, his charge of inconsistency would, even then, have been perfectly groundless.

Investigator has yet to learn that if nutriment be fearlessly and judiciously administered at the commencement of an attack of intestinal inflammation—when it can, in general, be taken—the inflammatory fever, if it exist at all, will scarcely ever become so high as to merit any special attention, and that the inflammation itself will not often assume a very acute character. If he were a real investigator, he would soon discover that the acute and dangerous characters which sometimes accompany inflammation are almost always owing to the large abstractions of blood, and the pri-

vation of nutriment which the strict antiphlogistic system of treatment enjoins.

Although Investigator is pleased to denominate the system of practice I am advocating "a mania," he will, most probably, on some future day look back with horror, as I now do, on his present favourite and "long-cherished" system, as one which has converted a number of cases of mild into acute and alarming forms of inflammation, which has impaired numbers of good constitutions, and which has destroyed many lives.

I am, sir,

Your obedient servant,

HENRY SEARLE.

Kennington, Dec. 6, 1836.

ON THE
RECENT CASE OF SUPPOSED POI-
SONING WITH UNSOUND BACON.

To the Editor of the Medical Gazette.

SIR,

IN consequence of a report of the inquest held at the Westminster Hospital, on the body of Caroline Jones, appearing in your journal of the 10th inst., in which a verdict was brought in that "the death of the deceased was caused by eating unwholesome bacon," I beg to offer a few observations on the case ; which, previous to admission into the hospital, was under my care.

Caroline Jones, æt. 14, was admitted a patient at the Chelsea Dispensary, on 25th October. As she was too ill to come to the institution, and was confined to bed, I visited her at her own home. She complained much of pain in the back and limbs, and general uneasiness and restlessness. There was considerable headache, a dry and foul tongue, mucous sordes about the mouth, thirst, no appetite, hot skin, quick pulse, cough, with pain in the chest ; over the fore part of which, slight sonorous rattle was general. She had been ill about ten days, and the only cause which the mother then assigned as the origin of her illness, was her having been exposed to fatigue and cold during her journey up from Gloucestershire by the waggon, in which she had slept two nights on the road : two or three weeks had since elapsed. Leeches were ordered to be applied to the chest and

head, and the hair to be cut close. A purgative and diaphoretics were administered. The pain in the chest and cough shortly disappeared, and the headache was relieved. A few days afterwards, she complained of pain in the bowels, with much purging, and there was considerable tenderness of the abdomen on pressure. She had leeches, followed by poultices, applied twice. Small doses of hyd. c. creta, with pulv. ipecac. comp. were given, and subsequently the mist. cretæ, with a few drops of tinct. opii; under which treatment the pain of abdomen and diarrhœa ceased, and she was evidently getting better. On my next visit, after an interval of two days, I found she had been up in the meantime, and had felt tolerably free from complaint, and that her appetite having returned, she had probably indulged it too freely, as the fever had increased, and the pain in abdomen and diarrhœa had returned. I have since learned that on both days, besides meat at dinner, she had taken pickled cabbage, with half a pint of porter and wine. At the solicitation of the mother, who, in consequence of having so young a family, and of the sickness of another daughter, said she was unable to pay proper attention to her, I gave her a letter to the Westminster Hospital, with strict injunctions to guard against cold; but either from being too early at the hospital, or some other cause, she tells me her daughter was kept in the waiting-room for three hours, which, together with exposure to cold in the coach on her way there, no doubt caused an aggravation of the symptoms.

Such is the case, so far as I attended it; and independent of the history, as since given by the father on the inquest, we should have no hesitation in considering it simply as an instance of continued fever, complicated with abdominal affection. The question is, whether that evidence can be so relied on as that we can have no doubt that the fever and subsequent death were solely the result of eating unwholesome meat. At the time when it is stated that all who partook of the bacon were so seriously affected, the eldest son, a boy of about twelve years of age, was under my care for chorea, and was attending the dispensary twice a week with his mother; and although he is said to have suffered from pain and vomiting, no

notice was taken of it to me at the time. During my whole attendance on the girl it was never mentioned; nor in a letter which the father wrote to me during her stay in the hospital, requesting my advice, as she was getting worse, if she might be removed home; nor on my being asked to prescribe for a younger sister a few days after the elder had become a patient of the dispensary; nor was the slightest account given of such an occurrence after her admission into the hospital, till within three days of her death. I can hardly think that on all these occasions, had the symptoms occasioned by eating the bacon been as serious and violent as since stated, it could have escaped recollection to have named it as the probable origin of the disease. That sickness was caused, I do not doubt; but I fully believe, on inquiry, that the effects produced have been much exaggerated, — perhaps unintentionally, — for we know how prone people are to attribute their complaints to any unusual cause. I know not if there be any case on record in which the symptoms produced by eating unwholesome meat so exactly resemble those of continued fever.

Dr. Christison, in his excellent work on Poisons, thus details the symptoms, on the authority of Kerner and others, occasioned by sausages which had become poisonous; and perhaps I shall be excused for quoting the passage entire. "The symptoms of poisoning seldom begin till twenty-four, or even forty-eight, hours after the noxious meal, and rather later than earlier. The tardiness of their approach seems owing to the great indigestibility of the fatty matter with which the active principle is mixed. The first symptoms are, pain in the stomach, vomiting, purging, and dryness of the mouth and nose. The eyes, eyelid, and pupils, then become fixed and motionless; the voice is rendered hoarse, or is lost altogether; the power of swallowing is much impaired; the pulse gradually fails, frequent swoonings ensue, and the skin becomes cold and insensible. The secretions and excretions, with the exception of the urine, are then commonly suspended; but sometimes profuse diarrhœa continues throughout. The appetite is not impaired; fever is rarely present; and the mind continues to the last unclouded. Fatal cases end with con-

is and oppressed breathing, before the third and eighth day. In the period of recovery, the period of convalescence may be protracted to several

The chief appearances on the body are, the signs of inflammation the mucous membrane of the laryngeal canal, whiteness and dryness of the throat, thickening of the gullet, distension of the stomach and intestines; morbid disposition in the windpipe; flaccidity of the heart; and a tendency in the whole body to resist action*."

Similar effects have been produced by

In an account of an accident of the kind given by M. Ollivier, three members of a family at Paris, after eating a pie, were seized with shivering, cold sweats, violent pain in the chest, frequent vomiting, burning, excessive tenderness of the belly, and purging, and colic; but the symptoms did not come on till the day after partaking of the pie; and other members of the pastry-cook who supplied it had been similarly affected. All recovered. In the above case stated by the father that he himself did not disagree with him while eating, the son vomited during dinner; the daughter was taken ill about three days after; and the mother in the fourth day of the night. We know not how the purging was the result of eating the pie, as the father immediately treated them all with calomel. The morbid appearances were those usually found after fatal cases of protracted fever; there was no ulceration of the stomach, as stated in the report of the inquest; but numerous ulcerations were found in the ileum, near the ileo-cæcal valve, one of which had penetrated all the coats of the bowel. On reviewing the whole of the circumstances, I think we ought to pause before placing this on record as an undoubted instance of death proceeding from poison generated in unsound bacilli. I am, sir,

Your most obedient servant,

JOHN BARR, M.D.

Physician to the Chelsea Dispensary.

Coane-Street, Dec. 16, 1836.

SOME REMARKS ON PECTORILOQUY.

To the Editor of the Medical Gazette.

SIR,

IN speaking of pectoriloquy, Laënnec recommended the application of the stethoscope to the larynx and trachea of a healthy individual, as a means of acquiring a good idea of this sign. At this stage of his proceedings pectoriloquy was for him "la transmission évidente de la voix à travers le cylindre"; and having first noticed it in ulcerated cavities from the softening down of tubercles, he appears at that time to have considered such transmission, and such cavities, as essentially connected, although the examples of the larynx and trachea were calculated to excite doubts on this point. If we constantly bear in mind this first strong impression of Laënnec as to the connexion between "ulcerated tubercles",* and the passage of the voice up the tube, we shall find in it an explanation of some of the confusion to be met with in his work, on the subject of pectoriloquy, and which seems not to be altogether banished from the minds of several of his followers.

Subsequent researches, however, proved on the one hand, that "ulcerated tubercles" do not always give transmission of the voice up the tube, and on the other, that this transmission might be produced without any such ulcer; so that he came afterwards to give the name of pectoriloquy to some cases in which there was no transmission of the voice, although he refused it to others in which such transmission was produced by consolidation of the lung surrounding a bronchial tube. Still, however, the passage of the voice up the tube appears to have maintained a high place in the mind of Laënnec; and the undue importance attached to it as a sign has, I think, been a source of much mischief.

The attention of the student has in this way been withdrawn from what is, in my opinion, the most valuable auscultatory sign of a cavern (so far as the voice is concerned — namely, a sensation that the space in which the voice plays is "circumscribed;" such space not existing naturally in the

* "Tubercules ulcérés," an expression of Laënnec which is sufficiently intelligible.

part of the lung from which the sensation is communicated.

To this sign Laënnec has not, I think, given a sufficiently prominent situation; he has not sufficiently insisted upon its perception as the "sine quâ non" of a generally correct diagnosis (by the voice) of a "circumscribed space."

The extension which he gave to the term pectoriloquy, in applying it to some cases where the "transmission de la voix n'est pas évidente," as well as to some in which "la résonnance est très faible," was calculated to create inextricable confusion; and such has been the result. Even in cases of ulcerated cavity in the lungs, where there is a strong resonance under the stethoscope, with or without some transmission* of the voice, these circumstances are perhaps as often connected with the bronchi as with the cavity itself; and not only so, but the modification of sound proceeding from the cavity, may be little or not at all attended to, on account of the stronger resonance in the bronchi. In such cases the auscultator is confirmed in his error, by finding after death the cavity which he had predicted, and the existence of which was in his opinion indicated by what he calls pectoriloquy.

The next case which he meets with presents, perhaps, the same sounds as the last; he confidently predicts the existence of a cavern, but finds to his astonishment, if the patient dies, that there is nothing of the kind.

Now I think such mistakes would be less frequent, if, from the commencement of his auscultatory career, the student's attention were strongly fixed upon the advantage of being able to appreciate the circumstance above mentioned, viz. "the resonance of the voice in a circumscribed space."

The practice so generally adopted of representing auscultation, by implication at least, as one of the most easy studies on which a medical pupil can enter (it being in reality one of the most difficult) is attended with serious disadvantages.

The pupil who has thus been encouraged to commence the study of it with ardour and zeal, is the more mortified

and discouraged when, after having pursued it for years, he finds himself frequently in doubts and difficulties on those very points concerning which auscultation had appeared to hold out the fairest promises.

What is pectoriloquy*?

What is it a sign of?

The chances are that the two first auscultators (not beginners) you meet with, will differ on one or both these points; nor can you be sure that even the most recent authors will be free from variations or contradictions on this subject. Those writers and lecturers, however, who try to allure on our ingenuous youths in the way above mentioned, may prove that they are acting on a principle which has the sanction of antiquity,

"ut pueris olim dant crustula blandi
Doctores, elementa velint ut discere prima."

I remain, sir,

Your obedient servant,

EDWIN HARRISON.

Grove Terrace, Lisson Grove,
Dec. 19, 1836.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALEMBERT.

Elements of Medicine. Vol. I. On Morbid Poisons. BY ROBERT WILLIAMS, M.D., Trinity College, Cambridge; Fellow of the Royal College of Physicians; and Senior Physician of St. Thomas's Hospital.

MANY will refuse their assent to the leading propositions adduced by Dr. Williams, but no candid person will deny that the volume exhibits very considerable talent and originality. Though professing to consist of "Elements," we cannot recommend it to the student, for it requires some previous reading, and some practical familiarity with the diseases treated of, to enable any one to judge of its merits and to detect its faults.

After an introductory essay upon the action of poisons, (in which he adopts the opinion of the best authorities—that they are usually absorbed, and act through the medium of the blood,) the author pro-

* Cases of decided transmission through the whole length of the stethoscope are perhaps rather exceptions, independent of those where there is only a resonance under it.

* If I recur again to pectoriloquy, it is certainly not from lack of subjects calculated to illustrate the difficulties—the extreme difficulties—which are met with in the study of auscultation.

ceeds to the consideration of those diseases which he holds to be both contagious and infectious; namely, typhus, scarlatina, morbilli, variolæ, varicella, erysipelas, pertussis. In this list, however, there are more than one with regard to which it is by no means an acknowledged truth that they possess the characters in question.

First in the catalogue stands "Typhus," which, we are told, "is a continued febrile disorder having no intermissions; it runs a course of very varied length, and is both infectious and contagious." On reading this proposition, we supposed that Dr. Williams limited his application of the term typhus to certain forms of the continued fever of this country, which he regarded as unequivocally communicable from one person to another, and had thus been the case we should not probably have made any remark upon it; but on turning the page, we find (p. 27) that "there is but one simple continued fever known in this country, and that is caused by the agency of the typhoid poison." Now these two positions taken together amount to this—typhus is contagious, and there is no other fever in this country,—therefore all our fevers are contagious. This, we apprehend, is giving a universality to the principle, in which he will find very few disposed to agree with him: in fact, the doctrine seems to be assumed as an axiom, and all the illustrations alluded are intended to shew the manner and circumstances attending a pre-established fact, rather than to demonstrate the accuracy of the principle itself. No confident, indeed, is Dr. Williams in the existence of contagion as the only source of the disease, that he attributes it to this even after the interval of months from the date of exposure, rather than have recourse to any other origin. Thus, "a man slept with his father, nursed him, and lost him in typhus early in the spring of 1828. In the September following this person sickened with a most violent form of fever, and was only recovered with great difficulty. Now supposing this man to have imbibed the contagion from the only source to which he could trace it, five or six months must have elapsed from the time of his exposure to the cause till the appearance of the disease. The extreme periods, then, which the poison of typhus may lie latent, vary from a few hours to a few weeks, or perhaps a few months."

Although we have thought it proper to give the reader an idea of the extent to which Dr. Williams carries his notions on this head, as essential to a just view of his opinions, we are nevertheless far from having any intention of going into the discussion on contagion. We now proceed to the practical views of our author.

Having once affected the human body, the poison of typhus is described as "falling" sometimes upon one tissue, sometimes upon another, but more especially implicating the alimentary canal, the brain, and the lungs,—of the changes produced in which a very clear and satisfactory account is given. But even here there are some positions the accuracy of which we cannot admit: thus we are told that "it is a law that the typhoid fever does not wear itself out or die; that the patient does not become insensible to its action until it has produced the lowest state of depression consistent with human existence." Now the only idea we can attach to this is, that before a patient can recover from typhus fever, he must previously be reduced to a condition in which he is all but dead, so that the slightest imaginable increase of his depression would be fatal. But some patients pass through the fever with comparatively little debility, being scarcely confined to bed at all; while another is laid on his back for weeks, with a black tongue and a thready pulse. Are we, then, to admit that both these are equally brought to the lowest state of depression? this can scarcely be Dr. Williams' meaning, and yet if it be not, we really do not understand the expression.

The treatment is divided into curative, dietetic, and preventive. It has been attempted to arrest fever at once by cold affusion, and by the exhibition of emetics; but of neither expedient does our author entertain a favourable opinion. The assertion that "a poison circulating with the blood cannot be removed from the system by ablation of its (2) surface," conveys his estimate of the one; and with respect to the other, we are told that there seems but little ground for believing that emetics can, "under any circumstances," have the effect of stopping the disease.

Have we, then, any antidote to the poison? Bark is first discussed, and summarily dismissed, nor without sufficient reason, the mass of evidence against it being quite conclusive. Next comes

mercury, concerning which Dr. Williams expresses no more favourable opinion than this, that the evidence against it "is not so great as that against the use of bark;" but the argument on this part of the question is very inferior to that in which bark is discussed. We shall admit, however, that mercury is not a "specific" in continued fever, in order that we may arrive at the last and most novel part of the subject, namely, that in which the idea of cutting short the disease, or of finding any direct antidote, being abandoned, the author proceeds to inquire what is the best mode of treating this formidable disease?

The different authorities who have written for or against bleeding are adduced; and after a fair estimate of their statements, the conclusion is, that the evidence against bleeding outweighs that in its favour, so that, although this depletion may be occasionally useful, yet such cases constitute the exceptions, and not the rule. This brings us to the chief peculiarities in the views of our author, and which we subjoin in his own words.

"The positive rules of treatment are not to anticipate any thing in fever, but to await the occurrence of each particular symptom; and inflammation being set up, to remember that it bears a specific character, and that we might as well attempt to stop the small pox eruption as to impede its course. All, therefore, we can effect prior to the inflammation, is to remove all those causes which may irritate, and consequently predispose any organ liable to be affected; or supposing the inflammation exists, to remain satisfied with so moderating its intensity, that the life of the patient may not be endangered by this particular affection; and beyond this, medicine has at present no power, except to stimulate those secretions which are in defect, and to restrain those which are in excess.

"The attempt to cure fever by antimony, ipecacuanha, or any of the many other of the large class of diaphoretics or purgatives, and where there is no particular indication to be met, is now considered to be a useless practice, or only calculated to amuse the mind of the patient. Let us therefore, looking to the rules that have been mentioned, suppose the fever to be established, and that the poison has, or is about to set up

its great specific action on the mucous membrane of the intestinal canal; what is the mode of treatment to be adopted?

"As a general principle, there is no known symptom that marks the point at which disordered function of the mucous membrane of the intestinal canal ends, and alteration of its structure begins. It is necessary, therefore, in all cases in which the disease has existed but a few hours, to assume that inflammation of some portion of the alimentary canal does exist: an assumption which, though it may not actually be the fact, is true in forty-nine cases out of fifty. In this state of the disease, a large number of experiments has been made in St. Thomas's Hospital, to determine the most beneficial modes of treatment, and the following are the results of my experience

"In a very large majority of cases diarrhœa is the only, or the principal symptom, when the alimentary canal is inflamed. The number of stools varies from three or four to eight or ten, or even to twenty, in the twenty four hours. They are always loose, and may be indifferently green or yellow, ochre-coloured or black, and frequently contain large flakes of mucus, tinged with bile, and resembling moss-like vegetations. These stools do not furnish us with any accurate data, either as to the nature, the gravity, or the particular seat of the inflammation: for no difference has been observed in them, whether the inflammation be diffuse or follicular, or whether its seat be the colon, the cæcum, the small intestines, or the stomach. It will be evident, in such a state of things, that the exhibition of a series of doses of purgative medicines can only tend to keep up an irritation, which must greatly tend to aggravate the existing inflammation; so much so, that out of ten patients treated by purgatives by Andral, nine died. It is also certain, that even so mild a remedy as the hydragyrus creta has little power over the diarrhœa to assuage it, and perhaps none to change the character of the stools, and to render them more healthy, until the violence of the disease be past. The whole class of astringents seldom proves efficacious; opium affecting the brain, while kino, hæmatoxylum, and catechu, increase rather than soothe the inflammation. Neutral salts, which are not

purgative, as the acetate of potash, either in the state of effervescence or otherwise, are grateful to the patient, and, by tranquillizing the stomach, always give relief, and are so far beneficial; but in other respects they exercise a very trifling influence over the disease.

"Medicines, then, have little effect, either in controlling or subduing the inflammation of the intestinal canal in fever, or even in controlling the diarrhoea. It remained, therefore to try what effects an almost purely local treatment would produce, and whether, by means of soothing the intestine, we might not moderate the inflammation, and in this manner produce, both directly and indirectly, more sanatory effects. Many different plans have been tried to effect this object, but that which has been found the most successful is that of enemata, consisting of barley-water and of syrup of poppies. This plan has been tried during the last seven years in a large number of patients at St. Thomas's Hospital, and with, comparatively speaking, very favourable results. The mode of treatment is as follows:—

"Immediately on the admission of the patient, whatever may be the stage of the disease, ten grains or a scruple of rhubarb are exhibited. The object of this preliminary dose is thoroughly to empty the intestines; for notwithstanding the patient has been suffering greatly from diarrhoea, it has frequently been found, on posthumous examination, that the inflamed portion of the intestinal canal has so strongly contracted on some hard scybala, as to have retained them, and thus, contrary to all expectation, an irritating cause has existed in the intestines, which has mainly contributed to the fatal result. The bowels having been satisfactorily emptied, an enema, consisting of a pint of barley-water, together with half an ounce of syrup of poppies, has been directed to be given night and morning. This simple treatment has been continued till the patient is convalescent, and has been rarely complicated by the exhibition of any medicine whatever. Its success has been remarkable, compared with other modes of treatment, when the fever has been of any moderate degree of intensity; so much so,

that in the years immediately before the cholera, out of sixty-three cases treated in this manner, only one died. The cholera was preceded and accompanied, and followed, by a fever of great severity, and of unusual fatality, and the treatment by enemata in those years has been by no means so successful, only one being saved out of four or five. But still it has been considered, on a comparison of the deaths and recoveries under other modes of treatment, that this by enemata was on the whole the most successful."

From gr. x. to ℥j. of rhubarb in the first place, and afterwards a clyster, consisting of barley-water, with ʒss. of syrup of poppies, night and morning,—such, with "rare" exceptions, is the whole treatment of fever adopted by Dr. Williams. And here the thought is almost forced upon our minds, that the students at St. Thomas's, who a few years ago attended the joint lectures of Dr. Williams and Dr. Elliotton, must have been very singularly situated, and very thoroughly puzzled; for it is impossible to imagine any thing, even in the proverbial uncertainty of physic, more at variance than the *heroic* remedies of the one, and the *expectant* treatment of the other. But to return: the passage we have quoted above is a very remarkable one. We are told that, of 63 patients treated for typhus fever, in the manner above-described, only *one* died! This is a success almost or altogether unprecedented. Louis, Andral, and Chomel, gave 1 in 3 as the average number of deaths, and 1 in 4½ is about the least mortality described by any of them. In London, 1 in 12 has been the least mortality at the Fever Hospital, and on the great scale, it is more than 1 in 8. Seeing these results were so different from that obtained by Dr. Williams, we at first supposed that he had included in his list numerous slight febrile attacks, which scarcely run into fever, properly so called; but we found (page 79) that he makes an express distinction "between fever and those ephemeral febriculæ which simulate the first symptoms of typhus."

But again, while the usual mortality was so very small as to give only one death in 63 cases, yet in the epidemic fever which prevailed some years ago, when cholera visited this country, the

change was so great that three out of four, or four out of five, died! while it is implied, that where the practice above recommended was not adopted, the number of deaths was even greater. There is surely some typographical error in the passages we have quoted; for while we believe no other practitioner can boast so small a mortality in his cases of "typhus" as one in 63, so, few we believe, in the epidemic to which Dr. Williams refers, lost any thing like so many as he admits having done.

But our author, though employing enemata, as described, in the great majority of cases, points out, nevertheless, various circumstances which render them less useful, or even hurtful. Among the former is the seat of the inflammation being in the stomach or small intestines, instead of the cæcum or colon, or where the bowels are so irritable that the clysters are immediately rejected. Among the latter are those cases in which a considerable degree of meteorism is present, and also where there is hæmorrhage from the bowels. A few leeches, if much blood has not always been lost, are recommended; but, otherwise, the mineral acids, or supertartrate of potass, are to be preferred. Indeed, we may observe that the author is very chary in applying leeches: he says, "in applying leeches to the abdomen, much is at all times put to hazard."

When the head is affected, the following directions are given:—If the delirium be moderate, and unaccompanied by pain, it may be disregarded; but if the pain of the head be severe, and the conjunctiva injected, ten or twenty leeches are to be applied to the forehead and temples: if the pain be relieved, they are not to be repeated. In one form of head affection, though unaccompanied by pain, leeches are of use—namely, where the pulse is preternaturally slow, not exceeding 60, or it may be even 40, in the minute. Blisters are very "capricious," and not to be relied on. In cold applications Dr. Williams has so little faith, that he has nearly abandoned their use for several years.

When the lungs become implicated, the poison is regarded as having nearly exhausted itself. Local bleeding, by means of a few leeches or cupping, is generally sufficient to control the inflammation; but if not, a small vene-

section may be practised. Here mercury is admitted to be a useful adjuvant. A blister is also frequently of service, and it is recommended to dress it with a common linseed poultice. "In the cholera years," we are told that the affection of the lungs was among the earliest symptoms, and that depletion was exceedingly prejudicial, the most successful treatment having consisted in the exhibition of tonics from the commencement of the attack. Among the remedies of this class Dr. Williams particularly mentions salicine, as possessing many "singular and valuable properties;" but he does not inform us what those are, farther than that it is pleasant and easily digested.

Under the head of preventive treatment, Dr. Williams remarks, that "after taking care of the patient, it is necessary to take care of ourselves,"—an observation, we need scarcely say, founded on the engrossing idea of the danger of infection, and which leads him to inquire into the different modes of averting this. The chlorides, he believes, possess no power beyond that of destroying smells. He places more confidence in an elevated temperature, and quotes the experiments of Dr. Henry,—experiments, however, we venture to say, which require to be repeated on a much larger scale, before any satisfactory inference can be drawn from them. But were it otherwise, the degree of heat required is inapplicable during the continuance of the treatment, and therefore we are left to the simple expedient of cleanliness, separation, and ventilation.

Such is a faithful and, we trust, sufficiently distinct, though necessarily very condensed, account of the views entertained by our author on the subject of fever. If his opinions should ever become generally adopted, they will constitute a new era in the treatment of that disease; but even without this, they will probably tend to render the interference of the practitioner less constant, and probably, therefore, less harassing than it usually is. There are, however, two sets of remedies frequently adopted in our hospitals in the treatment of fever, to which Dr. Williams does not, in our opinion, do justice: one is that of simple salines, and the other that of mild alterative mercurials. Of the former he says, they exercise "a very

trifling influence over the disease ;" and of the latter remedy, that its entire abandonment "would in no case lessen the chances of the patient's recovery,"—an assertion which we do not find to be borne out by any evidence adduced.

Again, with respect to the enemata, there are one or two passages which appear to us to amount to contradictions in terms. Thus, speaking of the fever of the "cholera years," we are told at page 85, "But still it has been considered, on a comparison of the deaths and recoveries under other modes of treatment, that this, by enemata, was on the whole most successful." And again, at page 91, speaking of the same epidemic, it is remarked, "Some few of these cases recovered under the treatment of enemata; but the more successful mode was, in despite of the symptoms, a tonic treatment from the commencement of the disease." Now it is just possible that Dr. Williams may allude to different classes of cases; but if so, it is not sufficiently expressed in the context; and this leads us to observe, that there is frequently a looseness, not to say inaccuracy, of language, which much diminishes the force of his composition.

But farther: it is said of enemata at page 94, "it is a mode of treatment that is applicable to every form of the disease, and should be adopted in every case, only omitting the syrup of poppies when the bowels become constipated." But we had previously been told, at page 89, that it was not applicable "in every case: thus the cases in which enemata are of no service are those in which a considerable degree of meteorism is present." Nay, further: "when considerable hæmorrhage takes place from the bowels, the tepid warmth of the enemata must of necessity be injurious, and they ought consequently to be omitted." These passages cannot, we apprehend, be reconciled.

We shall probably take another opportunity of examining Dr. Williams's opinions on the other subjects of which he treats; meantime we recommend the volume to the perusal of those who, having seen some practice, are able to form a rational estimate of its merits, without being misled by its peculiarities.

MEDICAL GAZETTE.

Saturday, December 24, 1836.

"Licet omnibus, licet etiam mihi, dignitatem Artis Medicæ tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

THE RADICAL UNIVERSITY.

THERE is, we believe, but one opinion among those not immediately connected with it, touching the merits of the new Board of Government Commissioners for the manufacture of Degrees,—namely, that it displays a most edifying illustration of the progress which has been made in the art and mystery of jobbing. This is the second "University" for which we have had to thank the same parties; and they have at least displayed some ingenuity in contriving another institution as unlike as was the first to those seminaries which have hitherto borne that respected name.

We object to the principles on which the new establishment is founded, and to the persons by whose instrumentality it is to be attempted to carry those principles into operation.

Universities, like most other public bodies, may ere now have had more or less of a political character, derived from the opinions of their members, and from the circumstances of the times; and no doubt statesmen have heretofore endeavoured, by various indirect means, to win their support or to neutralize their opposition. Oxford and Cambridge have thus had the reputation of being the one a Tory and the other a Whig establishment; but to whichever party they inclined, their bias was the result of opinion, and their's were the politics of free men. But, as Lord John Russell has informed us, the intellectual darkness of former times has given place to the bolder and more enlightened policy of

the present era. It was reserved for the nineteenth century to dash aside all ancient prejudices, and in the foundation of a RADICAL UNIVERSITY, openly to subjugate literature and science to the minister of the day. Every rule and regulation regarding courses of education, the examinations for degrees, the mode of granting the same, the selection of the schools to be attended, and, in fact, "touching all other matters whatsoever," must be submitted to, and receive the assent of, the Secretary for the Home Department, before they can be acted upon. The so-called "Senators" are mere tools in the hands of their masters in Downing-street; they have power to do nothing whatever of themselves,—no, not so much as to purchase red tape enough to tie up the orders transmitted to them.

An extraneous jurisdiction of this nature cannot but be highly injurious to the cause of learning: even the capacious mind of "one of our principal Secretaries of State" cannot grasp all the intricacies of science; and by the new duties imposed upon him by this charter, he must be exposed (a rare occurrence, doubtless, in the present day), to legislate on matters of which he is profoundly ignorant. But, worse than this, the introduction of a discretionary power is always liable to favoritism and abuse; and the prospectus of the new University is very far from removing the apprehension of its being converted into an engine of oppression. The whole machinery is so dependent on the will of the administration, that politics cannot fail to become blended with every detail: new motives are thus called forth, and the streams of science become polluted by the agitations of party.

No jurisdiction or control over the studies of persons destined for learned professions should be conceded to any but those deeply versed in such sub-

jects; and the ulterior reference to the Home Office we regard as the most arbitrary and tyrannical principle which in these days of political freedom it has been attempted to establish. Smith, in his *Wealth of Nations*, alluding to what had then only been witnessed in a foreign country, and referring in terms of prophetic indignation to the possibility of "some minister of state" at home being presumptuous enough to hazard a similar interference, observes, "the person subject to such jurisdiction is necessarily degraded by it, and instead of being one of the most respectable, is rendered one of the meanest and most contemptible persons in society. It is by powerful protection alone that he can effectually guard himself against the bad usage to which he is at all times exposed; and this protection he is most likely to gain, not by ability or diligence in his profession, but by obsequiousness to the will of his superior, and by being ready at all times to sacrifice to that will the rights, the interest, and the honour of the body of which he is a member."

The consideration which more immediately led to the construction of a new University by the present government, was obviously the desire to establish a power to counterbalance the influence of Oxford and Cambridge; the former of which was by far too conservative, and the latter not nearly radical enough to suit its purpose. The complaints made by the Dissenters of the disabilities they laboured under, gave a plausible pretext for interference, and the advantages of conciliating so large a body of men were sufficiently obvious in a political point of view. Let us therefore consider what those disabilities are of which the Dissenters complain, and from which they demand to be relieved.

The English universities deny them access to academic honours, and thus,

it is said, obstruct their advancement in professional life: not that the degrees which they are refused would necessarily afford them access to any of the learned professions, but that they are pre-requisites, without which the doors are at once closed against them. But the extent to which this ever was the case, has been greatly, and, we fear, designedly over-rated: at all events, as we shall presently show the extent to which it now exists is so slight as to constitute little more than an imaginary grievance; and certainly is such as to render the elaborate machinery which has been constructed for the ostensible purpose of removing it perfectly ridiculous.

The first degree is that in Arts; and it is one which, *per se*, is of no value, in reference to any profession which a Dissenter can follow. Now, as we have said, in all the remonstrances on the part of the Dissenters, and in all the government measures connected with the subject, it is assumed that the preliminary distinction being denied, a barrier to their professional progress is placed at the very threshold. But the fact is, that, practically, the barrier is constantly overlept, and that without the slightest difficulty; after which the path is equally open to all. The only exception to this is in the Church, where, indeed, a degree in Arts from an English university is of value, as it affords a ground for the bishop on which to ordain the holder of it; but here it is obvious that even if he had the required diploma, no professional benefit could accrue from it to the Dissenter.

In the Law, no insuperable obstacle ever existed; and the only impediment was, that students from Oxford or Cambridge were called to the bar at the end of three years, while others, whether Dissenters or not, were only

admitted at the end of five. Even this, however, has recently been discontinued, and no impediment whatever now exists, in the Inns of Court, to the Dissenter's free and undisputed passage, without any reference to his religious opinions.

In Medicine it was different; and those who have attended to the subject are aware, that here by far the strongest case existed; as was proved both by the evidence given before Mr. Warburton's Committee, and as was set forth in various petitions presented to both houses of Parliament. In fact, it is our deliberate opinion, that the only real grievance which could be established, was with reference to the medical profession. No one was admitted to be a Fellow of the College of Physicians save by special grace, and consequently no one could calculate on attaining the highest rank in his profession unless he had an English degree; and this, Dissenters, of course, could not obtain. It is not true that the College of Physicians ever refused to admit them as Licentiates, or threw any obstacle in the way of their practice; but we admit, and have often formerly complained, that the disability was, notwithstanding, of a very formidable and oppressive nature. We have said that we *complained* of the English graduate receiving of right what others only obtained by favour; but we do not continue to complain of that which does not continue to exist—we do not, like his Majesty's Ministers, employ our artillery to break down barriers which have already been freely thrown open. The English graduate no longer has any advantage in this respect over his dissenting neighbour—all are equally required to have passed through a prescribed course of study, but without any restriction as to where this may have been carried on,

—and all are equally admissible to examination for the diploma, with or without any previous University degree. By the new statutes of the College of Physicians, all are placed on precisely the same footing, without prejudice and without favour.

Now this important measure of medical reform had been for a considerable time in agitation, and its earlier enactment was only delayed by the opposition of some physicians of the old school, since deceased. The fact of it having been finally accomplished early in the present year, was made known to Mr. Spring Rice long before he had organized the new institution which had been intrusted to his parentage; and we have no doubt that, if any communication had been made to the College of Physicians, the whole affair might have been arranged to the satisfaction of all parties. But this does not appear to have been the object; that gentleman talked with individuals, but never communicated with the Body. Nothing would have been simpler than either to have conferred on the College of Physicians the privilege of giving the degree of M.D., under certain restrictions, or to have appointed a Board to act in conjunction with them; by which all the rivalry and scandal which must now ensue would have been avoided.

But there was a political purpose to be served, and a *coup d'état* put in execution, that the learned professions might, if possible, be brought under the control of the Minister, and that the Dissenters might receive at his hands the boon—though an inferior one—of degrees in physic which confer no right to practice! We beg leave to ask Lord John Russell what he is to do for his physicians when he has made them. Will he candidly tell them that they may not practice on the strength of his diploma; or will the Secretary for the Home De-

partment connive at the violation of the law? Here is the dilemma: without an act of Parliament, annulling that which already exists, the graduates of the new University must still come before the College of Physicians—or practise illegally. Now although individuals occasionally do this, it remains to be seen whether a Government will be bold enough openly and professedly to countenance and protect an infringement of the statute. But if their graduates are obliged to appear before the College in Pall Mall, then what becomes of the University? — for besides this admission of its inferior authority, the degree is no passport to a license without the prescribed education having been gone through; and if this has been done, then no degree is required. In either case the diploma of the Radical University, so far as regards medicine will be useless; nor can this difficulty be got over in any other way than by procuring an act of Parliament,—which, as the House of Peers is not yet extinguished, my Lord John knows, by experience, is more easily said than done.

When from the principles of the new institution we turn to the *men* by whom they are to be carried into effect, we find some names highly distinguished in general science, which have most palpably been introduced to float the dead weight of the medical department. When we say of the physicians, that, with some exceptions, they are *respectable* * men, we use the most complimentary epithet which, without being ironical, it is possible for any one to bestow upon them; but our limits will not allow us to enter at present on their individual and pro-

* As the same expression has been applied to them by a correspondent in the *Times*, we beg to say that we did not borrow the epithet of him, not having seen his letter till this was passing the press. The coincidence tends to show the applicability of the term; but as to the rest, there is much in which we differ from M.D.—ED. GAZ.

merits. There is one point, however, to which we would briefly allude, because it has been brought before the public through the medium of two letters in the *Times*. It is implied, if not asserted, by the writers in question, that the government were fain to take what physicians and surgeons they did—because better men refused. This is true, but it is not the whole truth. Cooper, Brodie, Chambers, Holland, and others, were applied to, not, however, to construct,—but to concur; not to organize the medical portion of the new institution, (which, being all Whigs, it might be supposed they would have done on sufficiently liberal principles,) but by their rank and weight in the profession, to give influence and authority to plans previously laid down by others. They were asked to countenance principles of which they disapproved, and to become the colleagues of men already appointed, and with whom they thought it no honour to be associated. Therefore—and not from “being already connected with other Colleges,” as has been asserted—did they, after repeated attempts at conciliation, decline the overtures which were made to them.

As it is, we trust that when the subject of this same charter comes before the House, and the proposal of placing all professional education under the control of the Minister is discussed, there will not be wanting some to repeat the words of Milton, addressed to the government on a somewhat similar occasion—“Truth and understanding are not such wares as to be monopolized and traded in by tickets, and statutes, and standards: we must not think to make a staple commodity of all the knowledge in the land, and to mark and license it like our broadcloth and our woolpacks *.”

* Milton's *Areopagitica*.

CROWDING AT OPERATIONS.

WE insert, in another part of the present number, some communications respecting the late disturbance at the operating theatre of St. Thomas's Hospital. As the case is to be tried at the Sessions, we abstain from making any remarks applicable to it in particular; but we take this opportunity of insisting upon the very great inconvenience which results from the admission of too many persons into the area of the operating theatres at our hospitals. It is quite obvious that half a dozen heads close to the patient, prevent ten times that number of persons, placed at a proper distance, from seeing at all; and it has long been a complaint among students generally, from whom we have often received letters upon the subject, that they are thus frequently prevented from getting even a glimpse of what is going on. At some of the hospitals, efforts have recently been made to abate this nuisance, and we earnestly hope that the present unfortunate occurrence will at least have the advantage of leading to a complete reformation. It is impossible to do justice to the great body of the students, to the patient, or the operating surgeon, unless the rule be rigidly adopted of excluding from the area every individual except the operator and the patient, and those immediately required for their assistance.

THE NEW PHARMACOPŒIA.

THIS long-looked-for volume has at length made its appearance. It is very different from its predecessor, being no mere reprint, but a complete remodelling; presenting a great number of new articles of materia medica, various new pharmaceutical processes, and a very extensive change of nomenclature. So much at the first glance; but it requires to be looked through carefully, and when we have done so, we shall say more about it: mean time we insert, at page 478, a list of the names which have been changed.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

MR. C. HUTCHISON *versus* DR. JAMES JOHNSON.*To the Editor of the Medical Gazette.*

SIR,

I WAS informed by a friend, that last Saturday's *Lancet* contained the report of a speech made by Dr. James Johnson at the Royal Medical and Chirurgical Society, on the previous Tuesday evening, upon the occasion of a note of mine being read*.

The journal in question is now before me, and the speech, as reported, consists of five sentences, as follows:—

“Dr. Johnson said he had passed a long time at sea, and doubted the fact broadly stated by Mr. Hutchison. He had seen many cases of calculus in seamen. Sailors were not operated on in the ships or naval hospitals during the wars, because seamen, when known to have calculus, were invalided, and sent to our civil hospitals, and there cut. He knew a naval surgeon who was twice cut for stone, and several naval officers who were affected with calculus. He did not consider seafaring men to be more exempt than others.”

With regard to the first sentence, Dr. Johnson has a right to doubt what any man says; and though my opinions are supported by the most convincing official documents from all the civil sea-port hospitals in the United Kingdom, as well as those of the Royal Naval Hospitals, yet still, I say, he has a right to doubt.

I shall be extremely obliged to Dr. Johnson if he will have the kindness to point out the names of the hospitals and ships in which he has seen so many cases of calculus in seamen, for with such information I can test the correctness of his observations by a reference to the hospital and ships' books at the Admiralty.

The next sentence is so severe a libel on the naval hospital surgeons since the year 1800,—from which period my observations and calculations on the subject of calculous disorders commenced, and only about a year and a half after

Dr. Johnson entered the naval service,—that I hardly know in what terms to designate the assertion. Will Dr. Johnson say that any man was ever invalided* from Deal Naval Hospital during the period of war, (when I was for several years surgeon to the institution), for the purpose of being sent to the Civil Hospital to undergo any operation whatever? There are now living, Dr. James Veitch, Mr. George Vance, Dr. Jait, Sir Stephen Hamnick, and some others, I believe, who were surgeons of naval hospitals in war time, and whose very names I should think are sufficient warranty to disprove the assertion.

The naval hospital surgeon alluded to by Dr. Johnson as having been cut twice for stone, was Dr. Duke, whose case, and that of every other officer or man so operated upon which I could in any instance trace, are all mentioned and honestly recorded in my previous papers.

With regard to the Doctor's fifth and last sentence, the answer is, that as it is a mere unsupported assertion, opposed to the most authentic documents, it does not require any further refutation.

If I be not very much mistaken, naval hospital surgeons, and their brethren afloat, have been among the very first to lead the way in operative surgery, and to advance the science generally, instead of sending their patients to civil hospitals. But I rather suspect that my friend Dr. Johnson, when he went to the Society on the evening in question, had but just risen from perusing Smollett's *Roderick Random*, and so had gone back in his thoughts nearly a century.

The subjoined documents will speak for themselves; but I must add, that as truth has ever been my main object in this, as in every other professional inquiry and statement, I am sure that the profession and the public will not be satisfied without some explanation from Dr. Johnson, after so groundless an assertion.—Yours, &c.

A. COPLAND HUTCHISON.

10, Queen-Street, May-Fair,

* On the Infrequency of Calculus among Seamen. See our preceding number, page 424.—*ED. GAZ.*

* No officer or man can be permitted to leave the service on account of ill health, until he have been surveyed by the medical officers of one of the Home Naval Hospitals, two captains, and two surgeons afloat: this is what is called invaliding.

LETTER FROM DR. BAIRD.

Clarges-Street, Dec. 20, 1836.

Sir,—I have received your note of yesterday's date, desiring to know if, during the period of my service in the navy, whether as physician of a fleet, a member of the Sick and Wounded Board, and subsequently Inspector of Naval Hospitals, I ever knew an instance of an hospital surgeon in our service invaliding a patient for the purpose of being sent to a Civil Hospital to undergo an operation for the stone.

In reply, I have to inform you that no instance of the kind occurred from the date of my appointment, in 1803, up to the period of my ceasing to perform public duty; and I have further to state, that if any instance had occurred betraying such incompetency, I would have felt it an imperative duty to represent the case to the Board of Admiralty.—I am, dear sir,

Very truly yours,
A. BAIRD.

Alex. Copland Hutchison, Esq.

LETTER FROM SIR WILLIAM BURNETT.

Admiralty, Dec. 19, 1836.

Sir,—In reply to your note of this date, requesting to be informed whether I have ever known or heard of any naval hospital surgeon who invalided patients requiring operations of any kind, for the purpose of their being operated upon in civil hospitals,—I can have no hesitation in saying, that I never heard of, or was acquainted with, any such occurrence.

With respect to your second question, I naturally conclude that if such a thing had happened, the surgeon doing so would have been considered unfit for his situation; and I can only add, as respects the present time, that I should feel no hesitation in immediately recommending the removal of such a person from the office of surgeon of any of our hospitals.

I am, sir,
Your humble servant,
W. BURNETT,
Physician-General.

*Mr. Alex. Copland Hutchison,
Surgeon, R.N.*

CASE OF LITHOTOMY.

NOTE FROM MR. HILL.

To the Editor of the Medical Gazette.

SIR,

IN your last GAZETTE you mention a case of lithotomy sent by me to the Royal Me-

dical and Chirurgical Society, in which you have omitted the only circumstance which appeared to justify me in occupying the time of the Society,—I mean the total insensibility of the nervous system, with the entire loss of power of the sphincters of the rectum and bladder, produced by moving the calculus from its situation at the entrance of the bladder, some time before the operation was performed. The symptoms after the operation were, indeed, very severe and unusual, but not sufficiently so in themselves to be related to the Royal Medical and Chirurgical Society.—I am, sir,

Your obedient servant,
WM. HILL.

Wotton-under-Edge,
Dec. 20, 1836.

[We regret that there should have been any omission, but are not accountable for the abstract of his paper referred to by Mr. Hill. It was furnished to us officially from the Royal Medical and Chirurgical Society.—ED. GAZ.]

AN ADDRESS

FROM

THE FOUNDER OF THE SELF-SUPPORTING DISPENSARIES.

To the Members of the British Medical Association.

GENTLEMEN,

EVERY medical man in the kingdom will sincerely rejoice, who has heard that an Association is formed in the metropolis for the laudable purpose of increasing the usefulness, and upholding the respectability, of the profession.

And although, as I am informed, at your first meeting, the plan I have for nearly twenty years been endeavouring to carry into effect was reprobated as detrimental and pernicious to your interests, I have no doubt, even if my informant is correct, that when the Association is disabused of the prejudices that have been absurdly created against Self-supporting Dispensaries, many amongst you will bring honest minds to the investigation (which is all that the scheme requires), and will be able to appreciate the difficulties that have been surmounted, the interests reconciled, the untiring spirit shewn, and the practical good effected by the projector. During the whole of my professional life I have sacrificed my own interests to my proposed scheme of improving the medical profession, by effecting a "radical reform in its position towards the working

people of the country." Through good report and evil report I have persevered; and I can but smile at, although I regret, the misrepresentations which have already been current amongst you. I have gratefully discovered that there are a few in your great town that may be made useful allies in resisting the unjust warfare that has been carried on against the medical profession.

These acts of insult and oppression are of the same character, whether under the new Poor-law Amendment Act, or the darker doings of overseers in irresponsible vestries.

It is the dealing in human life on the principle of *contract*, that is the evil; and no amount or mode of fixed salary can make it endurable to Christians.

The lovers of their neighbours will not be satisfied till every poor person, and every pauper, can choose for himself his own medical attendant.

But the authorities—whether commissioners, guardians, or overseers—whether the abettors of, or even dealers in quackery—are only external causes of injury and degradation to medicine as a science.

The internal are the most injurious,—that host of illegitimates, who, paid for exercising one-part skill and three-parts trade, find it difficult to take up a higher station. The craft is their status, and they are naturally prone to mystify and misrepresent every attempt to liberate their dens of drugs, dregs, and darkness, from the thick clay with which they are covered.

We have, indeed, another internal enemy—to which I will not at present particularly allude, as I am unwilling to open a wider field for discussion in my first letter than necessary—but which the "British" and "Provincial" will unite in abating as a common nuisance, as soon as they are sufficiently organized to give weight to their growing powers, and improving influences.

Our noble art, by means of its united brethren, of which the "Provincial" is the first-born, is destined to establish, through the best affections of mankind, lessons of the truest wisdom.

The science which in practical usefulness excels all others, must no longer be separated from that benevolence in the body politic, which can best make it valuable.

Schools and mechanics' institutions have extended the dominion of knowledge; "self-supporting dispensaries," "medical associations," and an elective "medical board," are now required to extend the dominion of real charity.

Beggar making, like pauper making, is

an offspring of mammon, and not of charity. Let us, who know more of the nature of man than guardians, masters, or legislators, teach the world a useful lesson.

I am thankful, (as Dr. Webster, your chairman, stated,) that I have been so instrumental in bringing you together; rest assured, gentlemen, that no future efforts on my part shall be wanting to keep you at your posts, and stimulate you to increased exertions. It is a noble cause; and if we pursue a straight-forward and favourable course, all the world will be with us; do not despair. The same foreseeing and quiet faculty of combination that has so moulded events as to cause your assemblage, can direct your movements as may best suit its own purposes; travel with me, and the good is accomplished; resist me, and the glory of success will be altogether my own.

I find by the published Report, that on the cloth being withdrawn, Dr. Webster, in a speech which appears to me full of good humour and good sense, drank the toast of the evening, "Prosperity and unanimity to the general practitioners of medicine throughout the universe." Amen, and amen, is responded from land's end to land's end.

When I admit that your chairman's speech was full of good sense, you must permit me to change one word of it only, for without that change, as you yourselves shall decide, it was a sort of kaleidoscope of sentiments without object or meaning.

The chairman is reported to have said, "I wish now to mention what I consider in medical language to be the proximate causes of the meeting. I will not conceal from view the recent and still continued attempts to inflict on the profession a host of evils in the shape of 'Self-supporting Dispensaries.'" I am convinced that the Doctor must have meant to say *cure*, instead of *inflict*. Every paragraph he utters afterwards confirms this amended reading. "It is not the object of these societies (or institutions) to institute a monopoly; they are intended to promote fair and honourable (competition between institutions) conduct among the the practitioners at large towards each other; to encourage among them (in each concentrated locality) the exercise of harmony and good will; to diffuse medical information; to insist upon the rights vested in its members by the law of the land; to suppress illegal practitioners, and thereby protect the real interests of the public, &c.; in few words, to render the profession within the sphere prescribed, honourable, useful, and respectable."

These, gentlemen, are the sentiments I have so often for eighteen years reiterated as the probable fruit of Self-supporting Dispensaries, when comparatively disregarded and unknown, that I cannot but hear them quoted in the manifesto of the British Association, with feelings of complacency and good will, that is undisturbed, though my health, and success to my views, was not the distinguishing toast of the evening.

I must copy a few more observations from the chairman's address: he is very wrathful with the Commissioners, and the Penny Clubs. Before I repeat his remarks on this head, I should like to be told what have "Poor-law Commissioners" to do with affairs that do not belong to them. The Foreign Office would be as much in place, giving directions on the parish constabulary, as the Poor-law Commissioners have been in their interfering in this matter at all. Dr. Webster says, "I shall not shrink from declaring what I feel to be the truth, that nothing has occurred for a century past which has so much tended to degrade and lower general practitioners, not only in the eyes of the public, but our own eyes also, as the introduction of these Penny Clubs." I must here silence the "cheering and immense applause" that followed, by observing, that there have been other causes much worse than Penny Clubs—"farming the sick poor of parishes," and submitting to have (Oh, for the moral cowardice of London practitioners!) reports of medical proceedings inserted in the *Lancet*. These are standing libels on the profession, which have vilified and degraded it beyond all others combined.

But to return. "We are to be put up to Dutch auction—not to the highest, but the lowest bidder; we are to be pitted, the man of little experience against him of the most extensive observation, and to be forced to perform the anxious and laborious duties of our profession for an utterly contemptible pittance."

This is perfectly true. I have enlarged on the same facts for the last twenty years, and Lord John Russell presented a petition for me to the House of Commons, on the same subject, in 1826.

I have also endeavoured to remedy the evil by suggesting a judicious system of "co-operation" amongst medical men themselves, and not the "competition" which the Penny Clubs establish and perpetuate. I hope, for the sake of consistency, that none of the gentlemen who cheered the chairman's observations on the Penny Clubs, or four shillings and fourpence annual payment, were surgeons to

clubs allowing them considerably less per annum for each person?

I am not friendly to Penny Clubs—but that I foresee they must merge in Dispensaries. But to return to the chairman. He says, "Need I mention another grievance—that of quackery? This is an evil which truly preys upon the vitals of the public, and weighs down our profession, spreading over the land and assuming innumerable shapes."

"Another, and one of the greatest evils from which our body suffers, is the existence of what may be called prescribing or dispensing chemists; men who, without a particle of medical or scientific knowledge, are becoming the general practitioners in all minor ailments," &c.

They are decreasing, Dr. Webster, in all those places where there is a "Self-supporting Dispensary" established.

"I know of no country where our system of unlicensed practice exists, and I am satisfied, that, if we act with unanimity, it cannot continue in this country. Let the duties of chemists be properly regulated, and not be allowed to interfere with those of the regular practitioners."

"Another evil,"—I entreat attention to this last extract, because Self-supporting Dispensaries progressively secure the only remedy—that is, a payment for time and skill, instead of drugs:—

"Another evil is the mode of paying general practitioners; a mode which unfortunately leads to unjust suspicions of his integrity, and is often very galling to an honourable-minded man."

The following letter from a gentleman who is a stranger to me, so admirably illustrates the practical good sense of the chairman's speech, that I must trespass on your patience for its insertion. It proves that Penny Clubs, or "Self-supporting Dispensaries," are the only cure for the host of evils of which he complains. It is so satisfactory, that I expect to have, on some early occasion, your countenance, favour, and even personal protection, when I shall next visit town, in the hope of establishing "Self-supporting Dispensaries" through the length and breadth of the land.

A scheme for this purpose I intend shortly to submit, through the pages of the *MEDICAL GAZETTE*, to the members of the "British" and "Provincial Medical Association;" as I learn there are not a few who are sufficiently philanthropic and patriotic to take up the matter in good earnest.

In the course of time, from them a "Medical Board" must be elected, for regulating and bringing into order and sys-

tem our present chaos of medical economy. The outline of that scheme shall be the subject of my next communication.

I have the honour to remain, gentlemen,
Your obedient servant,

HENRY LILLEY SMITH.

Southam, Dec. 4, 1836.

P.S. There is a letter in the *Lancet*, to your Association, signed H. S. : be pleased to observe, I am not the author.

The following letter is from a gentleman, who is personally unknown to me, and of whom I made some inquiries, which will be perfectly understood by the answers.

Dear Sir,—I have much pleasure in replying to your letter respecting our medical institution, and have given it my best attention, in hopes of being able to answer your several queries satisfactorily : at the same time allow me to say, it was based upon the principles you have so fully laid down.

With respect to your first query, I really think that not more than one in ten of the free members have been accustomed to seek medical advice on their own responsibility ; and of that number, perhaps one-fourth made no payment whatever ; the others after an indefinite period of from six months to four or five years.

That the sale of quack medicines is lessened, I have not the least doubt, since the establishment of our institution ; but this must, of course, depend in a great measure on the attention which the medical men are disposed to pay to such complaints as those medicines are generally sought for. The opportunity the members have, also, of changing their medical attendant after a given time, should they not experience the relief which they had anticipated, will, I think, do much to lessen that evil.

An institution of this description necessarily brings medical men into each others' society, to suggest ideas for the good of all, as well as for the well-working of the institution itself. This naturally tends to engender a better feeling ; and I am convinced that the little jealousies which arise, and which are perhaps increased to ill will, more frequently takes place from a want of knowing each other than from any other cause ; and I have no hesitation in saying, that a much better feeling does exist in this town among the medical men than before the formation of the institution.

I have just seen the rate of payments proposed to be adopted by the institution at Stratford. I very much fear they are too high, particularly for an agricultural district. I think they should not be much,

if anything, higher than ours are, otherwise many of the most deserving of the labourers will not be able to avail themselves of it, particularly those with large families ; but if the payments are kept to our limits, the numbers will make up for the smallness of the sum. I am sure ours would never have reached half the number it does at present, with such a scale. That medical men, in general, will not expect that an institution of this kind is to remunerate in the manner they ought to be remunerated, I am well convinced ; but it will do more than they will be at first disposed to admit ; and where is the man in practice who is not always working without even the shadow of remuneration. This should not be forgotten, nor the pleasure of doing so much good on such a sure foundation, independent of what ought to be our first motive—that of having the approbation of the Supreme Being for such good intentions. It is also desirable to keep within a certain distance of the town, if possible five miles, otherwise the labour is too great, particularly if the general confidence is not very equally balanced between the parties.

Should you think these observations can be of any service, you are at perfect liberty to make use of them in any way you may think best.

Allow me to subscribe myself,

Yours, &c. &c.

THOMAS TAYLOR.

Cricklade, Aug. 30, 1836.

REMARKS

ON THE

PRESENT STATE OF THE IRISH MEDICAL CHARITIES ;

PARTICULARLY IN THE SOUTHERN PROVINCES.

To the Editor of the Medical Gazette.

SIR,

IN my former letter I presented to the readers of your excellent journal an account of the position which the professional men who preside over our medical charities occupy, with respect to the applicants for relief. I dealt (but mercifully) with their varied pursuits, and gave a brief sketch of the insufficiency and inefficacy of that professional assistance which the poor must avail themselves of, and at so considerable an expense. Well and truly might I exclaim (to which exclama-

tion I am confident every rational and thinking member of society will respond), "Charity, O charity! many, gross, and glaring, are the abuses which exist, and publicly injurious are the delinquencies which are perpetrated, under thy hallowed name!" Paradoxical as it may appear, I could, without fear of contradiction, declare the Irish Dispensaries, under existing regulations, a disgrace to any civilized community, and a convincing proof that, by artful and designing persons, who have the unblushing hardihood to advance charity as their watchword, the design of those institutions may be so metamorphosed as to become a burlesque on common sense. However, it would not display much profundity of wisdom to soliloquize over the degraded state of establishments which never enjoyed an exalted position, or to regret the mean and lowly estimate of professional character of gentlemen who appear so perfectly indifferent about their reputation: would it not be more philosophical to endeavour if possible to effect the rescue of the Irish medical charities from their original and present chaotic state, and remodel the mode of getting up such institutions, by establishing a system that would abolish many abuses in their very formation, and disarm them of those powers which in their subsequent vicious government are pregnant with so great a mass of misery? Much of the manœuvring and finesse practised in the getting up of dispensaries, is already known to your numerous readers; even so, I cannot permit this opportunity to pass without recording as an exemplification a case from real life. A son, a son-in-law, or a brother, after a preparatory medical education, incapable of securing an independence by an honourable competition with his professional brethren, beneath the scrutiny of a discerning public, becomes an incumbrance, each individual to his respective family; the aggrieved party, smarting under so great an annoyance, or the aggrieving feeling his situation rather irksome, mutually coalesce in endeavouring to secure some provision which will place the dependant beyond the reach of public patronage; the necessity for a local Dispensary in some district is immediately suggested—a necessity which never had an existence but in the inventive imaginations of the parties reciprocally anxious to get rid of what each conceives an evil, the interests of the poor being set forth as a mere subterfuge to justify so outrageous, so barefaced, a proceeding before a few gentlemen, who never deign to cast away a thought on the subject, being already fully convinced from repeated examples, that bene-

volent intentions towards the afflicted form the least item in the proceeding, being viewed as a matter of no consideration whatever, when brought in competition with the interests of the medical practitioner. If direct interest cannot be commanded, which is seldom the case, it is solicited indirectly; in either instance, the support and patronage of a few influential persons (be they of high or low degree) in the locality are procured: under this sanction, a business previously decided on is easily arranged, a few subscribers enrolled, many of them nominally, and just enough to vindicate their soliciting a presentment from the grand jury. Having so far prosperously progressed, the day for the nomination and appointment of a medical attendant to the charity is advertised; a something farcical, in common parlance called an election, is gone through, and the zealous candidate for dispensary honours is, in accordance with preconcerted measures, duly elected. Should an anxious desire to anticipate the possession of the proffered prize induce a meritorious candidate to endeavour to divide the interest, and advance his claim to the eleemosynary sinecure established by a party; under such circumstances, to provide against the event of success being doubtful, a ruse is practised; a number of frieze-coated electors, levied for the occasion, are brought to the poll, previously supplied with a guinea each by the friends of the opponent; furnished with money, and armed with their shillelahs—the usual emblems of their prowess—they are quite indifferent as to whether they are to annihilate the pretensions or the existence of the rival aspirant; and if a choice were afforded, my unbiassed opinion is, the predilection for the latter would decidedly predominate. After so meritorious and successful a manœuvre, a separation of the frieze-clad reserve could not take place without the celebration with more than ordinary hilarity of so great an achievement, and a scene that at this stage of the proceeding ended in violation of their taste and ideas, without a general rencontre, could not be allowed to pass away without an adjournment to some neighbouring pot-house, where they regale themselves with a long and deep drink to his honour or his reverence (being both used as synonymous appellatives) to commemorate the important triumph; and before the spirit should evaporate they consider the present a most convenient opportunity to arrange some ancient and hereditary disputes between the members of rival clans, when after numerous hostile demonstrations and consequent parlies, a general action eventually ensues, ending as usual,

in the extensive laceration of scalps, a wanton demolition of teeth, and after sundry other injuries are inflicted, a truce is agreed on, and they withdraw from the field of action; thus speedily affording a convenient opportunity for a practical display of the skill of the newly installed dispensary tyro; a demoralizing exhibition on the first establishing a medical charity, and an ominous introduction to so important a functionary. Many memorable instances of the success of this manoeuvre have occurred: on a late occasion, when a dispensary was being established for the especial provision of a young friend, another candidate started, was very unsuccessful in his canvas, a sweeping majority being against him: the case was an extreme one in the most literal acceptation; a friend stepped forward, supplied the necessary funds, and a number of electors created for the occasion, who never subscribed afterwards, presented themselves unexpectedly, and voted in the opposition candidate, much to the annoyance and discomfiture of the gentleman for whose accommodation the medical charity was being founded. Such subscriptions cease after the first year. Many of the subscribers, disgusted with the operations of the charity, withdraw; some continue, fancying it the cheaper way to have their domestics, horses, and dogs, physicked: others, through a more charitable motive, labouring under the delusion of rendering through the institution some relief and comfort to invalided paupers, but negligent unconcernedness being the estate of all, the professional gourmand is allowed to devour both subscriptions and grand jury grant, giving the hapless poor out of the capture, under the semblance of doing something, a little treacle or vinegar, a solution of Glauber salt, or some rancid castor oil; it being a matter of no consequence to the suffering community, if in addition he devoured those also as condiments to the manna. However, these good things have had their day; abuses, gross abuses, may grow and flourish luxuriantly for a season, until they savour too powerfully of the rankness of that soil in which they vegetate: establishments may be so metamorphosed into engines of destruction, that their very existence becomes a harlequinade on public decency. Could, I would ask, such a state of medical institutions or medical science be credited, were it not advanced on indisputable authority?—could it be conceived that the lives of the applicants in extensive districts are trifled with by the administration of a little treacle as a universal panacea, and that large sums are advanced by subscribers, and from the

county treasury, to support so outrageous a humbug and imposition? But the satisfying truth is too apparent, that such abuses at present exist. St. John Lee was held up to public censure, prosecuted, and punished; Morison's disciples are undergoing similar odium, are criminally sued, and forced to suffer penal retribution, each and all most deservedly; and in some corner of neglected Ireland, with her many advantages—as it were, under the rose—we daily witness treatment less founded in reason, and much more preposterous, than that practised by those redoubted charlatans—treatment pursued by gentlemen who are in some measure provided for by the law of the land, and who are bold enough to declare, that the whole of medical and surgical literature may be comprised in a volume equal in size to a diamond edition of Lord Byron's *Child Harold*.

Prospects in the dim vista are at last commencing to brighten, if we are justified in indulging so pleasing an anticipation from a ray of reform which has just beamed upon us in the shape of a clause in a late legislative enactment; at least the spirit which it has evinced clearly proves that the Irish medical charities are not altogether overlooked or forgotten, but that some of their malpractices are known in higher quarters, and duly estimated. It is not to be expected that the readers of your able journal can be acquainted with acts of Parliament directed to advance the interests of Ireland. I take the liberty, then, of directing their attention to the Irish Grand Jury Act, which was passed into a law during the last session, and which, in its 81st clause, provides, "That no presentment can be made for any dispensary, in case it shall appear that the salary of the medical attendant during the last year amounted to one-half of the sum which the subscriptions, donations, and the sums presented for, would amount to." If every measure that is introduced savouring of novelty, and every innovation on accustomed usages, however salutary, will meet with opposition as a necessary consequence, how much more strenuous must the resistance be, when the pockets of those defaulters against whom this shaft is aimed are trespassed on. As might be expected, this very wholesome measure, on its introduction to this country, created a great sensation amongst the physicians and surgeons of dispensaries. The legislators and the government were denounced, and appearances are wearing a formidable aspect. Trifling incidents have often given rise to serious results, which the British government, from dearly-purchased experience,

fully convinced of; and the abet-
disorder have laid it down as an
shed rule, to raise an outcry against
nactment that interferes with their

The grievance, as they have been

the originators of the hue and cry,
er willing to permit them to repose
r accustomed obscurity.

medical club, under the specious appel-
of the Western Medical Society, was
it into existence,—I cannot be par-
as to the exact day, not being at
ouchment; and as an application
venerable sire might awaken unhap-
pinnescences, as the offspring is occa-
y looked on rather unworthily by
rent, more especially when expecta-
re grievously disappointed, and no
whatever can attach itself to the
y; and as an application to its god-
the jovial secretary, to learn the
day of the month, or week, or hour,
be attended with tedious delay, as
y not be very communicative under
ig circumstances, and would view
quiry with suspicion,—it is suffi-
or my present purpose that such a
as been established these seven years
purpose of indulging in and enjoy-
e festivities of the season, and ban-
g together on appointed days. But
unprecedented and unaccountable
migration has taken place; it has
ly bounced from its infancy to its
, without going through the usual
pmental processes or gradations in-
to life, or even deigning to pass
h the climacterics between these two
es of animal existence. Extraor-
as it may appear, I can positively

for the authenticity of the fact,
g the explanation of this (to me) un-
eled violation of the laws of nature,
sagacity of some more profound
ologist. I can only throw out, as
speculative suggestions, the effects
te dampness of our climate is said
duce on the constitutions of many,
ie influence the planetary system is
o exercise over sublunary mortals,
er loaded with hoary honours. And
s unenvied state of premature decay
mental imbecility have those anti-
onists set up Bacchus as their tute-
leity; and during one of their sa-
al orgies to this divinity, drivelled
a requisition, announcing the neces-
or convening a public meeting, in ac-
ce with a requisition published in
ily papers. A number of the medi-
tendants of dispensaries, alive to
own pecuniary interests, assembled,

each individual vieing with his brother
practitioner in ardent desire to inflict sum-
mary vengeance on the presumptuous in-
truders on their vested rights.

After the usual preliminaries were gone
through, an endeavour was made to depict
the extremity of their distress; but their
spouting was of that order that the re-
porter, through compassionate feeling for
the members of a learned profession, from
whom something chaste, if not very elo-
quent, should be expected, refrained from
publishing their ridiculous rhodomontades.
Four resolutions were proposed, and for-
mally seconded. The first expressive of
the injustice of the concluding proviso of
the 81st clause of the New Grand Jury
Bill for Ireland, which proviso I have be-
fore alluded to. The second embodies the
vague and defective state of the laws hi-
therto passed for the regulation of the me-
dical charities in Ireland; that the claims
of the objects of charity have not been
sufficiently protected; and that the adop-
tion of such measures as may tend to the
establishment of a system more adequate
to the alleviation of the wants and mi-
series of the destitute poor, is most impe-
ratively called for. The third maintains
that a fair and competent remuneration is
a simple, just, and natural right, and as
such it is claimed in common with the
other liberal professions in this country.
The fourth demands the attention of the
profession at large, in the strongest man-
ner possible, to the absolute necessity of
union, firmness, and active co-operation.
The term injustice, in the first resolution,
flows with an unbecoming grace from the
lips of gentlemen, for a history of whose
injustice in the discharge of the most
momentous duties, I have only to refer to
the reports of the assistant medical com-
missioners, and delinquency actually cou-
pled with injustice; when we call to
mind that the performance of those duties
was left to their honour, and the dictates
of their consciences, commodities so ex-
ceedingly elastic on this occasion, as in
some other cases, that they can be stretched
with the most placid composure and self-
satisfaction, to any desired extent. As to
the second resolution, fortunate would it
have been for the public at large, and
more especially for the distressed appli-
cants at the Irish Medical Charities, had
laws long since existed sufficiently strict
to have enforced the observance of obliga-
tions which were never sincerely entered
upon, and have been so grossly violated
in most instances; laws which would have
rendered imperative the protection of the
objects of charity, whose interests from
the first foundation of these institutions,
have been considered of a mere secondary
nature. It is sufficiently evident that no

system, however valuable, can tend to the alleviation of the wants and miseries of the poor, whose direction and chief government are left to the option and caprice of persons who view their dispensary duties as a mere formal routine to save appearances, and as drawbacks on their ordinary amusements. The third resolution clearly evinces the spirit and feelings which dictated the whole procedure, a dread, in fact, of the privation of emoluments which they are enjoying at the expense of the destitute and afflicted, without discharging a single obligation, and displays the resistance to any measure, however salutary, which will be offered, should it interfere with their depositing the whole proceeds of the institution in their own exchequer. In the fourth we have an appeal to the feelings of the profession; an endeavour to enlist in their cause, union, firmness, and active co-operation; these are expressions very familiarly used, and well understood in this country to mean firm, active, and co-operative combination—an evil, misguided spirit, which too freely opposes itself to all legalised measures, and has introduced some of its most devoted partizans to very exalted, but not very honourable, elevations. A committee was formed of dispensary superintendents, and from this troubled estuary will flow the muddy inundations which threaten to deluge the Lords and Commons. On the whole, we have in this delightful morceau from the physicians and surgeons of dispensaries, an acknowledgment of error, imperfection, want of legal measures to enforce obedience, and avaricious acquisitiveness, which could not proceed from the united wisdom of any similar meeting in the universe. A letter was read from Lord Morpeth, in reply to some communication stating that the clause was introduced at the instance of Irish members of all parties. But, as if consistency was doomed never to be a virtue inherent in the bosom of an Irish senator, disclaimers to this accusation were sent by three absent members of parliament, who threw the whole onus on the House of Lords. One member condescended to attend the meeting, who, in the enjoyment of his ambitious elevation, was complaisant enough to plume himself on belonging to the medical profession, and promised, as a pacificator, to introduce a bill immediately on the meeting of parliament, to get this clause repealed, to which they (indulging in a witticism) have applied the soubriquet “obnoxious.” To be inducted a member of parliament in this distracted country, the political adventurer, in order to lay claim to public patronage and individual suffrage, has only to embark as a public brawler, make speeches about com-

munity of rights, agrarian division, and the propriety of an equal distribution of property, proving that as we are all born alike, no one had a right to have more property than his neighbour. Such being his laxity of principle, it is only equalled by his inattention to the duties imposed on him, and his faithlessness to the interests of his constituents. That such a member can have the effrontery to demand the abolition of a clause likely to introduce a salutary improvement, I feel satisfied, and even advocate the welfare and utility of the Irish medical charities under their present professional and fiscal arrangements, in the face of the adverse reports published by the assistant medical commissioners. It can scarcely appear credible that any government will, after enacting a measure, and with sufficient reason, render itself a puppet in the hands, and repeal their edict at the suggestion of, a partial body, without affording time to witness its operation. Nothing could, in my opinion, tend more powerfully to establish against themselves the charge of hasty legislation, incapacity, and inconsistency. What reasonable allegation can they advance in justification of the demand? From all the information which has been acquired at so great a labour and expense, and from written documents, it appears irrevocably established, that the Irish dispensaries do not, neither are they calculated, to advance scientific research. They are of no public utility; they are not meritorious appendages to any official functionaries; and as at present constituted, can in justice claim nothing from the government but a most sweeping and intrinsic reform: in reality, every party anxious to disown a collusion with abuses, must feel desirous to have such incumbrances erased. Even in the department of forensic medicine they seem totally inoperative.

It has been my desire to avoid encroaching unnecessarily on the pages of your very valuable journal. I shall, as briefly as possible, communicate a case, selected from numerous instances, to support the position of their inutility in the province of forensic medicine, which I have just advanced. A person received some injuries from the brutal usage of another individual, for the alleviation of which, after the customary preliminary visit of the medical superintendant of the charity to the applicant's house, he was admitted as an intern hospital patient, and treated according to the routine of the establishment. The matter afterwards became the subject of legal proceedings, and on the trial the surgeon of the hospital was called to give evidence as to the nature of the injuries, the effects that re-

om them, with other information
throw light on the case: the
the injuries could not be elicited,
the results be ascertained from
mination: all appeared wrapped
ost profound mystery: he prevari-
ed the assistant barrister who pre-
nimadverted sharply and indig-
n the professional evidence, and
considerable surprise at its utter
to assist in forwarding the inves-
of what to all appeared a very
simple case. Some other strange
features which presented them-
uring the examination, induced
iry into the treatment adopted,
er the detail of some exceedingly
measures, it appeared the remedy
chief reliance was placed, and
edy considered of most vital im-
was the suspension of a blistering
t the head of the patient's bed, as
devil to frighten away disease
uld not be comprehended. The
cene drew forth the censure of
d jury; so shameful an exposure
ce, which never had a precedent,
ly impressed the hearers with a
conviction that the practice of
men was a tissue of perfect hum-
nd thus was odium drawn not
the gentleman who flourished so
ly before a court and jury, but on
ession at large. We have heard of
nd amulets, spells or incantations,
of every description of humbug
ekery, likely to please the fancies,
ate on the credulity of the public,
treatment in an hospital in the
th century, with ample funds to
its interests in every department,
s all.

RBANCE AT ST. THOMAS'S HOSPITAL.

MEETING OF GUY'S STUDENTS.

*(From a Correspondent *.)*

Friday evening last a meeting of the
of Guy's Hospital was held, at
the Tuns Tavern, Borough, for the
of taking into consideration the
ances connected with the distur-
bat took place at the operating
of St. Thomas's Hospital, on Fri-
16th, and of adopting such mea-
should seem necessary to vindicate
es and friends from the charges

ave taken leave to condense considera-
port of our correspondent.—**L D. GAZ.**

brought against their conduct on that oc-
casion. About 150 students were present.
Mr. Blackburn was called to the chair.

The Chairman explained the object of
the meeting, and urged the importance of
proceeding steadily, and with good tem-
per, to business. He recommended, also,
that time should not be lost; and in order
to set an example of needful dispatch,
called on Mr. Tweedie to bring forward
the first resolution.

Mr. Tweedie complained in severe terms
of the conduct of the door-keepers and
others at St. Thomas's. On Friday last
two operations for lithotomy were to have
been performed at that hospital, and a
large concourse of students were collect-
ing to witness them. Several gentlemen
from Guy's, in accordance with their usual
custom, presented themselves for admis-
sion: and having upon former occasions
sustained inconvenience from the incivility
of the porters, took care to be provided
with their cards of admission. Two of
the dressers from Guy's were proceeding
to their proper seats, having shewn their
tickets, when they were rudely assaulted
by two menials stationed within the the-
atre. This sort of treatment being resisted,
a disturbance took place. The students at
the outer door, imagining that personal
violence was being inflicted on their friends
within, burst open the door, and rushed
to their rescue. Such was the ground for
an unjust charge of assault which had
been brought against the two gentlemen
already mentioned; and a third, who was
not in the hospital at the time, was
summoned for breaking down the door.
No difficulty, however, would be found in
rebutting the charge, and demonstrating
that the whole disturbance originated in
the conduct of those who had now the
audacity to add false accusations to their
gross violence. Mr. Tweedie concluded by
moving—

“That the students of Guy's Hospital
having understood that certain charges,
arising out of the recent disturbance in
the operating theatre of St. Thomas's
Hospital, are brought against Messrs.
Mosgrove, Lingwood, and Carrington,
three of their fellow students, and be-
lieving these charges to be without foun-
dation, resolve to combine for the purpose
of investigating the evidence and laying
it before a proper tribunal.” Seconded by
Mr. Tamplin, and carried unanimously.

Mr. Gaselee, in submitting to the meet-
ing the next resolution, considered this as
a question not affecting one or two pu-
pils, but the school at large; upon which
a stigma of misconduct had been levelled
by some of the officers of St. Thomas's
Hospital; for from the moment that the
pupils of St. Thomas's had been desired,

by Mr. South, to separate themselves from the pupils of Guy's, it was clear that the imputation was cast upon the whole, and the odium of misbehaviour (if any) was attempted to be removed from the shoulders of the few to be affixed to the body of the school at large. He could not help expressing his surprise also at the uncere- monious rejection which one of the ac- cused gentlemen experienced, when he afterwards went over to the steward of St. Thomas's, with an anxious desire to afford such explanation on his part as should effect an amicable and satisfactory adjustment of what had occurred. He would add, that no three gentlemen could probably have been selected from the school of Guy's Hospital, upon whom the imputation intended to be conveyed could have been framed with greater *prima facie* evidence of its untruth; for they were each distinguished in the school for his general propriety and demeanour.

Mr. Gaslee concluded by proposing the following resolution, which was also car- ried unanimously:—

“That, for the purpose mentioned in the first resolution, a Committee, consist- ing of Messrs. King, Tweedie, and Black- burn, be appointed, to collect the evidence and prepare the defence; and that all those who can furnish any information be urgently requested to place themselves immediately in connexion with this Com- mittee.”

The meeting then resolved itself into a Committee, at the chairman's suggestion. Those who had evidence to offer were to remain in the room, the rest retiring in good order and harmony; and the Com- mittee, aided by their Solicitor (Mr. Peile), were engaged up to a late hour in examining the evidence.

PROTEST OF THE ST. THOMAS'S STUDENTS.

To the Editor of the Medical Gazette.

SIR,

THE particulars of a disturbance which occurred in the operating theatre of St. Thomas's Hospital, on Friday last, have been circulated in the daily papers.

The surgical pupils of that institution have expressed to their medical teachers their indignation at the gross misconduct exhibited to strangers then present.

We are now desirous, through the me- dium of your journal, to give publicity to that declaration of our feelings, and con- vey to you, thus briefly, the expression of our abhorrence of such proceedings, and our conviction that they are alike discredi- table to the character of the individuals concerned, and derogatory to that of a liberal profession.—We are, sir,

Your obedient servants.

[Between fifty and sixty signatures.]

PROCEEDINGS AT UNION HALL.

On Wednesday, the circumstances of the disturbance were brought under the cognizance of the magistrates of Union Hall Police-Office, when, charge and counter charge being heard, the affair ter- minated for the present by the three students of Guy's, Messrs. Lingwood, Carrington, and Mosgrove, being held to bail to answer a prosecution by indict- ment at the ensuing Quarter Sessions. Mr. Jeremy considered some points in- volved in the case to be of too intricate a nature to allow him to dispose of the mat- ter summarily.

LIST OF MEDICINES,

THE NAMES OF WHICH ARE CHANGED IN THE NEW PHARMACOPŒIA.

NOMINA PRIORA.

Acidum aceticum dilutum.
 ——— muriaticum.

 Unguentum elemi.
 — hydrargyri ammonio-chloridi.

OUTRAGE AT APOTHECARIES' HALL.

WE regret very much to state, that an outrage of the most violent and disgraceful nature took place on Thursday evening, at Apothecaries' Hall. A gentleman had been examined; and having answered the questions put to him in a manner which induced the Court to decline giving him a license, he took from his pocket one of those instruments loaded with lead which are called "life preservers," and attacked those present in the most violent manner. Mr. Hardy was knocked down and dangerously wounded, by a blow on the head; Mr. Este and Mr. Merriman severely wounded on the face and temple. Mr. Taggart also received a slight blow on the head. The assailant was then mastered, and given in charge to the police. He was yesterday examined, and committed to stand his trial. It does not appear that either insanity or intoxication can be pleaded in excuse of this most outrageous proceeding.

There were above twenty students waiting to be examined: they conducted themselves in the most becoming manner, and the examinations were postponed till last night.

A writer, only in our last number, asked for the fruits of the "Crown and Anchor Meeting" of last season: let him behold a specimen of the consequences of that and the other systematic attempts of our contemporary to incense the students against the Worshipful Society.

**INJURIOUS EFFECTS OF
"WAKLEY'S ACT."**

To the Editor of the Medical Gazette.

SIR,

I BEG leave to send you the following case, as another illustration of the defective working of the act lately passed for the remuneration of medical men called to attend at coroners' inquests.

On Tuesday morning last, at about two o'clock A.M., a man was found apparently dead on a wharf near the City Road. I was called to attend between four and five o'clock, and on my arrival ascertained that life was extinct. No opinion could be formed as to the cause of death; but he was known to have been intoxicated on the previous night. The body was removed to the Islington Workhouse, where a post-mortem examination was performed, and it appeared that the man had died of apoplexy, without rupture as it appeared of any considerable vessel, and probably induced by excessive drinking, as the sto-

mach contained a quantity of gin. I, of course, expected to be summoned to the inquest; but it took place without any medical evidence being required, and the jury brought in a verdict of—"Died of excessive drinking," on the evidence of two or three bargemen.

The objection to the production of medical evidence was founded on the necessity of paying the medical witness, according to the provisions of the new act. Now I need not argue for one moment on the necessity of medical evidence in cases of suspicious death; and can only declare that I am ready, gratuitously, at all times, to investigate such cases for the furtherance of the ends of justice, science, and humanity, and heartily desire to see a speedy repeal of an act which, though good in itself, thus enables the coroner to defeat these admirable purposes.

I remain, sir,
Your constant reader,
ROBERT H. SEMPLE.

LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE XIV.

Signs of Pregnancy further considered—Complications of Pregnancy—Dropsy—Ovarian tumors—Moles and hydatids—Extra-uterine Pregnancy—Cases of fallopian and interstitial pregnancy—Postmortem signs of pregnancy and conception—Corpora lutea—Medico-legal questions—Grounds on which the gravid state may be negatived—Pregnancy without consciousness, how far admissible—Prussian law—Responsibility of women in the pregnant state.

In my last lecture, I gave a summary account of the signs of uterine pregnancy, and confined myself chiefly to a notice of those which seemed more or less worthy of confidence, and most likely to serve the purpose of the medical jurist. It may be useful to recapitulate those signs: not, however, in the order in which they have already been stated, but in one suggested by a view to the requisites of practice; for it should be kept in mind, that a principal point expected to be determined by the medico-legal referee, is not only whether pregnancy exists, but *how long* it may have existed. What, then, are the signs which may be observed during the successive stages of utero-gestation?

First three months.—To say that we can have even equivocal signs of pregnancy in the living female, during the first two or three months, were almost too strong an assertion in forensic medicine. It is possible, indeed, that, in midwifery practice, an

accoucheur may assure himself, partly relying on the statement of his patient, and partly on certain doubtful appearances which acquire some value in connexion with collateral testimony, that there is reason to believe a woman pregnant, within the first few months after avowed intercourse; but no such ground of belief can be assumed by the medical jurist: he can only rely on ocular, tangible, or audible signs; and of these, perhaps, there is only one that can be available at so early a period; I allude to the marked appearance of the areola—that is, when it is marked. The sign is by no means invariably met with in pregnancy; but when it does present itself, it affords a high degree of probable evidence. Towards the end of the second month, the turgescence of the nipple, and the development of the little glandular follicles, are principally to be observed, although the characteristic change of colour is not yet very distinct. "The colour, at this period," says Dr. Montgomery, "is in general little more than a deeper shade of rose or flesh colour, slightly tinged with a yellowish or brownish hue."

The examination of the breasts, even at this early period, may exhibit more signs than might immediately be expected. The gentleman just quoted relates the case of a girl who had incurred the risk of pregnancy, but contrived to lull suspicion, for a time, by staining her linen at the usual menstrual periods. Dr. Montgomery visited her during the third month, and found the areolæ so distinct, and exhibiting their proper characters so perfectly, that he was persuaded of her pregnancy. But perceiving, moreover, that the breasts were marked with those silvery lines observable on parts previously much distended, he told her his opinion, that she was then with child, and, further, that she had certainly been so before. She was so completely taken by surprise that she confessed the fact, and added that she had suffered much from distension of the

breasts, during the pregnant state, two years previously.

Fourth and fifth months.—There is a possibility of the movement of the foetus being perceived towards the end of the fourth month. But when we recollect how many circumstances may tend to deceive us, no great expectations can be entertained on that head. If the female has a motive to feign pregnancy, she can readily puzzle her examiner by spasmodic contractions or twitches of the muscles under his hand. This sign, in fact, can only be properly observed when the woman is perfectly quiescent, or at least indifferent as to the result of the inquiry; and such is not a very likely case to occur in medico-legal practice. The stethoscope may, about this time, distinguish the placental bruit, and, according to some observers, the pulsations of the foetal heart also can be heard. If these latter indications are observable, and that satisfactorily, the point is settled. But, for reasons already stated, we must not be too sanguine in expecting, so soon, so high a degree of evidence.

The areola by this time has undergone a further degree of development, rendering those characters just now described in every way more distinct. The dark-coloured disk or circle, having a diameter of above an inch, around the nipple, and varying in the intensity of its hue, according to the complexion of the party, has nearly attained perfection; and the nipple itself, together with the integument immediately around its base, are pullulent with turgid glandular follicles. The moisture, too, of the parts is to be noticed.

Sixth month.—As the duration of pregnancy advances, the proofs accumulate. The areola, if such sign have made its appearance at all, is by this time perfect. The enlargement of the abdomen, provided it be found symmetrical, with an alteration in the navel, becomes a sign presumptive towards the fifth or sixth month. The auscultatory method of observation may now be applied with more chance of success. By the sixth month, the double pulsations of the foetus will very probably be heard, provided the child be alive, and not inopportunately located. The touch will now most likely indicate the change of form of the cervix uteri; and the *ballotement*, or passive motion of the child, may be distinctly felt. Possibly the active movement of the foetus may also be satisfactorily perceived by the application of the hand to the abdomen. Should we be fortunate enough to gather all these proofs, we may, without hesitation, pronounce positively for the pregnancy. But falling short of such an amount, or even though they be almost all absent, we had need to be guarded: we must still take care not to

negative the possibility of the pregnant state.

Last three months.—Unless there be some remarkable complications in the case, the proofs during the seventh, eighth, and ninth months, are comparatively easy. All those already mentioned, except the *ballotement*, ought to be more or less ascertainable.

I shall illustrate these remarks by narrating to you some particulars of a French report, which I find in a recent medico-legal work. These official reports, by the way, which are prepared for the tribunals in France, are, many of them, as I have already observed, well calculated to instruct. They show the order in which the several circumstances deemed most important are usually observed in practice. The person examined in this instance was a young widow, eighteen years of age. Her husband had been dead for two months, and it was said she was *enceinte*. The medical jurists, to whom the personal inspection was committed, made their external observations, of course, first, and they particularly noted the enlargement of the breasts, and the appearance of milk in them; also, the enlargement of the abdomen, and the projection of the navel. They then proceed to say,—“Having requested Madame G. to stand up, leaning against a piece of furniture, with her legs a little apart, the forefinger of the right hand was introduced into the vagina, whilst the left pressed externally on the abdomen. We found that the uterus was much augmented in volume, and that it reached as high as the navel; its neck was turned upwards and backwards; and the *ballotement* left no doubt of the presence of a moveable body in the womb. The stethoscope being applied in the space between the umbilicus and the crural arch on the left side, enabled us to hear pulsations double as quick as those which were perceptible in other parts of the abdomen. From these observations, we conclude that Madame G. is in the sixth month of pregnancy, or thereabouts.”

Other supposed signs.—In closing this account of the signs of uterine pregnancy, I ought to mention that I have omitted a multitude of others, purely because they were not suited to the purposes of the medical jurist. The state of the pulse during pregnancy, though it has the prestige of antiquity about it, being as old, indeed, as the time of Galen, need not delay us: nor should I occupy your time very profitably with an account of the blood in pregnant females. A word or two, however, may be devoted to the subject of the urine in pregnancy. Savonarola, towards the latter part of the fifteenth century, described a certain cloudiness which he said he noticed in the

urine of pregnant women; and Foderé thought the observation worthy of note, as he said he had verified its accuracy. But M. Nauché still more recently informs us, that if the urine of a pregnant woman be allowed to stand for thirty or forty hours, it deposits a white, flaky, pulverulent, grumous matter, which proves to be caseum, or the same kind of substance which is formed in the breasts during pregnancy. My able colleague, Mr. Pereira, has investigated the subject, so as in a great measure to set the question at rest. He has found "caseum or coagulated albumen" in the urine of women far advanced in pregnancy, but not invariably in that voided during the early months. He refers also to Gmelin's *Handbuch*, where it is mentioned, on the authority of Caballe, that caseum has been found in the urine of a healthy young widow; and on the authority of Wurzer, that it has been detected in the urine of a man whose breasts were previously swollen.

Complications of Pregnancy.

I have said that there may be complications of pregnancy, such as to interfere materially with our diagnosis. Some of these must be specially noticed.

Death of the fœtus.—The fœtus may be dead: how may this operate in obscuring our indications? In the first place, suppose the child to die in the second or third month, it is obvious that enlargement of the abdomen cannot be expected to be present. Nor can we, of course, appreciate several of those signs by which we should otherwise be enabled to say how far the pregnancy had advanced.

It happens not unfrequently that the embryo dies, and yet is not expelled as an abortion, but retained till the ordinary time of delivery. There is an interesting case in Dr. Gooch's book, which will at once serve to illustrate the difficulty, and to point out the conduct which it is most fitting to adopt under the circumstances. "A lady, after the usual symptoms of pregnancy for four months, had a slow hæmorrhage for many days. No ovum came away; the hæmorrhage stopped; but though her abdomen was enlarged, from that time forth it did not continue to increase. In this state, and without menstruating, she continued five months longer, when, at the end of the ninth month from her first calculation, labour pains came on and expelled a shrivelled fœtus, of the size of the third month. There can be little doubt that it had died before the hæmorrhage. The fact that her labour occurred just at the end of the ninth month, is one of the best proofs that labour commences at that time, not from distension of the uterus, but as a law of

nature. It is curious that the same process took place in her next pregnancy: the fœtus was blighted about the same period, and yet was retained during the natural length of pregnancy. In such doubtful cases the most prudent plan is to avoid giving a decisive opinion, and, if pushed hard, to state the impossibility of doing so."

Suppose we have reason to believe the female pregnant, but have our doubts as to the life of the fœtus, how may those doubts be removed? The signs by which it is commonly judged that the fœtus has died during gestation are those experienced by the mother herself. She is said to have the sensation of a weight, or of a foreign body lying loosely in the abdomen. When she rises from her chair, when she turns in bed, stoops, or in any way changes her posture, she feels the rolling about of this weight.

These sensations, however, are of no great importance to the medical jurist, and scarcely so even to the obstetrician. A nervous sensitive mother is very apt to be mistaken. She feels great uneasiness, loss of appetite, has a bad taste in the mouth, is pale, and has a livid ring round the eyes; her breasts are flaccid, the cervix uteri is relaxed, fœtid mucus tinged with blood is discharged from the vagina, and there is a distinct feeling of cold in the lower part of the vagina.

Even these signs are extremely fallacious,—the last particularly so: it cannot but be the pure effect of fancy, for the putridity affecting the fœtus should rather increase the heat above that of the surrounding parts.

Is there, then, no sign on which the medical jurist can place reliance? Fortunately the method of auscultation here comes to his aid, which enables him either to say distinctly that the child is alive, or, upon a comparison of observations, that there is a strong presumption that it is dead.

Dr. Evory Kennedy gives a case in point—peculiarly applicable to our present purpose. "It may to the medical jurist become a matter of much importance, to arrive at accurate information on the subject of the child's life or death during the progress of pregnancy. A case illustrative of this fact occurred to the author about three years since, when assistant to the Lying-in Hospital. A woman, in the seventh month of pregnancy, was sent to that institution from the police-office, to be examined whether her child was, as she asserted, killed in her womb by certain blows and other injuries inflicted upon her by a female with whom she had a scuffle. She described very accurately all the reputed proofs of the child's death as being pre-

sent. When, however, the stethoscope was applied, the foetal heart's action was distinctly audible, and our announcement of the child's being alive dissipated all her hopes of legal vengeance, as she appeared to calculate upon hanging her antagonist at least. The prisoner, who was immediately dismissed, might, in the absence of this test, have been subject to a vexatious prosecution or imprisonment; and if the child had died subsequently, its death having no connexion whatever with the assault, she might possibly have been unjustly punished."

Recollect, however, that absence of the foetal pulsation is no proof that the foetus is dead, nor is absence of the *suffle*, for the placenta may be placed so as to be difficultly heard; and even though the placental *souffle* be detected, there may still be no living foetus. So that under all the circumstances you will see how much caution is necessary.

Ovarian tumors.—There are diseases, such as enlargement of the ovary, which have sometimes led to mistakes. A careful and competent examiner, however, will not fail to detect the real state of the case: the *touch* is generally adequate to the purpose. If the enlargement of the abdomen be from an ovarian tumor, simply, the neck of the uterus is prominent and firm, unaltered, and its body unenlarged. But it may be a complicated case; there may be both ovarian tumor *and* pregnancy. The possibility of such a conjuncture must put us on our guard lest we hastily report on the presence of one state, omitting, perhaps, the more important. We shall need, in such circumstances, to put our best diagnostic tests of pregnancy in requisition.

Dropsy.—I have already alluded to the fact that pregnancy may be confounded with dropsy, and *vice versa*. Drelincourt confesses that he mistook dropsy for pregnancy in the case of an unmarried woman; Salzmann tells us that he pronounced a pregnant woman to be merely dropsical; and Zimmermann relates that he was deceived in a case of pregnancy, considering it as tympanites. Dangerous errors are also on record of pregnant women having been tapped, the operators not knowing the risk they ran of wounding the uterus, and destroying both mother and child.

In distinguishing dropsy from pregnancy, a careful examiner will observe the superficial fluctuation—the diffused swelling of the abdomen, while the enlargement from a gravid uterus is generally circumscribed—and, above all, the absence of the characteristic signs of the pregnant state. When the disease, however, is complicated with dropsy, as it frequently is, we must be doubly cautious. Perhaps it would be a good rule, as well

in ordinary as in medico-legal practice, always to suspect pregnancy where ascites may be present in the married woman; and it might have prevented some serious mistakes, if the possibility of such a combination, in all females of a child-bearing age, had been, in certain instances, called to mind. Encysted dropsy is still more likely to simulate pregnancy, especially when attended with amenorrhoea, and the cyst occupies the lower fore-part of the abdomen. But should there really be no pregnancy, the uterus will be found empty, and all the chief signs of the gravid state will be absent.

Distensions of the uterus.—But sometimes the complication is within the womb, while there may or may not be a foetus present: there may be air, water, moles, or hydatids. Tympanites of the uterus—*Phymetra*—a malady in which the womb generates gases, which distend its cavity, and after a time are expelled,—is rather rare; and perhaps when air is formed in the organ, it is generally only contained in it for a very short time, when it deserves rather to be called *flatus* of the uterus. Dr. Gooch knew a lady who had this affection: air was expelled from the uterus with a noise many times a day. It was doubted whether it really came from the uterus; but the fact of her not being subject to the infirmity any longer the moment she became pregnant, seemed to put the matter beyond a question. Cases of this kind are said not to be rare. Dropsy of the uterus—*Hydrometra*—is not a common complaint, yet it may occur either simply or as a complication of pregnancy. J. P. Frank, in his excellent work *De Morbis curandis*, tells us of a German Princess, of a certain age, who was pronounced pregnant by her medical attendants: she, however, discharged a large quantity of water, and the uterus resumed its natural state. Not long after, the same symptoms appeared, and the same result was expected, when, to the confusion of her medical men, she gave birth to a living infant.

Moles and hydatids.—Moles and hydatids are another source of difficulty; and much caution is required for that reason, when we merely know that the uterus is enlarged; for it may contain something which, with or without a foetus, may prove to be a solid sanguineous mass, or the product of a false conception.

The term Mole is applied to a great variety of substances which are found in the uterus,—some say even of women who have never known man: nuns have had moles, and their chastity has not been suspected; or rather they have found advocates who maintain that such an occurrence may take place, and yet the woman

re never conceived. These are called *se moles*, and are said to consist chiefly sanguineous concretions. The menstrual blood probably is retained, distends the womb, the form of which it assumes, and is thus composed of successive layers: the colour and consistence of these masses vary much in different cases. But what are called *true moles* always contain the relics of a conception in some shape or other. It results from the death of the embryo, or the degeneration of the placenta, and of course its appearance will greatly depend on the period at which this death or degeneration takes place, and the length of time the organic remains lie deposited in the body of the organ: teeth and hair are frequently found in these morbid masses.

Moles are classified by authors as serous, aqueous, fleshy, hairy, stony, bony, &c. (the product of conception), and again sanguineous, windy, polypous, vesicular, &c. (not produced by sexual intercourse); but it may be sufficient for our purpose here to observe that they are often found of a very nondescript character. In a case related by Dr. Gooch, which strongly resembled pregnancy, but was attended with profuse discharges of water and blood, the patient died, and on dissection there was found in the cavity of the uterus which was about big enough to hold two foetuses) neither foetus nor hydatids (as some predicted), but a mass, about the size of a goose-egg, of stringy matter, like very soft placenta, and unattached to the inner surface of the uterus: this surface was hard and irregular, like a granulating sore; the walls were thickened, as in pregnancy, and of a dark red hue, and flaccid texture.

As to hydatids of the uterus, or those which resemble hydatids, as some prefer to consider them, they are a frequent cause of fallacy in obstetrical practice, and of course might happen to prove a serious source of mistake in medico-legal inspection. There is considerable contrariety of opinion as to the origin of these cysts—some holding them to be independent of sexual intercourse—others the reverse. The development of hydatid masses "in the uterus," says M. Desormeaux, "is most frequently, if not always, a consequence of conception;" and the generality of observers are agreed as to this fact, that they are owing to morbid alterations of the ovum and placenta. Velpeau even thinks that the hydatiform granulations which are commonly found on the external surface of the chorion, are the normal condition, or the natural state, of the part during the first two months after conception. It may be this as it may, the medical jurist should need be prepared for their occasional occurrence in the course of his practice.

This affection of the uterus is attend-

ed with remarkable enlargement of the abdomen; but it is also remarkable that the enlargement is generally disproportionate to the period of pregnancy, and that it becomes stationary after having advanced rapidly. A discharge of blood is also a common symptom of the gestation of hydatids; and it frequently gives alarm, from the apprehension of approaching abortion.

Polypus.—The only kind of polypus which can create difficulty is the interstitial—formed in the tissue of the uterus itself: the other kinds are in general easily recognized. But though we detect the presence of a polypus, we must not conclude hastily and at once that there is no foetus; for polypus may occur as a complication of pregnancy. The late Dr. Beatty, of Dublin, gives an account of a case in which a lady, a patient of his, who had a uterine polypus weighing nearly four pounds, miscarried; the foetus was one of about three months: the ovum was entire, the membranes not having been ruptured. The polypus itself was expelled in six days after, with pains resembling those of labour; the uterus was inverted by its descent, but on separation of the slight attachment between it and the tumor, it was easily restored to its place. Such cases, however, are considered to be very rare.

Extra-uterine pregnancy.—We sometimes meet with pregnancy of another sort, which, from some of its symptoms, might induce an inexperienced examiner to suppose that there was rather an ovarian tumor, or some other abdominal disease present, than actual pregnancy. The pregnancy may be extra-uterine. The ovum, from causes which are imperfectly understood, sometimes fails of being carried into the womb; it may not quit the ovary; it may stop on its way while yet in the fallopian tube; it may even reach the tissue of the uterus, and then become developed: nay, it may fall into the abdomen, it is said; and according to these several circumstances the pregnancy is termed ovarian, fallopian, interstitial, abdominal, &c.—mere special appellations, which are all included in the general name of extra-uterine. But wherever the ovum is deposited, a peculiar development takes place: a cyst is formed about it, which serves it for a uterus. And what is remarkable, and might, if not duly attended to, lead us into error, is, the peculiar development of the uterus itself: whether the ovum reach that organ or not, it enlarges and acquires at least two or three times its ordinary volume; and its inner surface is lined with a deciduous membrane. In a case observed by Chaussier, the neck of the uterus was sufficiently dilated to admit the introduction of the finger.

The results of extra-uterine pregnancy

are often very curious. They are frequently fatal, but have sometimes proved no impediment to the fecundity of the mother. I saw a case some time ago, in which a woman survived a fallopian pregnancy, and bore three children before the extra-uterine foetus was extracted. It was not till eight years after the conception that this event occurred: a spontaneous process of ulceration taking place near the umbilicus, the opening was enlarged, when the foetus was removed, and found to be in excellent preservation;—it measured 22 inches in length, and was well formed. The mother was still alive when I saw her, about a week after the operation; she was then a patient in a fever hospital, and not specially under treatment for the circumstances just mentioned.

Albert Meckel quotes a case which occurred in the year 1820, and has been recorded in some of the German journals. The wife of a rope maker remained pregnant for six years, during which time she gave birth to two living children. At length she was delivered *per naturales vias* of her weary burden, which proved to be a perfectly well-formed and mature foetus, dead of course, but the mother recovered. The pregnancy, in this instance, is supposed to have been of the interstitial kind.

The signs of extra-uterine pregnancy are generally too obscure and complicated to enable us readily to recognise it: in some cases it is not till after death, or at least till the period of natural labour has passed without delivery, that the fact is ascertained: previous to this we can at best only suspect the true state of things. Some particulars from a report on extra-uterine pregnancy, by Orfila, are deserving attention:—

“Upon reaching her chamber we found Madame N. in bed. She said she was six months gone with child, and told us that during that period the catamenia had been suppressed, and she had a constant feeling of weight and obstruction in the pelvis. We were further informed that the belly had increased in volume only on one side, and that its elevation had frequently occasioned the sharpest pains; that she had felt the infant move about the end of the fifth month, but since then had perceived no sort of movement. We proceeded to an examination, and recognised towards the right iliac fossa a tumor of a round moveable character, the corresponding region on the other side of the abdomen being much less swollen. The uterus was pushed to the left; it seemed to be about double the size of what it is in women who are not pregnant; the orifice of the uterus, elastic and elongated, was not closed; the hand was introduced into the womb, but no foetus was there. While moving the sides

of the vagina laterally and from below upwards, very unequivocal motions of *lottement* were distinguished. The *stethoscope* applied to various parts of the abdomen detected no contractions or pulsations. Furthermore, the patient suffered much from sharp pains in the whole of the lower part of the abdomen, and complained of excessive thirst. Her skin was hot, and she had much fever, sleeplessness, loss of appetite, and sometimes diarrhoea. We hence infer that Madame N. is pregnant, and that her pregnancy is extra-uterine.”

Post-mortem signs of pregnancy.—Where the female has died, and the question of pregnancy is raised, we have ample opportunity of deciding it on inspection of the internal parts. If we find the ovum with its normal appendages in the uterus, the case is clear; but even though the ovum be not detected, in consequence of the very early period of pregnancy—say in the first week or fortnight—we may still have evidence in the state of the womb, and particularly in the state of one or other of the ovaries. If there have been a recent conception, there must be a *corpus luteum* found: the presence of this body gives us the strongest possible assurance—indeed, I should say, the certainty of the fact. I have already noticed this very striking drawing from nature by Dr. Hope, and I beg once more to call your attention to it.

In the left ovary you see a regular *corpus luteum*, with the *cicatrix* belonging to it, marked by a bristle. There was a recent laceration of the hymen, gelatinous fluid was found in the cavity of the uterus and fallopian tubes, and such other changes were observed as, taken together, could not leave a doubt of the fact of recent conception. The characters of the *corpus luteum* ought to be well understood by the medical jurist, for mistakes have been made on the subject by many whose names have weight in the medical world. Such mistakes, however, are likely to be prevented in future by the complete account of *corpora lutea* given by Dr. Montgomery, in the masterly article already so frequently referred to. I must say, I never read a more convincing piece of medical criticism than that in which the Dublin professor exposes the misconceptions of several who treated on this point before him; and though he cannot be said to introduce any innovation in physiology by the views which he advocates—they being, in fact, those of Haller and Meckel—yet his details are so full and accurate, that he may be said to have made the subject entirely his own. On the present occasion I must be content with referring you to the article in question: in

FIG. 19.

In the next lecture I shall perhaps have to notice it more particularly.

Medico-legal Questions.

A variety of questions suggest themselves in relation to the pregnant state; but it will not be possible to notice more than a few. For instance: can we, as medical jurists, in any case pronounce a woman *not* pregnant?—Decidedly; when she labours under a physical disability, such as absence of a uterus and ovaries, and most probably when her age is such as to disqualify her. In the case of Johanna Southcote, who was sixty, some of her medical examiners were deceived by her fat and flatulence, but Johanna would never allow them to try test of the touch, “her burning spirit,” she said, “forbade her to submit to that.”

Again—can we determine, in the case of an abnormal pregnancy, whether a woman carries a mole? A set of symptoms are given by some authors, but, without entering into particulars, we may say that there is probably no difference between the retention of a mole and a dead foetus. We must take time, and abide the issue.

There are one or two other questions upon which the medical jurist ought to have clear and collected opinions. He may be asked, with reference to the moral character of a female who is pregnant, and who has no right to be so, whether, contrary to what she may assert, she must necessarily have been conscious of the act of coition? for women have again and again denied, in certain circumstances, that they have ever had to their knowledge carnal intercourse with a man. They were in some instances gone on even to the moment of delivery, apparently not knowing themselves pregnant, or insisting upon the impossibility that they should be so, and yet they had no connexion with any man. Pregnancy, of course, never happens without connexion (though it has been sometimes contended that it might) so that when the presence of that state is

established, the question is simply this—might a person have taken advantage of her, and got her with child without her knowing any thing about it? There are a number of cases on record, which would seem to determine the reply in the affirmative. Not to go back to the well known story of the girl who was laid out for dead, and who was impregnated in this condition by an ecclesiastic, who watched by her bier, in a compendium of midwifery not long since published* there is the following case—“A maid at an inn, who was always thought to be virtuous, and bore a good character, began to enlarge in a way which excited suspicions of pregnancy. She solemnly declared that she never had connexion with any man. At length she was delivered, and was afterwards brought before a magistrate to swear to the father; but she repeated her former declaration. Not long afterwards a postboy related the following circumstances: that one night he came late to this inn, put his horses into the stable, and went into the house; he found all gone to bed except this girl, who was lying asleep on the hearth-rug, and without waking her he contrived to gratify his desires. This shews,” adds the author, “that impregnation may take place without the knowledge of the female.” A case, the complete counterpart of this, is given by Dr. Montgomery, in his essay on the Signs of Pregnancy.

Capuron says “It is a fact, which experience has more than once confirmed, that a woman may become pregnant while in a state of hysteria—under the influence of narcotics—during asphyxia, drunkenness, or deep sleep; and consequently without being conscious of it, or sharing the enjoyment of the man who dishonours her,” and, in proof, he mentions having attended a young woman who was got with child while totally un-

* Compendium of Gooch's Lectures on Midwifery, p. 81.

conscious, being buried in a deep sleep, produced by punch given her by her paramour. Such cases as these ought to render us careful in pronouncing a severe opinion, when we are consulted in charges of concealment of the birth; for if a woman may become pregnant without knowing it, there is some chance, if she be not very quick-witted or have experience, that she shall go on to the time of her delivery unconsciously, and without having made any preparation for that event, whereby the life of the infant is compromised.

Women have often been really ignorant of their condition, though they have confessedly incurred the risk. There is a well-authenticated story of a simple-minded girl, who yielded to her lover in a bath, because he told her that no consequence would ensue from a connexion under such circumstances: she believed him, and could not be persuaded that his word was untrue till the moment of her delivery. Klein also, as quoted in Henke's *Abhandlungen*, gives two cases which came under his cognizance; one, that of a married woman, who, even in the pains of labour, believed herself ailing otherwise than with pregnancy; and the other that of a young girl, who was confident, even in the ninth month, that she was not pregnant, because she had had only one connexion; and her seducer told her that in such a case there could not possibly be any consequences. Thus there may evidently be three states to account for the ignorance of the female:

1. Some disease resembling pregnancy;
2. Menstruation (as it sometimes does) occurring after a fruitful intercourse; and
3. An erroneous impression deeply rooted.

The practitioner had need to be carefully on his guard when he has to deal with women who make these assertions; for while he bears in mind the possibility of the truth of what they say, he must also recollect the obstinacy with which they often maintain that they are not pregnant, when they know they are, and yet dare scarcely confess it to themselves. "It appears difficult to explain," says Dr. Gooch, "the obstinacy of assurances which those who make them know to be false, but I suspect they deny to the last that they *can* be pregnant, because they hope to the last that they *are not* so. Another circumstance likely to bias the medical man, is the respectability of the patient; but this, too, must be disregarded. Single women sometimes become pregnant in all ranks of life, not only among the low but among the high, and not only among these, but in the middle ranks; and the practitioner, in his intercourse with the world, will often be placed in puzzling situations, and have to listen to very curious disclosures."

I may here mention, that the Prussian law refuses to believe that a woman can arrive at an advanced stage of pregnancy without knowing it: "after the 30th week," it expressly states, "no plea of ignorance can be admitted."

Another medico-legal question connected with pregnancy is, whether a woman in the pregnant state is always to be accounted a responsible agent—whether, in fact, those longings, and peculiar states of mind which we know to be common in pregnancy, should form any excuse for a female who would be otherwise criminally judged? Medical men have sometimes been consulted on this head, and the inquiry has generally been limited to this—whether a pregnant woman may so be got the better of by her imagination, and may have her will so depraved, as to be impelled to commit certain crimes—more especially theft? I believe the truth to be, that such an admission is in many cases unavoidable; but it would be a dangerous precedent to admit it generally: social order might suffer severely from such an indulgence: a woman with a propensity to thieving in all states of her system would have a dangerous latitude allowed her, if she were protected by her pregnancy. If, however, the disturbance of the mind be extraordinary, the medical jurist who is consulted will not have much reason to hesitate in excusing the woman: but if otherwise, it will be his duty to refer the magistrate to some other quarter for the elucidation of the question—for it does not properly belong to medicine. The legal functionaries will in general be the best judges how to act, by comparing the character of the accused in her ordinary unimpregnated state with her conduct while pregnant: by considering her circumstances, whether she is in no want—or whether she is distressed: considerations such as these will throw more light on the question, than any medical evidence to prove that the woman is of an irritable temperament, or of a melancholy or hypochondriacal state of mind.

LECTURES ON

MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,
BY JON. PEREIRA, Esq., F.L.S.

LECTURE LIV.

Strychnia.

History.—On the 11th December, 1818, Pelletier and Caventou announced to the

stitute the discovery of a new alkali, to which they proposed to term *vauqueline*, because the celequelin was the first to signalise the existence of an organic alkali. Massieu proposed to denominate it *tetanine*, from its effects, as this term would be in harmony with morphine and strychnine. The term *strychnia*, however, is considered most appropriate, and, as has been usually adopted.

History.—Hitherto it has been found in five species of the genus *Strychnia*, *S. nux vomica*, *S. Ignatia*, *S. Tienté*, and *S. Guianensis*. Probably, it is contained in *S. Guianensis*, which is the American poison *Uraria* (formerly associated with another species), and is always combined with it.

Preparation.—There are several methods by which *strychnia* may be procured; one of the following:—Boil *nux vomica* in water, evaporate the strained liquor to the consistence of syrup, and precipitate by slacked lime. The precipitate is to be collected on a filter, washed first with water, and then with weak spirit, and afterwards pulverised. It is then digested in spirit, and the alcoholic solution is separated: the residuum is *impure strychnia*. To purify this add dilute sulphuric acid, boil with animal charcoal, and precipitate by ammonia: the product is *precipitated strychnia*. To separate the *strychnia* from the *brucia* which this usually contains, it is dissolved in weak spirit, which dissolves the *brucia* and leaves the *strychnia*. The two alkalies are then converted into nitrates; and the *strychnia* may be separated from the *brucia* by this operation.

Process.—By boiling *nux vomica* in water, we obtain a solution of the alkalies (or gasurates) of *strychnia* and *brucia* along with gum and some coloring matter. The lime which is added to precipitate the strychnic (or gasuric) acid, separates the *strychnia* and *brucia*. The residue, with water and weak spirit, is washed, and the impurities (the gum and coloring matter) is removed. By digestion in spirit we obtain a solution of *brucia*, and coloring matter, and substitute the impure *strychnia*. The addition of sulphuric acid two solutions of the alkalies are formed; and by the addition of charcoal the coloring matter is removed. By the addition of ammonia, the *brucia* and *strychnia* are precipitated. The *strychnia* is soluble in weak spirit, is separated from the *brucia*.

Preparation given in the new London Pharmacopoeia is the following:—Boil for

an hour two pounds of bruised *nux vomica* with a gallon of rectified spirit, in a retort with which a receiver is connected. Pour off the liquid, and boil the residuum with another gallon of spirit and the recently distilled spirit. Having poured off this liquor, treat the residuum a third time in the same manner. Express the *nux vomica*, and distil the spirit from the strained and mixed liquors, and evaporate the residuum to the consistence of an extract, which is to be dissolved in cold water and filtered. Evaporate by a gentle heat to the consistence of syrup, and to the liquor, while warm, add gradually a sufficient quantity of magnesia to saturate it, shaking them together. Set aside for two days, then pour off the supernatant liquor. Express what remains wrapped in linen; boil it in spirit, strain, and distil the spirit. Add a very little dilute sulphuric acid mixed with water, and macerate with a gentle heat. Set aside for twenty-four hours, that crystals may form. Express and dissolve these. Lastly, add ammonia to these, dissolved in water, shaking now and then, that the *strychnia* may be precipitated. Lastly, dissolve this in boiling spirit, and set aside, that pure crystals may be formed.

Theory.—The theory of the pharmacopoeial process is readily comprehended. The watery solution of the alcoholic extract contains the strychnates of *strychnia* and *brucia*: the magnesia decomposes these, abstracts the strychnic acid, and precipitates the *strychnia* and *brucia*. The sulphuric acid which is added converts them into sulphates, which are decomposed by the ammonia, *strychnia* being precipitated along with some *brucia*.

Properties.—Pure *strychnia* is a white, odourless, intensely bitter, crystalline substance, the form of the crystal being the octahedron, or four-sided prism. When rapidly crystallized, it assumes a granular form. It is fusible, but not volatile; decomposing at a lower temperature than most vegetable bodies. Though so intensely bitter, it is almost insoluble in water, one part of *strychnia* requiring 6667 parts of water, at 50°, to dissolve it; that is, one grain needs nearly fourteen ounces of water to hold it in solution. It requires 2500 parts of boiling water to dissolve it. It acts on vegetable colours as an alkali, saturates acids forming salts, and separates most of the metallic oxides (the alkaline substances excepted) from their combinations with acids. In some cases part only of the metallic oxide is precipitated, a triple salt being formed. This is the case with the sulphate of copper: *strychnia* boiled with this salt throws down part of

the oxide of copper, while a green solution of sulphate of copper and strychnia remains.

Composition.—This base is anhydrous. According to Liebig it consists of—

30 atoms carbon, 30×6 ..	180
16 atoms hydrogen	16
1 atom nitrogen	14
3 atoms oxygen, 3×8	24
<hr/>	
1 atom strychnia	234

Characteristic tests.—Pure gallic acid does not precipitate it. Tannic acid, or infusion of galls, precipitates the tannate of strychnia. The strychnia of the shops is coloured red by nitric acid, though pure strychnia is not. The substances present in ordinary strychnia, which thus become coloured by nitric acid, are brucia and a yellow incrustable matter, which is with difficulty separated. This red colour is destroyed by the addition of some deoxidizing agents, as sulphurous acid, and sulphuretted hydrogen. Hence the phenomena of coloration appear to depend on oxidizement. This colour produced by nitric acid passes successively from red to yellow. By a prolonged action of the nitric acid, oxalic acid is formed. When the solution has become yellow by nitric acid, deoxidizing agents no longer decolorize it. If potash be added to a very concentrated solution of a strychnia salt, which has been reddened by nitric acid, an orange precipitate is formed. An excess of water redissolves this precipitate. The salts of iron are not coloured by the addition of strychnia. Another character of strychnia is its action on the salts of copper before mentioned.

Salts of Strychnia.—When pure, they are for the most part crystalline, white, and very bitter. They possess the following chemical characters:—

1. They are precipitated by the alkalies and their carbonates.
2. As usually met with in the shops, they are reddened by nitric acid.
3. They are precipitated by tannic, but not by gallic acid.
4. They are unchanged by the action of the persalts of iron.

1. *Sulphates:* (a.) *Neutral.*—Exists in the form of small cubes, soluble in ten parts of water at 59° Fahr., and of course in a less quantity at a higher temperature. When heated, it fuses and loses three per cent. of its weight, probably water of crystallization: but Liebig detected no water in sulphate dried at 212° ; so that if it had contained water, this temperature must have expelled it. It consists of

1 atom strychnia	234
1 atom sulphuric acid	40

274

(b.) *Bisulphate.*—It has an acid and bitter taste, and crystallizes in slender needles.

2. *Nitrates:* (a.) *Neutral.*—It crystallizes in pearly needles, grouped in stars. It is much more soluble in hot than cold water; is slightly soluble in alcohol, but does not dissolve in æther. When heated to a little above 212° , it decomposes and becomes yellow, swells up, detonates slightly (but without the disengagement of light), and leaves a carbonaceous mass behind. If the strychnia contain brucia, the nitrate has a reddish tint.

(b.) *Binitrate.*—Crystallizes in very fine needles. When heated, decomposes, becomes red, and detonates with the disengagement of light.

3. *Hydrochlorate or Muriate.*—This salt crystallizes in four-sided needles, which lose their transparency in the air. It is much more soluble in water than the sulphate. When heated, it is decomposed with the evolution of hydrochloric acid.

Physiological effects.—The effects of strychnia are of the same kind as those of nux vomica, but more violent in degree. As ordinarily met with in the shops, it may be regarded as about six times as active as the alcoholic extract of nux vomica. The following are a few examples of its poisonous operation:—

(a.) *On animals.*—Dr. Christison says, "I have killed a dog in two minutes with a sixth part of a grain, injected, in the form of alcoholic solution, into the chest; I have seen a wild boar killed in the same manner with a third of a grain, in ten minutes." Pelletier says, "half a grain blown into the mouth of a dog produced death in five minutes." Half a grain applied to a wound in the back of a dog caused death in three minutes and a half. In all these and other instances death was preceded and accompanied by tetanus. The salts of strychnia act in a similar manner.

(b.) *On man.*—Some individuals are more susceptible of the action of strychnia than others. Andral has seen a single pill, containing one-twelfth of a grain, cause slight trismus, and the commencement of tetanic stiffness of the muscles; while in other cases, the dose may be gradually increased beyond a grain with comparative little effect. The largest dose I have given is a grain and a half, and this was repeated several times before the usual symptoms indicative of the affection of the system came on.

Uses.—The uses of strychnia are precisely those of nux vomica already mentioned.

Mode of exhibition.—Strychnia is usually given in doses of one sixth of a grain, gradually increased until its effects on the muscular system are observed. It is commonly made into pills, by means of conserve of roses; or it may be dissolved in alcohol, or in acetic acid. The salts of strychnia, as the sulphate, nitrate, or hydrochlorate, may be given in doses of one-twelfth of a grain. In amaurosis strychnia is employed after the endermic method, as already noticed.

Antidotes, and mode of detection in the contents of the stomach.—These are the same as for nux vomica, before mentioned.

Brucia.

History.—This alkali was discovered in 1819, by Pelletier and Caventou, in the bark called *false angustura*, which was at one time supposed to be the product of the *Brucia antidysenterica*. As, however, this is now known not to be the origin of the bark, the term brucia is of course objectionable, and some have proposed to term it *pseudo-angustine*.

Native state.—It exists not only in this *false angustura* bark, but also in nux vomica and St. Ignatius's bean; in the two latter cases it is associated with strychnia, and is in combination with igasuric or strychnic acid, but in the *false angustura* bark it is combined with gallic acid.

Preparation.—It is prepared by the same process as already described for making strychnia.

Purification.—To purify this alkali, convert it into an oxalate, which is insoluble, or nearly so, in alcohol. Wash with cold alcohol, to remove the colouring matter. Afterwards, decompose the oxalate by magnesia, and separate the brucia by boiling alcohol.

Properties.—Brucia in the anhydrous form, as obtained by fusing it, has a waxy appearance; but when combined with water, it is capable of crystallizing, the form of the crystals being oblique four-sided prisms; or sometimes the crystals have a pearly laminated appearance, something like boracic acid. Its taste is very bitter, though less so than strychnia. When the crystallized brucia is heated, it gives out 17 per cent of water, and fuses.

Solubility.—It is soluble in 850 parts of cold, or 500 parts of boiling water; but the presence of colouring matter, of which it is difficult to deprive it, promotes its solubility. It is very soluble in alcohol, but is insoluble in æther and the fixed oils, and is very slightly soluble only in the volatile oils.

Composition.—According to Liebig it consists of

32 atoms carbon	192
18 atoms hydrogen	18
1 atom nitrogen	14
6 atoms oxygen	48
<hr/>	
1 atom anhydrous brucia	272
6 atoms water	54
<hr/>	
1 atom crystallized or anhydrous brucia	326

Characteristics.—Nitric acid assumes a fine red colour when added to brucia: de-oxidizing agents, as sulphuretted hydrogen and sulphurous acid, decolourize this solution. Iodic and chloric acids produce the same phenomena as nitric acid.

Salts of brucia.—These are readily formed by saturating dilute acids with brucia. They possess the following properties:—for the most part they are soluble and crystallizable, and have a bitter taste. They are decomposed by potash, soda, ammonia, the alkaline earths, morphia, and strychnia, which precipitate the brucia. They are precipitated by tannic acid. Nitric acid colours them as it does free brucia.

Physiological effects.—The effects of brucia on man and animals appear to be precisely similar to those of strychnia, though larger doses are required to produce them.

Uses.—The uses of brucia are those of strychnia and nux vomica before related.

Mode of administration.—The dose of brucia is from half a grain gradually increased to about five grains. It may be given in the same way as strychnia.

Antidote.—Poisoning by brucia is to be treated like that for nux vomica.

Strychnos Ignatia.

St. Ignatius's bean, says Alston, came into the Dutch shops about the latter end of the 17th century. But there is some reason to suspect they were known long before this, and are probably the substances which in the Latin translation of Serapion was denominated *nuces vomice*. Dale gives, as one of their synonymes, "Igasur, seu Nux vomica legitima Serapionis." They are obtained from the *Strychnos Ignatia* (called by some *Ignatia amara*), a tree indigenous to the Philippine Islands, whose fruit is smooth and pyriform, and contains about twenty seeds. These seeds, the St. Ignatius's beans of the shops, are about the size of olives, rounded and convex on one side, and somewhat angular on the other. Externally they are brownish, with a bluish grey tint. Within the envelopes of the seed is a very hard horny or cartilaginous albumen, in whose cavity

is contained the embryo. These seeds have been analysed by MM. Pelletier and Caventou, who found their constituents to be the same as those of *nux vomica*, though in somewhat different proportions. Their effects, therefore, are similar.

False Angustura Bark — Bark of Strychnos — (?)

History.—In 1804, Dr. Rambach a physician at Hamburgh, observed that some specimens of angustura bark, said to be from the East Indies, acted as a powerful poison; and as repeated cases of poisoning occurred with the same substance, an order was issued forbidding the use of angustura bark. On the 15th October, 1815, the Commission of Health of the grand duchy of Baden ordered all the angustura bark in the possession of the apothecaries to be seized and placed under a seal; the physicians at the same time receiving an intimation that they were not, in future, to prescribe this bark. Similar ordinances were issued in Austria, Bavaria, and Wirtemberg.

The origin of the bark is said, by Batka, to be as follows: a quantity of it was imported from the East into England, and not being saleable was sent to Holland; and as no better means of getting rid of it offered, it was mixed with, and sold as, genuine angustura or cusparia bark.

Botanical history.—Great obscurity has long existed as to the tree which yields it. At first it was attributed to the *Brucea ferruginea*, or *antidysenterica*, a native of Abyssinia, belonging to the family Xanthoxylaceæ; but in 1831 Geiger had occasion to examine the bark of the *B. ferruginea*, and found that it had no resemblance to false angustura. Now the composition and effects of this bark render it in the highest degree probable that it is the product of some tree of the family Strychnaceæ, most probably of the genus *Strychnos*; Batka says of the *S. nux vomica*, or some neighbouring species. I have carefully examined the specimens of this genus in the herbarium of the Linnæan Society, and found on one of the native specimens of the *nux vomica* plant, in Dr. Wallich's collection, a slight fungous-kind of excrescence, somewhat analogous to that found on the false angustura bark.

Description of the bark.—It occurs in quills or flat pieces (*angustura falsa convoluta seu plana*), or in pieces arched backwards, having the twisted appearance of dried horn. It is more compact and heavy than real angustura bark. The epidermis varies: sometimes it consists of a dark fungoid or spongy rust-coloured layer (hence the term *angustura ferruginea*), which

is only the altered epidermis; at other times it is not thick, not fungous, but covered with numerous whitish prominences, formerly supposed to be some species of lichen, but now known to be only an epidermoid alteration, the more advanced stage of which constitutes the rust-coloured layer already mentioned. The powder is intensely bitter, and of a yellowish white colour.

Composition.—The following are the constituents of this bark, according to the analysis of MM. Pelletier and Caventou:—

1. Gallate of brucia.
2. Fatty matter (not deleterious).
3. Gum (a large quantity).
4. A yellow colouring matter (*Strychnochromin*) soluble in water and alcohol.
5. Sugar (traces).
6. Lignin.

Chemical tests.—By reference to the constituents of this bark, the action of the tests for it may be readily understood. An infusion of this bark reddens litmus, in consequence of the excess of acid present. Strong nitric acid added to this solution produces a red colour; and by dropping the acid on the inner surface of the bark, a blood-red spot is produced: in both these cases the effect arises from the action of the acid on the brucia. If nitric acid be applied to the external surface of the bark, it produces a deep green colour, in consequence of the action of the acid on the yellow colouring matter. Infusion of galls added to the infusion of this bark occasions a white precipitate of the tannate of brucia. Sulphate of iron colours the infusion green, from its action on the yellow colouring matter.

Physiological effects.—(a) *On Animals.*—The experiments of Pfaff, the Vienna Faculty, Emmert, Meyer, Orfila, Magendie, and Jäger, have shown that it is a powerful poison to dogs, rabbits, wolves, and other animals. Thus eight, twelve, or eighteen grains of it kill dogs, the symptoms being precisely the same as those of *nux vomica* already detailed. (b) *On Man* it also acts as a powerful poison. Emmert mentions that a boy who had taken by mistake the decoction of this bark died therefrom. His intellectual powers were unaffected; he entreated his physician not to touch him, as violent convulsions were immediately brought on; he was powerfully sweated, but did not vomit. Professor Marc was nearly poisoned by swallowing through mistake three quarters of a liqueur glassful of a strong vinous infusion.

Uses.—It is sometimes employed for the

action of brucia, in consequence of alkali existing in this bark unmixed with strychnia.

Indica.—The treatment of cases of poisoning will be precisely the same as for strychnia.

Upas or Java Poison.

The poison tree of Java has been rendered notorious principally in consequence of gross fabrications and misstatements made concerning it about the year 1785 by a person of the name of Foersch, who had been a surgeon in the service of the Dutch East India Company. Malabar, says this author, when they receive sentence of death, are offered the chance of life, if they choose to collect this poison, and although every precaution is taken to prevent its action on the system, seven hundred persons who went to

collect it, only two returned alive; and from their reports, no living being (vegetable or animal) is to be seen for a wide tract of country around it. Foersch says he himself found this to be the case for eighteen miles in every direction from the tree!!! Darwin, believing this report, has made it the subject of his muse in the third canto of his "*Lovers of the Plants*."

1. *Upas Antiar*.—The account given by Foersch has long been known to be a gross falsehood and imposition, principally by the researches of Dr. Horsfield and M. Leschinault. From their accounts, it appears that the true poison tree of Java (the *Arbor toxicaria* of Rumphius), is called *Antibar* or *Antiar* (*Antiarum toxicaria* of botanists), and belongs to the family Urticaceæ. It is one of the largest forest trees of Java, being from 60 to 100 feet high. Here is a drawing of it, taken from a recent publication of a German botanist.

FIG. 146.—*Arbor toxicaria*. *Ipo.* Rumph. *Antiarum toxicaria*. Leschinault.

will observe he has strikingly represented the non poisonous qualities of its leaves, by his picture of the richness of the surrounding vegetation, by the

parasitic plants, and birds depicted on the tree, as well as by the natives in its immediate neighbourhood.

Preparation.—The juice contained in the

bark of this tree is viscid, milky, and bitter. It is extracted by incision, and when boiled to the consistence of an extract with the juice of arum, galanga, onions, garlic, pepper, and capsicum, forms the *Opas* or *Upas* poison, and which is employed for the purpose of poisoning arrows.

Composition. — Pelletier and Caventou analysed this poison, and found it composed of—

1. A peculiar elastic resin.
2. Slightly soluble gummy matter, analogous to bassorine.
3. A bitter matter, soluble in alcohol and water, and composed of three substances:
 - (a). A colouring matter, absorbable by charcoal.
 - (b). An undetermined acid.
 - (c). A substance precipitable by the tincture of galls, and which is the active principle of the poison. As it is probably alkaline, it has been termed *Antiarine*.

Effects. — The symptoms which result from its action on the system indicate a double influence exercised on the nervous system and stomach. According to Andral, its action is not absolutely identical with the *Upas Tienté*, to be mentioned presently: the first produces clonic convulsions, or convulsions with alternations of relaxation; the second causes tonic convulsions, or tetanus properly so called. Moreover, the *Upas antiar*, after becoming absorbed, irritates the stomach. According to Sir B. Brodie, death results from the heart being rendered insensible to the stimulus of the blood.

2. *Upas Tienté.* — But besides the *Upas antiar* just described, there is another poison yet more violent, produced in Java from a large winding shrub called the *Tienté* or *Tshittik* (the *Strychnos Tienté* of botanists), belonging to the family Apocynaceæ. Its roots extend themselves horizontally sometimes to a considerable length; and its stem occasionally ascends to the top of the largest forest trees.

Preparation. — To obtain the poison, the bark of the tree is boiled in water, and the decoction filtered and evaporated to the consistence of an extract: onions, garlic, pepper, galanga, ginger, and capsicums, being added to render the supposed charm good.

Composition. — This poison also has been analysed by MM. Pelletier and Caventou. It contains—

1. Strychnia, combined with an acid (igasuric?)
2. Reddish brown colouring matter (*strychno-chromine*), which becomes green when mixed with nitric acid.

3. Yellow soluble colouring matter, which is coloured red by nitric acid.

These celebrated chemists detected *brucia* in this poison.

Effects. — The active principle of this poison being strychnia, its effects are precisely similar to those produced by *nuxvomica* and *strychnia*. Thus, when applied to wounds, injected into the serous sacs or blood-vessels, or applied to the mucous membrane, it produces tetanus, asphyxia, and death. Forty drops of *upas* dissolved in water, and injected into the pleura of an old bay horse, gave rise almost immediately to tetanus and asphyxia, and the animal died after the second attack.

Lignum Colubrinum, or Snake-Wood. (*Strychnos Colubrina.*)

In countries infested with poisonous serpents, the natives have usually some substance which is fancied to possess the power of preserving them from the bites of these poisonous animals; and thus we have various articles, seeds, roots, and woods, which have the word *snake* prefixed to them.

In Asia there has long been known a wood which has been supposed to possess the above-mentioned property, and it has, therefore, been denominated *snake wood*, or *lignum colubrinum*. The specimens, however, met with in commerce, show that there are various substances to which this term is applied, some being the wood of the root, others the wood of the stem.

This wood is probably the produce of *Strychnos Colubrina*, though occasionally it is procured from other species of *Strychnos*—especially *S. Nuxvomica*.

According to the analysis of Pelletier and Caventou, this wood has the same constituents as the bean of *St. Ignatia*, though in different proportions. Thus it contains more fatty and colouring matters, much less strychnia, and, in the place of bassorine and starch, a larger quantity of woody fibre.

Its action, therefore, is precisely similar to the before-mentioned poisons.

Tanghin Poison.

From the kernel of the *Tanghinia veneniflua* or *Cerbera Tanghin*, a plant belonging to the family Apocynaceæ, is obtained the celebrated *Tanghin* poison. A single seed (which is not larger than an almond) is said to be sufficient to destroy twenty persons!! It is (or was) used in Madagascar to determine the guilt of suspected persons. Those who are able to withstand the ordeal (that is, those unaffected by the poison) are considered innocent, and vice versa.

CEREBRAL AFFECTIONS FROM DEFICIENCY OF CRANIUM.

Editor of the Medical Gazette.

R,

Medical and Physical Journal,
 ed in London, for October, 1821,
 has been written by Sir Gilbert
 on the efficacy of mechanical
 ssion in certain cases of hydroce-

He says, "In reflecting on the
 stances which characterize the
 and description of hydrocephalus
 me of the chief of which are—
 is very seldom met with but in
 rly life, and most commonly in in-
 before the bregma is closed; that
 s in most cases a preternatural
 the head; and that it is usually
 d with a rachitic state of the
 and a general scrofulous flacci-
 the soft parts, and runs in parti-
 amilies—it occurred to me that
 tension of the head and bregma
 g to a want of firmness and due
 ice in the bony compages of the
 which consequently yields to that
 f pressure with which the brain,
 growth, acts on its parietes. In
 ng further on the subject, it ap-
 to me conformable to some of the
 pproved principles of physiology,
 s there is a certain degree of ten-
 d pressure necessary to the sound
 on and action of parts, the with-
 g of this, by inviting afflux and
 tion, produces serous effusion;
 the like reason there may be a
 icy of that interstitial absorption
 which the healthy state of this and
 er parts of the living frame de-
 ' Sir G. Blane relates one well-
 l case, shewing its advantages.
 ly the following surgical case, in
 a large portion of the bony scalp
 ficient, may tend to support the
 doctrine, as I could assign no
 ause of death but the want of the
 upport to the encephalon.

ge Patterson, aged five years and
 onths, received a fracture of the
 und posterior part of the left side
 os frontis, and anterior edge of
 rietales adjoining, which exfo-
 leaving an aperture in the bony

structure three inches by two inches in
 size. The wound healed; he remained
 well till the age of thirteen, after which
 he became subject to epileptic fits,
 which returned at times, increasing in
 severity till the age of sixteen, when
 they would put on every symptom of
 compression of the brain, till at last he
 would lie in a state of complete insen-
 sibility, with stertorous breathing, for
 seventy hours at a time. Treatment
 consisting of general and local bleed-
 ing, mercurials, arsenic, antispasmodics,
 quinine, counter-irritation through the
 skin and stomach, by means of ant. tart.,
 all proved unavailing, till death termi-
 nated his sufferings Oct. 17, 1831, at
 the age of seventeen years.

Autopsy, ten hours after death.—On
 viewing the body, the only external de-
 fect was in the integuments of the back
 part of the scalp and ears, which were
 of a livid colour. On dissecting the in-
 teguments off the head there was extra-
 vasation of blood, with the appearance
 of contusion on the back part of the
 skull, opposite the ridge of the occipital
 bone. On removing the calvarium the
 dura mater adhered closely throughout,
 but was perfectly healthy; it was want-
 ing over the original wound, the cover-
 ings of which were as follows—integu-
 ment, tunica arachnoides, and pia mater.
 The sinuses were gorged with venous
 blood, also the veins leading to them
 presenting an unusual size. The tunica
 arachnoides healthy; the convolutions
 of the hemispheres of the brain were
 flattened; in the ventricles was found
 a small quantity of a sero-sanguineous
 fluid; the cortical and medullary sub-
 stances of the cerebrum and cerebellum
 firm, without any infiltration. The tho-
 racic and abdominal viscera presented
 every appearance of health. The mind,
 or intellectual constitution, was rather
 of a superior order than otherwise; me-
 mory strong. He was amiable in his
 disposition; fond of horse exercise and
 shooting; very lively between the pa-
 roxysms, which interval sometimes last-
 ed three months.

It might be asked, why was he not
 subject to epilepsy between the time of
 the accident and the commencement of
 them, at thirteen years of age? On in-
 quiry I learned, from the time the
 wound healed over till he was thirteen,
 he wore a metallic plate, secured on

with a tight bandage, thereby making artificial pressure.

Should you consider the above worthy of insertion in the *MEDICAL GAZETTE*, I shall feel obliged by your giving it publicity; and remain, sir,

Yours most respectfully,
JOHN GRANTHAM.

Crayford, Kent,
Dec. 21, 1836.

HOMŒOPATHIC DOSES.

DO THE HOMŒOPATHS COMPREHEND THEM?

To the Editor of the Medical Gazette.

SIR,

THE annexed extracts from a letter received from a clerical friend, to whom I had lent Hahnemann's and Quin's books on Homœopathy, amused, and at first certainly somewhat startled me, until I had gone through one or two of the calculations and verified their accuracy.

I have never before seen the extreme absurdity of homœopathic doses so clearly demonstrated; and could you find room for their insertion in your valued periodical, you will oblige, sir,

Your obedient servant,
THOS. H. SMITH.

St. Mary Cray, Kent,
Dec. 22, 1836.

"Many thanks for the books on Homœopathy. I have read them attentively: the result has amused me, as it may amuse you also. The point to which I will first allude is the excessively minute quantities in which the homœopathists profess to administer their medicines. A physician of our acquaintance, as he was laughing at these small doses a few days ago, observed that it was like throwing a grain of an active medicine into the Thames. He meant to exaggerate, but he in fact, as I shall presently shew, *enormously underrated the degree of attenuation*. Two decillionth parts of a grain is a favourite homœopathic dose. Now trillions and decillions are very pretty words, to which, however, we can affix no definite or even approximate idea; we are not aware how the powers of numbers mount up, unless we have oc-

casional to apply our minds to a close and accurate investigation of them. When we talk of a decillion, we know we are naming a number which consists of an unit with sixty cyphers in its train; but if we would form any sort of notion of its magnitude, we can only reach it by taking some enormous intermediate integer.

The diameter of the earth is about 8000 miles; the solid contents of spheres vary as the cube of their respective diameters. The population of the world has been calculated at about eight hundred millions; and a homœopathic dose of opium amounts to two decillionth parts of a grain. Upon these data we proceed. From one grain of opium abrade an atomic particle which shall bear the same proportion to the whole grain, that a spherule one-thousandth part of an inch in diameter bears to the globe upon which we stand: divide this particle into homœopathic doses, and cause each individual on the face of the earth to swallow a dose every second, it will require twenty millions of years to take the particle described.

It will, I apprehend, be of little moment whether you administer opium in these ideal quantities, or distilled water, or—moonshine. If the Lord Mayor's orders respecting the provisions spoiled at the fire in Tooley-street were really carried into effect, there can be no porter brewer using Thames water who has not administered to every half-pint customer very alarming doses, homœopathically speaking, of the *arsenate of ham*. This should certainly be looked to.

But to our illustration above—Opium: it may be objected that it is really a powerful medicine: let us glance at some drug of milder properties. Capsicum I use to my boiled beef in formidable allopathic doses; let us see how Hahnemann administers it. This he attenuates to the ninth degree; that is, he would give a globule of sugar or spirit, which are his only vehicles, containing one-trillionth part of capsicum; *that is, one part of capsicum to one-trillion of the same parts of sugar*. Now suppose we wished to attenuate one grain of capsicum in this proportion, we should, of course, require one trillion grains of sugar. Will you tell me off-hand in what space, within a ship-

ou might stow away a trillion of sugar? A West India-tous is a very large West indeed; if we freight ten ships, and let them each thousand voyages, there remain above half a million loads at Jamaica, out of grains. The calculation is gh, and my accuracy, there-ly tested.

ed to fancy an illustration rainids. The area of the id is 480,250 square feet, ght 499 feet, call it 500; its solid contents are

10 or 80,041,666 cubic feet.

at this moment the specific gar, but that of pure spirit her vehicle) I have. The cubic foot of spirit is 800 ltiply this by 437½, you get ums in the cubic foot; di-llion by this number, and, that you have above two billions of cubic feet in a minutes; extract the cube it is 13,750 in feet, which ngth of each side of a cubi-ich will hold a trillion of ure spirit,—that must be niles and a half long, two half wide, and two miles igh; or, comparing it with ls, it would require above housand six hundred pyra-ain spirit enough to dilute f capsicum. You will thus friend would certainly poi-imes with his drop of lau-

comparing it with the views of others, and to present it in the form of an essay.

I am in possession of at least one hundred notices of its internal use, during the last twelve months, at the dispensary. Although one-half of these has been dismissed without comment, there is not one but has either confirmed my general knowledge of this substance, or caused it to be directed into new channels of research.

The diseases in which I have seen its efficacy proved are principally those of tegumentary membranes, whether affected in their functions or organization; and of the fibrous tissues; and its virtues depend on a tonic and stimulant power.

As a remedy acts through fixed laws, and is unable to adapt itself to the circumstances of its administration, it is the latter which we are constantly considering after our ideas of the former are made perfect; and through these that we are to extend our knowledge. A stimulant, for example, increases action; but it is whatever kind of action may exist at the time of its application, whether an inflammatory, irritable, or merely debilitated action; therefore our first object is to ascertain which of these states is present, and to convert one into another, according to the end we would accomplish, and the peculiar state of system on which we are desirous to practice.

In many disorders in which final advantage may be anticipated from the hydriodate of potass, there are states of the system which forbid its use. It cannot be given in the acute stages of rheumatism, because of the febrile symptoms; but directed with skill to certain varieties of the chronic, it is a specific. This distinction arises also in acute and chronic diseases of the skin; and in disorders where there may be no excitement of the system, although there exist local irritation of the stomach or intestinal canal, this abnormal state will suffer aggravation instead of tone being directed to the system, or relief to the disease.

The hydriodate of potass, when internally exhibited, may perform the office of a tonic, the circumstances attendant on its exhibition being adapted to this kind of action. If, for instance, the mucous tissues be in a debilitated state

ON THE VIRTUES

DATE OF POTASS,

EDIAL AGENT IN DISEASE.

T. C. HAKE, M.D.

to the Brighton Dispensary.

ected the hydriodate of po-
nal administration in many
ive been induced to embody
ce of its properties, without

it will elevate them to their natural tone, and will afterwards, if pursued, assert its influence as a stimulant over distant organs, or the one to which its action may have been directed by superior art.

If the tegumentary membrane of the stomach suffer irritation through inevitable sympathy with disease, so as to be irreducible beyond a limited extent so long as the cause exists, it should be antagonized by counter-irritants, such as henbane, hemlock, lettuce, and the like, according to their degrees of applicability, at the same time that the hydriodate of potass is given. Then the prime remedy will often act as if there were no irritation.

The hydriodate of potass has a power over the liver similar to that of mercury and colchicum, but milder; and this power is based on a stimulation which it sets up in the duodenum. By what law is this effected? The question might be responded to by an analogy the most perfect, and with undeviating confidence, but that there are invisible lovers of science*, who, interfering in what they are intended by nature not to understand, the limits of their reason being assigned, are doomed in their narrow sphere to consider hypothesis as inimical to philosophy. Still it may be stated why the stimulation of hydriodate of potass in the duodenum, like that of mercury, colchicum, and other agents, is productive of a flow of bile. It is by an admirable deception of nature!

When the chyme escapes from the stomach into the duodenum, it performs its part as the only natural stimulant of the intestine, and successfully solicits bile. But when, in the absence of chyme, artificial stimulants are resorted to, the biliary apparatus, unintelligent, still obeys the call, and there is an evacuation of gall greater or less in proportion to the degree of stimulation above or below that of nature, and according as the stimulus of chyme is simulated by the artificial agent employed.

The hydriodate of potass mildly simulates the power exerted over the liver by chyme.

And in what manner does this agent

affect the intestines as it passes through their channel?

The hydriodate of potass stimulates the lacteals, and thus simulates the action of chyle. Unendowed with intelligence, acting only through fixed laws, to them the stimulant is sufficient, and they are prepared to absorb. But though excited, they find no chyle.—it is the hydriodate of potass; and this they refuse to imbibe. Thus a very important result is obtained—the effort of absorption without the act; important, indeed, in mesenteric disease, where the functions are deeply compromised, but where exercise of organization may thus be incited.

Here it may be well to propose a question—one of a somewhat subtle nature—whether this exercise of the lacteals, without a flow of chyle through their tubes, or, if the expression be adapted, this action on *racinity*, has the same effect on the secretions as if actual absorption had occurred? Secretion is kept in a ratio with absorption by nervous sympathy; the increase or diminution of the one influences the other in like manner; therefore, since it is less the presence of absorbed fluids than the organic action which constitutes absorption, will not this artificial action of the *chyleless* lacteals produce an increased natural action of the secretions on the mucous surface?

The view which has been now suggested of a simulating power exercised by medicinal bodies, is worthy of being further developed, and considered in relation to the degrees of deviation from the natural standard of stimulation—that exercised by chyme and chyle, according to the agents employed. By the observation of our daily habits, we are informed of the stimulating power of almost all foreign bodies on the salivary glands; and although the intestinal structure and its dependencies are beyond our view, the analogy is perfectly extensible to them, and enables us, by a correct process of ratiocination, to assume that as the action of chyme is, so is that of mercury, on the liver; that those bodies whose action is on the lacteals have the same effect as chyle on those organs; and that these various actions on the same apparatus differ only in degree.

An instance which I witnessed may be here adduced to demonstrate the

* Vide the letter, "Z.," in the MEDICAL GAZETTE for Dec. 17.

similarity of action possessed by hydriodate of potass and mercury on the living body. A female had taken half a grain of calomel night and morning, in the form of Plummer's pill, and discontinued the medicine after a short period, without constitutional disorder having supervened. The hydriodate of potass succeeded its use, and in a few days induced salivation. But in another instance, swelling of the glands having been too suddenly attributed to hydriodate of potass, inasmuch as the tumefaction subsided under its continued administration, it was thought proper, in the former case, to continue the medicine; but salivation rapidly increased, and was alleviated only when the hydriodate was withheld.

A metastasis of the tonic and stimulant action of hydriodate of potass to various organs may result from its continued administration. The stomach, probably the œsophagus, as well as the intestines, may be made subservient to the transmission of its effects. In these parts the local action must be stimulant before new power can be imparted through them to tissues which are remote, and connected less, if at all, by continuity, than by a medium of nervous fibres. In thickening of structure, such as is found in the mucous tegument of bronchial tubes, there is a certain degree of stony; that is, the circulation in the part is retarded by the condensed state of the tissue, and there is little advance made by its absorbent and excretory vessels. In this dilemma the stimulus of hydriodate of potass, urged from the stomach to the bronchial membrane, is not at first stimulant at its final destination, but tonic; nor until a higher vitality becomes established, is a stimulation induced in the thickened structure. This, however, being once accomplished, that is, the action of natural tonicity being exceeded, the absorbents will begin their task of carrying off the superabundant particles which constitute thickening; secretion follows; the blood is freely oxygenized, and the function of animal temperature restored.

And by what means are the absorbents thus induced to act? Before, unable to restore the condensed tissue to a normal state, they became insensible to the stimulus of particles which it should have

organic relations; an artificial stimulus renews their tone,—they experience extraordinary power. Organic particles, bordering on the transition state from solid to fluid, are the stimuli of absorbents attached to tissues for their gradual removal; the hydriodate of potass stimulates through nervous media these stimuli; the exercise of the absorbents gives these vessels strength, which, if at first ineffectual, is finally sufficient to break down the organization, and convey the detritus into the circulation.

Thus is established a new confirmation of the truth, that medicine in its successful action is an imitator of nature, the stimulus of the substance in question on the absorbents being similar in kind, although not in degree, to that of solid particles about to be removed by them from a healthy tissue. In the same way as it acts on the duodenum with a power like that of chyme, and deceives the intestines with a chyle-like action, it simulates the natural stimuli of absorbent vessels.

But what is to be brought forward hereafter as a principal means of curing certain diseases with the hydriodate of potass, may be here alluded to as accessory to its constitutional effects,—the power of carrying off bile from the system, and by opening the duct, of causing a free passage for the elements of diseased structure which the absorbents may have added to the blood.

By tracing the symptoms which hydriodate of potass produces on a living body, we are only tracing the direction and distribution of nervous fibres, and determining, by the simplest process of discovery, the manner in which it acts. For instance, in hysterical subjects, instead of fulfilling, as intended, any particular indication, it will act as soon as swallowed on the stomachic, and probably the œsophageal branches of the pneumo-gastric nerve; and spending its power on the superior laryngeal and the adjacent nerves, produce globus hystericus, which will continue sometimes for several hours.

Moreover, in tracing these symptoms in comparison with the disease existing, we obtain a still higher confirmation of the truth. A person with enlarged prostate, having taken hydriodate of potass, felt, after a reasonable time, a constant and plunging pain in the

tended along the line of the perineum, striking the prostate, and the extremity of the penis and rectum. Again, the bearing-down pains and others connected with the uterus which are attended by pain in the sacrum, may be removed by hydriodate of potass.

These two instances show that the branches of the hypogastric plexus and sacral nerves which are distributed at the colon and rectum may equally be attacked in those parts by an hydriodate, with a view to the relief of diseases which are under the control of its final distribution.

And the manner in which the indication is fulfilled is this:—A pain in the spinal cord is expressive of increased action, which art or nature may produce. In either case the new energy is given to nerves proceeding from the seat of excitation to its disordered viscus, to establish in the latter a process of cure. The hydriodate of potass, stimulating the spine through the nerves which acknowledge its source, and at the same time acting in like manner on the hypogastric plexus, the two-fold effect is conveyed to the terminations of the united nerves.

In the first of these cases, that of diseased prostate, the action is set up; in the second it is made complete.

It is the desire of the author to illustrate these theories by the cases on which they are founded, in a succeeding paper.

CORRECTION OF AN ERROR IN THE NEW PHARMACOPŒIA.

To the Editor of the Medical Gazette.

SIR,

MAY I beg that you will insert, in the next number of your journal, the following correction of a very palpable error in the formula for the extemporaneous preparation of hydrocyanic acid, introduced into the new edition of the Pharmacopœia Londinensis? I am indebted for its detection to Mr. Thomas Henry, operative chemist, of Great Ormond-street.—I am, sir,

Your obedient servant,

C. H.

ANALYSES AND NOTICES OF BOOKS.

“L'Auteur se tue à allonger ce que le lecteur se tue à abrégier.”—D'ALEMBERT.

A Practical Treatise on the Management and Diseases of Children. By R. T. EVANSON, M.D., and H. MAUNSELL, M.D., Professors in the Royal College of Surgeons, Dublin.

THE lack of good scientific books on children's diseases in this country, has long been felt by practitioners, young and old, and might well have formed a ground of reproach to British medicine, if there were not other topics fully as strong, and probably more obvious, to be urged by our continental brethren. Both in France and Germany, great attention has been paid to the subject, and in the latter country there are periodical works regularly established for the publication of papers on the diseases of infants, and their proper modes of treatment. Two of these we announced not long since, among our notices of recent German works. But we hope, nay, we think there are symptoms of it, that this unseemly defect in our medical literature will be gradually supplied. The volume before us is more than an earnest of a better order of things.

The authors have had ample opportunity of acquiring experience on the subject about which they have written, and, as it seems to us, they have profited by the occasion. Their book bears intrinsic evidence of the fruits of careful observation; it is judiciously and skilfully drawn up, and exhibits the joint production of the fellow-labourers in a very attractive light.

Dr. Evanson treats of the peculiarities of the infant structure and constitution, of infant pathology and therapeutics, of the diseases of the digestive organs and the brain, &c.; while Dr. Maunsell considers the physical education of infants, the accidents and diseases peculiar to new-born children, diseases of the respiratory organs, vacci-

eruptive fevers, and constitutional diseases occurring during the period.

It be seen that the range of text is extensive: we can safely add, it is wrought out diligently in art. The volume is compendious, it must not be confounded with those Mothers' Guides and Nurses' Measures which make their mistakes, or at least good-for-nothing, once from time to time. It assumes a scientific character, and we are not will be found useful by all who have to grapple with the difficulties of practice.

Description of the Bones, for Students in Anatomy. By J. F. SOUTH, Assistant-Surgeon to St. Thomas's Hospital. Third edition.

This new edition is rendered far superior to its predecessors, by being richly illustrated with wood engravings interwoven with the letter-press. We think it will be one of the best manuals of anatomy for the student.

DICAL GAZETTE.

Saturday, December 31, 1836.

"omnibus, licet etiam mihi, dignitatem
licet tueri; potestas modo veniendi in
est, dicendi periculum non recuso."

CICERO.

CORPS D'ELITE OF THE NEW UNIVERSITY.

Last week pointed out our objections to one of the most conspicuous features of the new University — that which places all educational control in the hands of the Minister, — and management the more extraordinary from an administration who have their claims to public favour on the liberality of their politics. This most un-English regulation the worst feature is the spirit already evinced, and we add, the injustice displayed, in many existing schools, — two being named in the charter, al-

though the right of others to a like distinction was admitted in certain speeches, which, though possibly forgotten by the orators, are — thanks to Hansard — not lost to the world.

True, we are told that other establishments may be added hereafter; but why was this not done at once? Why is an equality in this respect not given to all who equally deserve it? Why are others to sue, cap in hand, for that which is conceded without question to two institutions? The answer is quite obvious: to favour that establishment, which enjoys the patronage of the government. But it may, perhaps, be said, the ministers did not know of any other schools worthy to be so honoured. Now our business is with medicine; and we say in reply, that, with regard to our profession, they *did* know of others; that they *were* aware of the existence of numerous medical schools as good as those selected; and that this knowledge resulted from their having put the teachers in those schools to an immense deal of trouble, and to the expense of 450*l.*, to make good their rights before the Privy Council. In words and speeches the ministers at length acknowledged those rights, — and acknowledged only to disregard them. When Mr. Tooke made a motion, praying his Majesty to bestow a charter on University College, Lord John Russell, in his place in the House of Commons, observed, that "he (Lord John Russell) had been present at that Council. * * * The great objection appeared to him, and he believed all the Council thought so, to be not so much on the part of the two Universities, as on the part of the medical schools of London, and he thought that the other schools of London would be entitled to confer medical degrees, if that power was given to the University of London*." Such were the words then

* Hansard, Vol. xvii. p. 299.

used by the Secretary of State for the Home Department; and we leave it for our readers to judge how far they are consistent with the omission from the charter of every one of the medical schools whose merits he thus acknowledged.

It is necessary to lay down certain regulations as to the period and manner of study suited to the average capabilities of human intellect; and it is proper to take care that the means requisite for acquiring knowledge shall have been enjoyed; but beyond this all should be free and uncontrolled. Certain of the larger and more influential schools of medicine, as a matter of course, will be admitted, were it only for the sake of decency; but with some not less deserving it will probably be otherwise; and thus a most objectionable system of preference and patronage take the place of free and open competition.

Again: of the men chosen to carry this compound of radicalism and oppression into the walks of science, we remarked last week, that all we could say of them (with a few exceptions) was, that they were *respectable*; and we cannot, on reflection, find any epithet more applicable to their general standard of scientific or professional acquirement. With regard to some of the appointments, we are not aware that any rational explanation can be offered: the parties may thank their stars, and say with Malvolio, "Well, 'tis Jove's doing;" or they may perhaps remark, on the same authority, that "some are born to greatness."

Several of the nominations, however, are very easily accounted for. We have four or five physicians who entailed a debt of gratitude on the Chairman of the Medical Parliamentary Committee, by the unmitigated bitterness of the evidence they gave against their own College; at least if this be not the cause of their selection, we confess ourselves

at a loss to offer any feasible conjecture on the subject. Here there is an obvious connexion between the cause and the effect; and this illustrates the second mode of advancement—for "some achieve greatness." One respected physician, holding a high professional office under government, we are assured became a "senator" upon compulsion, and another, the best known of all in the paths of science, had his name inserted without the preliminary courtesy of asking his permission! Nor is this a solitary case; and here we have illustrations of Malvolio's third mode of advancement—for "some have greatness thrust upon them."

We do not wish to say any thing wantonly to hurt the feelings of the gentlemen in this department, but the plain truth is, that there is not one pre-eminent man among them, and of the two or three who enjoy any distinction, this has been acquired in some other branch (as natural history, or natural philosophy), and not in the teaching or in the practice of their own profession.

But if the new University be weak in physic, what are we to say of the other departments? What names renowned in surgery are to grace the embryo diplomas? Who are the illustrious men who have been selected to counterbalance the fame of the College in Lincoln's-Inn? Let the profession hear, and mark it with admiration. They are Sir S. L. Hammick and Mr. Kiernan. The name of the former may possibly be known to our readers, as we announced his elevation to the baronetage a few years ago. An injudicious friend of this gentleman, who has written in defence of his appointment, tells us that he has performed the operation of amputation two hundred and eighty times! Without disputing the accuracy of an informant so intimately acquainted with the details, we take leave to ask him whether, if

Mr. Hammick had not happened to attend Lord Grey's family during their residence at Plymouth, it is probable that he would now have been either a baronet or a "senator," even if he had cut off the arms, as well as the legs, of the 280 persons whose limbs he amputated?

The name of the latter gentleman (Mr. Kiernan) cannot, we are sure, be forgotten, as that of an ingenious young anatomist, whose papers on the liver have deserved and received our warm commendation; but whose name is yet wholly unknown in surgery.

And could no other surgeon be found, to give something like respectability to this department of the University—none to save it from mere mockery? In London there was none; no English surgeon, who had a name or reputation to lose, would hazard either; but Ireland had "our well-beloved Surgeon-General! Philip Crampton, Doctor in Laws." Did Mr. Crampton know that he was applied to as a *dernier ressort*, because all of his own rank here declined? Are his prospects in Dublin so reduced that he will come to London, on the strength of an appointment which none of his compeers here could be prevailed upon to accept; or is it the plan that he shall not be required to visit the metropolis, but have the diplomas sent to him like bills of exchange, for the benefit of his signature? We would strongly recommend this last arrangement, as the safest to be adopted; for though we readily admit that he is a distinguished surgeon, yet he may rest assured, nevertheless, that the "General of the Laureates" is much better known in the Irish metropolis than here.

* The Surgeon-General is, or was, in the habit of going to the Lord Lieutenant's levees in a splendid military uniform. On one of these occasions, Lord Norbury, observing him pushing his way, with some difficulty, through the crowd, cried out, "Make way, there, make way for the General of the Laureates!"

When a young man has been educated as a surgeon in London, and has passed the ordeal at Lincoln's-Inn Fields, he carries with him a document which commands respect, in whatever part of the civilized world his destinies may carry him. What is this owing to? Simply to the names attached to his diploma—to the signatures of Cooper and Brodie, of Lawrence and Travers, of Green, of Keate, of Guthrie, and others of scarcely inferior note. No proof of this is necessary, but we give the following anecdote, because it is a striking illustration of our argument.—In the early part of the present civil war in Spain, a young English surgeon presented himself in the Carlist army, then pent up among the mountains of Navarre. He was wholly unknown, and had no voucher of any kind but his surgical diploma. Zumalacarréguy saw the name "Asley Paston Cooper" attached to it, and appointed him without further inquiry to be a surgeon on his staff. We should like to know if the whole list of Senators of the new University, from Lord Burlington downwards, would have done as much for him?

But there is yet another branch in the medical department of the University: Messrs. Bacot and Ridout, two of the examiners at Apothecaries' Hall, are Fellows and fellow "Senators." We attribute their nomination to a piece of skilful generalship on the part of Mr. Warburton. The Colleges of Physicians and Surgeons would not be seduced; but we understand that he flattered the Apothecaries into acquiescence. The gentlemen above named are wise, too, in their generation; for if the University succeed, their former occupation will be gone; and if it fail, they have only to retreat again to their brethren at Blackfriars. But for the other members of the Worshipful Society, what are *they* about?—are they dragged

with their own opium, not to perceive that the success of the University must be their destruction? The College of Physicians has some *prestige*—the College of Surgeons some reputation; both have the magic of a name to support them; but what have they of the “Hall” to trust to? If their chairman and most *redoubted* examiner concur in conferring diplomas at another Board, which carry with them the Doctorate, who, think they, will apply to them for an *untitled* license?

As three surgeons were appointed, so also were there three general practitioners; the third being no less a person than the fashionable apothecary who attends the present Premier and several of his colleagues. Mr. Pennington —; but he has had the good sense to direct that his name may be withdrawn.

We have neither heard of, nor can discover, in the selection of the “Senators,” any one avowed or ostensible principle which is not violated. Thus the absence of the names of those best fitted for the task of Examiners is attributed to a determination to admit no one actually engaged in teaching; and this with a view of securing impartiality. Yet Mr. Faraday teaches at one school, and Mr. Brande at two! Again, the same motive is assigned for the exclusion of those connected with hospitals; but to this an exception is made in favour of Dr. Billing,—for what reason, does not appear on the record. In fact, the only principle consistently followed out is that of placing on the senate the greatest possible number of persons connected with University College, Gower-Street,—and this also, doubtless, with the view of securing impartiality.

Neither are the blunders which have been made in the names and designations of the members of the Senate less remarkable. Several of them are wrong

spelt; two Fellows of the College of Physicians are robbed of that distinction, while it is bestowed on two others to whom it does not belong; nay, in one instance a surgeon is mistaken for a physician, and assigned to the wrong College; although it is now in evidence that he has amputated more limbs than the Body in question has members. In fact, it is difficult, in reading over the names, to say which is most calculated to excite admiration—the excellence of the selection, the correctness of the designations, or the felicity of the orthography.

Here, then, we enter our protest. Nothing would have given us more gratification than to have seen a medical institution on really liberal principles, by which the *summi honores* should have been open to all, without the necessity of leaving the metropolis. But the new University is only calculated to remove the distinctions in the profession, by “levelling downwards.” It is an embodying of the “One Faculty” chimera, by which all grades are to be done away, and consequently the chief motive to exertion destroyed. It is a blind and stupid confounding of the aristocracy of intellect with aristocracy of birth; as if the same reasoning applied to each;—and so far as its influence may extend, it is to secure to mediocrity the same rank as to the highest attainments. It is to throw down the torch of discord between the existing corporate bodies and the new—between the alumni of the one and the graduates of the other. And while in principle it combines democratic professions with an arbitrary subjection of science to political power, it establishes a system calculated to ruin many of those now engaged in teaching, and to give a shock to the whole fabric of education in this country, the effects of which years may not be sufficient to undo.

ATTENT OF MEDICAL WITNESSES UNDER "WAKLEY'S TEST."

I have not room this week for any remarks on the subject to which the foregoing letter relates, but shall take an opportunity of placing in its true light the conduct both of Wakley and his very obedient servant," the coroner at Southwark. Meantime Mr Aldred will not be prevented from expressing his opinion of the worthy pair.

The Editor of the Medical Gazette.

SIR,

Your letter appeared in the *Lancet* of last month, from Mr. Ferrier, the Coroner of Southwark, attempting to explain his conduct. I shall take no notice of any insinuations, but will pledge myself to prove the correctness of my statements, and the falsehood of his, should mine be denied by any person whose word I can place the least test reliance; but it would be like arguing with a shadow to reply to any said or written by such a person. His malignant observations upon lithotomy case, I have merely to observe, that I acted by the advice of much more and more experienced surgeons than Mr. Ferrier (who, by the by, has been in practice seven years longer than the person he designates the *very good practitioner*). Before concluding I beg to assure Mr. Wakley that he will not vent his low abuse and slang upon me as long as he likes, as I consider his character as much upon a par with that of his correspondent Mr. Aldred.—I remain, sir,

Your obedient servant,

CHAS. C. ALDRED.

Southwark, Norfolk,
Dec. 26, 1836.

CLINICAL LECTURE,

Delivered at St. George's Hospital, December 16, 1836,

By DR. SEYMOUR.

ORGANIC DISEASE OF THE STOMACH.

There are not many cases in the hospital present respecting which I wish to ad-

dress you; I will, however, notice one or two—one in particular, because I spoke of it in the second of this course of lectures, and it has issued precisely in the manner which I expected it would do when we first considered it.

It is the case of a man named WILSON, and you may remember that I spoke of him as labouring under organic disease of the stomach*. I told you that there was a tumor situated midway between the umbilicus and the superior anterior spine of the ilium, on the left side. I mentioned that we not unfrequently found the stomach pushed down in this direction, and the pylorus being thickened externally, it gave the appearance of a tumor. After a little time the pain which this man suffered in the tumor was greatly relieved by the application of leeches, and subsequently it disappeared altogether. This led some gentlemen to doubt how far the diagnosis was a just one; but the man's appearance, the water-brash, and the certainty of the tumor in the first instance, always made me feel satisfied that the complaint still remained. The fact is, he lay in or on the bed for some successive weeks, and the tumor not adhering to the parietes of the abdomen, the stomach changed its position, and the tumor disappeared.

For a short time he was so well, that I thought it very likely that he would not remain much longer in the hospital. All the symptoms were quiet until the 28th of last month, when he began to be attacked with a very remarkable kind of fever, a fever evidently denoting that suppuration was going on in some internal organ. There was a violent accession of heat; shivering followed by heat, and sweating to a very great degree; and as this diminished, there were all the symptoms of that great disturbance of function which is termed *typhus fever*—*low fever*. There was a dry dark tongue, subsultus tendinum, especially in the muscles of the face, and occasional vomiting. It was quite obvious that this was a token of a very considerable degree of disturbance going on in the system, and of the internal disease having taken on some accession.

When this had continued about a week he died; and, upon opening the body, we found that about one inch above the pylorus was a tumor about the size of a pigeon's egg, and which was attached to the coats of the stomach. The coats of the stomach around that part were greatly thickened, and in one portion were so accumulated as to contain, in a depression

* Vide MEDICAL GAZETTE, No. 465, p. 151.

formed by the thickened coats, a space about sufficient to enable you to place in it a walnut. In addition to this, a tumor of the same kind was seen attached to the cellular membrane of the pancreas, which, upon being cut into, was soft, as if it were undergoing an operation similar to suppuration. A part of this which was still hard presented a melanotic appearance, shewing evidently the malignant and cancerous nature of the disease. I have no doubt, from the changes which took place in the large tumor, that during life it was the size of a hen's egg. This cause gave rise to a set of symptoms which would have been called, if no internal disease had been visible, a case of *tubercle*. You are to remember that the same symptoms would have been set up from inflammation of the brain, from inflammation and ulceration of the bladder, from inflammation and rapid ulceration of the small intestines, or any other rapid lesion of an internal structure, the due performance of the functions of which is necessary to life.

HYSTERIA.

The next case respecting which I mean to speak, and which I shall take an opportunity of doing in this lecture, is that of VAUGHAN, who came in labouring under rheumatism*. Subsequently to her getting well of that complaint she had a violent attack of that form of disease termed *hysteria*. Even when she was cured of the rheumatism the nervous system was in a state so easily admitting of being disturbed, that it was quite impossible to send the poor woman back to her labour; at the same time there was no great disease—certainly no disease of structure; nothing but a general derangement of function remaining. This case will lead me to speak of hysteria in general.

It is of great importance in a practical point of view, to know the real disease from that which may be called, under particular circumstances, the *simulated* disease. Everybody knows what an hysterical fit is. The patient complains of something rising up into the throat like a ball, which cannot be swallowed; this is usually followed by a convulsive motion of the muscles, often of the trunk and of the face, accompanied with laughing, crying, screaming, and violent efforts to swallow at the same time, but always an alternation of crying and laughing. This is termed an *hysterical paroxysm*. Nothing can be more common than this; but you

are not to suppose that hysteria stops here.

One of the great masters of our art, Sydenham, who once enjoyed considerable practice, and who still possesses great reputation in the medical world, says that the changes of this particular disease are more variable than the hues of the chameleon. But it sometimes takes on, or simulates, all the appearances of inflammatory disease in different viscera of the body. It not only does this, but it gives rise to a train of symptoms, or mental disorder as it may be called, which leads the patient to practise imposition. I know nothing more difficult, or more necessary, than to endeavour to distinguish between these two diseases, because in the one case you may do a great deal of good, and in the other you may really kill the patient—by overlooking a real inflammatory state, on the one hand, or taking an hysterical state for inflammation, on the other.

I stated that everyone knows what an hysterical fit is; but there is another set of symptoms which accompanies this condition of the body. There may be pain over one eye, and you can cover the part affected with your finger; this is termed *clonus hysterica*. Sometimes there is pain in the hypochondria, but it most frequently occurs on the left side; and hence it has been supposed to arise from the vapours of the spleen, especially if in such circumstances the patient is low-spirited and fantastical. You will find it spoken of in books, and you will hear persons talk, as if the patient were labouring under vapours of the spleen—a sort of hysterical condition. But although the pain is a most remarkable symptom, it may be doubted whether it arises from that source. Patients are often troubled with flatulence; and some persons believe that where the left hypochondrium is affected, it arises from wind in the stomach; and where the right hypochondrium suffers, that the wind is collected in the upper part of the abdomen. In either case, however, it is simply a symptom, and is to be taken together with the other symptoms of the complaint. I do assure you, that scarcely a week elapses in which I do not see cases where these symptoms have been treated as symptoms of acute disease. Because acute inflammation of the liver, or the spleen, is laid down in books as productive of pain in the right or left hypochondrium, increased on pressure, and because the patient in hysteria complains of pain increased on pressure, it is therefore concluded that she labours under one of the former complaints. But in hysteria

* Vide MEDICAL GAZETTE, No. 464, p. 117.

the pain is so increased, that no inflammation except the gentlest form could give rise to so much suffering when she is touched. The patient's health is sometimes not affected, or if affected, it is in a dilapidated condition. In general, though not always, the menstrual discharge is irregular; it is too much, or, which occurs more frequently, too little; or it does not take place at the natural periods. You have, then, this second form of the disease.

But hysterical paroxysms will come on in such a condition of the body as this, of the most alarming kind. The patient will be for hours together with the back bent, as in opisthotonos, with the teeth clenched, and the hands and fingers drawn in. At other times there will be great difficulty of swallowing, and at others great difficulty in passing water; and this is very commonly the case in hysterical women.

The next form of the disease is where the mind seems to be still more affected than the body, with this general derangement and nervous sensation. The patient will try to persuade the practitioner that she has real disease. Hence the cases which occur of sand and gravel being presented as having been passed from the bladder, such sand and gravel as you know could not originate in an animal body; very different secretions from what take place there. At other times stones, and even flint stones, are shewn, and are said to have been passed from the bladder. Such cases, although I do not mean to say that they are the most common things in the world, are by no means uncommon. There is scarcely a physician of any practice in this town who has not seen cases of this kind. At other times the patient will eat nothing. I saw a young lady who for several months had taken nothing but half a cupful of tea two or three times a day, and in this condition there were hysterical fits almost amounting to epilepsy.

You have, therefore, in the treatment of this disease a great deal to which to attend. In the first place, knowing as you do that a great number of these cases are simulated, you are to be firm in your treatment, not to be biased on one side or the other by persons coming and giving you their advice. You have at the same time to be very firm with the patient; but take care that you do not disgust her by laughing at her, or ridiculing her, for she will in that case imagine that you cannot cure the disease, and she will send for some one else who is more credulous or patient. You must hold a tight rein, insisting upon that being done which is necessary, and

stating to the family that in the end the patient will recover if such means be put in practice. But it often requires a very great deal of care and attention in order to effect this. Sometimes there is even vomiting of blood: this occurs in this very patient. There is sometimes hysterical palsy in the lower extremities. I saw a case of hysterical palsy which occurred in a servant. She had been very laboriously exercised, her health had given way, and she had palsy of the lower extremities. She had been bled four times, and had had on eleven blisters. When I saw her there was a want of due circulation, blisters arose on her extremities, her back sloughed, and she died in consequence of it. Now this was not an imaginary case. I will tell you one instance which occurred lately, and where the treatment was successful, and therefore it is a much more important case. A very young lady, and of uncommonly active appearance, had three or four years ago a fall from a horse. It was said that she sustained concussion of the brain. I mention this to show that the case was complicated. She had been well for three years, and the blow might have been forgotten, as if it had not happened. Latterly, however, she had become exceedingly ill: there was pain in the head, pain in the back, globos hysterici, and towards the evening there came on a violent fit, resembling very much something between epilepsy and hysteria. She was abroad at the time. She was cupped, bled, put on a course of mercury, and had moxæ applied all down the spine. She was then brought to England that a physician might attend her here, and she came to town. I have seen her for three hours bent like an arch, with her feet behind, her hands clenched, her teeth shut, exhibiting the strongest instance of what is called toxic spasm which I ever saw in my life, as bad as you see represented in pictures of tetanus. Yet all this went off with the hysterical fit: it was neither more nor less than hysteria. On one occasion I was sent for to see her, and I did what I cannot recommend you to do: disregarding inconvenience altogether, I poured pail after pail of water upon her as she lay on the bed, and then forced her to drink a large quantity of sal volatile. Then came the trial of getting her to take food; for the patient always sets herself against it: it is not that she cannot take it, but she will not. She was then ordered a drachm of asafoetida, an ounce of lime water, and half an ounce of pimento water, to be given two or three times a day. It is exceedingly nasty, no doubt, but it has an effect of which you

really have no idea. This patient was given a combination of conium and galbanum as well as asafœtida. By degrees she got better, the paroxysm which used to come on at six o'clock in the afternoon went off, and then came a spasmodic shutting of the eyelids. That likewise left her, and then she was able to stand. But I should tell you that when the case was first brought to England the whole of the lower extremities had entirely lost their motion, and very nearly their sensation. This, combined with the fact of the blow, the cupping, and the application to the spine of such an abundance of blisters and moxæ, would render the case very complex. Still, from the circumstance of the patient's general appearance and good health, with her quietness when not in a paroxysm, her age, and the irregularity of the uterine discharge, I entertained no doubt of her condition, and the young lady is now perfectly well. Before she went out of town I requested that Sir B. Brodie might see her, because, if there should be any return, persons might persuade her friends—and they might be themselves mistaken—that she was suffering from disease of the spine. He accordingly examined the spine, and it was in a perfectly good condition; but at the same time the appearance of the scars on this part of the body, which had been produced by the severe treatment she suffered abroad, was quite extraordinary. I have not the least hesitation in saying that every one of the measures adopted was unnecessary,—that every one aggravated the disease, so that she nearly fell a victim to them. Hence you see the great necessity of understanding well what may be called *apparent* disease, in contradistinction to that which arises from a *real* affection. Unfortunately the patient often has pain in the right or left hypochondrium; and when it occurs on the right side, it has been called *hypatalgia*. This pain, if it were really arising from an inflammatory condition of the structures, would be attended with a febrile pulse, with a foul tongue, with great disturbance, and great depression of strength; but it is not attended with any one of these symptoms; and though the tongue may be more or less white, and the pulse weak, yet the patient bears the application of pressure, and has her usual appearance.

Sometimes the disease affects the breast in such a way as to cause it to be tumid. I saw myself a young married woman, who had no family, who, at every period of the menstrual discharge, had such violent pain in the breast, and such violent hysterical fits, that it was sometimes

thought that she would not survive the night. This was entirely cured by asafœtida. There was a case in the hospital, some years ago, of a woman named Osmond, who made a great deal of noise in the world. She had been in love, and was in a disposition of mind disposing her to an hysterical diathesis. It was said that she had taken laudanum, but I could not make that out. When she was brought into the house she was paralytic in the lower extremities, and remained so for some months. None of the ordinary remedies were of any use in removing the palsy,—neither bleeding nor blistering, nor any kind of counter-irritation. They were tried, but in vain, because I did not then know that the disease went to such an extent as to simulate so severe a complaint as actual palsy of the lower extremities. At length I put her on asafœtida, and asafœtida alone; I gave it her at night in pills, and in mixture by day, and kept her quiet. By degrees she began to recover the use of her limbs, and I then ordered the shower-bath, which is an exceedingly useful adjunct in this complaint, and she recovered. She went out of the hospital; she has since married and borne two children, and has never had any return of the disease. There was another case which made a great noise some years ago, of a young lady who could not swallow any thing in consequence of a sort of spasmodic action. A number of observations were published on the case. She recovered by the constant use of cold affusion, pouring cold water upon her—(and such cases, in point of fact, you frequently meet with)—followed by rubbing in a drachm of belladonna every two hours, and lin. camphoræ compositum. You will remember a woman in Roseberry Ward, with an hysterical affection, which caused her to walk on one side, to whom we applied this remedy, and who got manifestly better. She had not been long in the hospital when she went out, having been in one hospital before. I believe she went out because she was getting better, and we were controlling the disease. It was not quite her cue to get well, and I have no doubt she would go to another hospital.

The most extraordinary part of this business is the imposition which females will practise in such circumstances. There was a woman in the hospital who had constant vomiting, but there were none of the symptoms usually accompanying it—no real disease of the stomach, no real disease of the brain, and no real disease of the lungs; and yet she vomited every thing she took. I had her very narrowly

, and it was found that her friends gave her opium, which she took in order to produce this vomiting, and to her surprise. This was a case purely artificial. In private life you will find persons who under other circumstances would disdain a falsehood or a lie, who will practise similar deception. I attended a young lady, who took opium mixed with something else, to procure violent spasmodic vomiting every day.

Are we to call the state of mind which the patient labours when it is of this extent? It would be called hysteria; and yet it certainly depends on an irregular condition of the nervous system of which I have been speaking.

A great peculiarity of mind—this artificial diathesis—will be cured by the action on your part; by checking if too full, or by restoring if deficient, the natural discharge, and the use of those remedies to which I have adverted—i.e. opium, galbanum, castor, and preparation of ammonia, such as spirits and oil of ammonia. Ten or twelve years ago I was very much struck with a case of hysteria, which occurred in a young lady 17 years of age. I had attended her when she was some months before, from which she recovered. She complained of a pain in the right side, and it was indeed there; her tongue was loaded, she was a person apparently of no strength of body, and the pulse was small. There were all the symptoms laid down in books as indicative of derangement of the liver—such as pain in the right side, rising up to the shoulder, and distention to food. I had her bleed, gave her opium and saline medicines,—treated her as if she laboured under hepatic disease, but she laboured under hysteria, for which that disease will often be mistaken. She became no better, and I gave her larger doses of medicine which she refused to take, the more constipated her bowels became. This is a very common symptom in young ladies labouring under hysteria, they bear such large doses of medicine, that you are astonished how persons, otherwise so delicate, can require such purgative medicine before a motion is produced. When this occurs to you, be assured that there is no other such violent means—more moderate, repeated at proper intervals, succeed when the disordered condition of the nervous system throughout the body has been removed. Her bowels were constipated, and at length she began to have great difficulty in making water, and I had a suspicion that it was one of

those diseases which we see every day of our lives in a hospital. The course was altered: I gave her some aloetic pills with myrrh, and ordered the shower-bath. The pain in the hypochondrium disappeared, and she got well. I have mentioned the case because it is instructive to you, as pointing out, that whenever you see a young person with this particular form of complaint, unless there be other symptoms, such as disturbance of the natural and vital functions, tallying, as it were, with the great severity of the pain, whether in the side, the head, or the chest, you should doubt whether it is not one of those irregular cases in which, in order to cure the state, you should strengthen the nervous system, rather than resort to those ordinary methods of treatment adapted to inflammation situated in the viscera.

When a patient has gone so far, it is astonishing how she will sometimes recover. I assure you that I do not exaggerate when I tell you that I have seen case after case of this sort. I saw a young lady recover who had been pronounced by one of the most competent authorities to be labouring under abscess of the brain. She recovered by means of tonic medicine, by nutritious food, beginning by degrees, and then riding on horseback. She is now quite well. Suppose she had been treated by the urgent symptoms only, by lowering that state of the system which appeared to be set up by structural disease, undoubtedly the patient would have died.

In the present case—that of Vaughan—she was put on asafetida on the 5th November. She had some slight return of the rheumatism, which was obliged to be cured; but in this instance the rheumatism was so masked by the hysteria that I gave her opium, and opium alone; of which she took a grain every two hours. The rheumatism being removed, she then returned to the asafetida, and I have no doubt that she will ultimately recover. It is very uncommon for us not to have two or three such cases in the house.

The best treatment, where a patient has a difficulty in walking up stairs, is a drachm of ammonia and tincture of valerian, placing in the shower bath, and giving her good diet and rest. The cases which we see in the hospital are generally those of young women who have been overworked—servants of all-work, or milliners' apprentices, or ladies' maids, who sit up at night for their mistress, and then lie in bed till she gets up, which is generally twelve or one in the day, and who get no sort of exercise. They labour under all those diseases which affect the higher classes of life, and

really have no idea. This patient was given a combination of conium and galbanum as well as asafoetida. By degrees she got better, the paroxysm which used to come on at six o'clock in the afternoon went off, and then came a spasmodic shutting of the eyelids. That likewise left her, and then she was able to stand. But I should tell you that when the case was first brought to England the whole of the lower extremities had entirely lost their motion, and very nearly their sensation. This, combined with the fact of the blow, the cupping, and the application to the spine of such an abundance of blisters and moxa, would render the case very complex. Still, from the circumstance of the patient's general appearance and good health, with her quietness when not in a paroxysm, her age, and the irregularity of the uterine discharge, I entertained no doubt of her condition, and the young lady is now perfectly well. Before she went out of town I requested that Sir B. Brodie might see her, because, if there should be any return, persons might persuade her friends—and they might be themselves mistaken—that she was suffering from disease of the spine. He accordingly examined the spine, and it was in a perfectly good condition; but at the same time the appearance of the scars on this part of the body, which had been produced by the severe treatment she suffered abroad, was quite extraordinary. I have not the least hesitation in saying that every one of the measures adopted was unnecessary,—that every one aggravated the disease, so that she nearly fell a victim to them. Hence you see the great necessity of understanding well what may be called *apparent* disease, in contradistinction to that which arises from a *real* affection. Unfortunately the patient often has pain in the right or left hypochondrium; and when it occurs on the right side, it has been called *hypatalgia*. This pain, if it were really arising from an inflammatory condition of the structures, would be attended with a febrile pulse, with a foul tongue, with great disturbance, and great depression of strength; but it is not attended with any one of these symptoms; and though the tongue may be more or less white, and the pulse weak, yet the patient bears the application of pressure, and has her usual appearance.

Sometimes the disease affects the breast in such a way as to cause it to be tumid. I saw myself a young married woman, who had no family, who, at every period of the menstrual discharge, had such violent pain in the breast, and such violent hysterical fits, that it was sometimes

thought that she would not survive the night. This was entirely cured by asafoetida. There was a case in the hospital, some years ago, of a woman named Osmond, who made a great deal of noise in the world. She had been in love, and was in a disposition of mind disposing her to an hysterical diathesis. It was said that she had taken laudanum, but I could not make that out. When she was brought into the house she was paralytic in the lower extremities, and remained so for some months. None of the ordinary remedies were of any use in removing the palsy,—neither bleeding nor blistering, nor any kind of counter-irritation. They were tried, but in vain, because I did not then know that the disease went to such an extent as to simulate so severe a complaint as actual palsy of the lower extremities. At length I put her on asafoetida, and asafoetida alone; I gave it her at night in pills, and in mixture by day, and kept her quiet. By degrees she began to recover the use of her limbs, and I then ordered the shower-bath, which is an exceedingly useful adjunct in this complaint, and she recovered. She went out of the hospital; she has since married and borne two children, and has never had any return of the disease. There was another case which made a great noise some years ago, of a young lady who could not swallow any thing in consequence of a sort of spasmodic action. A number of observations were published on the case. She recovered by the constant use of cold affusion, pouring cold water upon her—(and such cases, in point of fact, you frequently meet with)—followed by rubbing in a drachm of belladonna every two hours, and lin. camphoræ compositum. You will remember a woman in Roseberry Ward, with an hysterical affection, which caused her to walk on one side, to whom we applied this remedy, and who got manifestly better. She had not been long in the hospital when she went out, having been in one hospital before. I believe she went out because she was getting better, and we were controlling the disease. It was not quite her cue to get well, and I have no doubt she would go to another hospital.

The most extraordinary part of this business is the imposition which females will practise in such circumstances. There was a woman in the hospital who had constant vomiting, but there were none of the symptoms usually accompanying it—no real disease of the stomach, no real disease of the brain, and no real disease of the lungs; and yet she vomited every thing she took. I had her very narrowly

watched, and it was found that her friends brought her opium, which she took in order to produce this vomiting, and to excite my surprise. This was a case purely of imposition. In private life you will meet with persons who under other circumstances would disdain a falsehood or imposition, who will practise similar deceptions. I attended a young lady, who took opium mixed with something else, to produce apparent violent spasmodic vomiting during the day.

What are we to call the state of mind under which the patient labours when it goes to this extent? It would be called *monomania*; and yet it certainly depends upon that irregular condition of the nervous system of which I have been speaking.

This great peculiarity of mind—this hysterical diathesis—will be cured by firmness on your part, by checking if too abundant, or by restoring if deficient, the catamenial discharge, and the use of those foetid gums to which I have adverted—*assafoetida*, *galbanum*, *castor*, and preparations of ammonia, such as spirits and tincture of ammonia. Ten or twelve years ago I was very much struck with a case of this kind, which occurred in a young lady about 18 years of age. I had attended her for the measles some months before, from which she recovered. She complained of constant pain in the right side, and it was very severe indeed; her tongue was loaded, and she was a person apparently of full habit of body, and the pulse was quick. There were all the symptoms laid down in books as indicative of derangement of the liver—such as pain in the side shooting up to the shoulder, and aversion to food. I had her bled, gave her calomel and saline medicines,—treated her as though she laboured under hepatitis, and under which that disease will ordinarily get well. She became no better, and the larger the doses of medicine which I gave, the more constipated her bowels appeared to become. This is a very common symptom in young ladies labouring under hysteria; they bear such large doses of medicine, that you are astonished how a person, otherwise so delicate, can require so much purgative medicine before a motion is produced. When this occurs to your mind, be assured that there is no occasion for such violent means—more moderate doses, repeated at proper intervals, will succeed when the disordered condition of the nervous system throughout the body has been removed. Her bowels were constipated, and at length she began to have great difficulty in making water. I then had a suspicion that it was one of

those diseases which we see every day of our lives in a hospital. The course was altered. I gave her some aloetic pills with myrrh, and ordered the shower-bath. The pain in the hypochondrium disappeared, and she got well. I have mentioned the case because it is instructive to you, as pointing out, that wherever you see a young person with this particular form of complaint, unless there be other symptoms, such as disturbance of the natural and vital functions, tallying, as it were, with the great severity of the pain, whether in the side, the head, or the chest, you should doubt whether it is not one of those irregular cases in which, in order to cure the state, you should strengthen the nervous system, rather than resort to those ordinary methods of treatment adapted to inflammation situated in the viscera.

When a patient has gone so far, it is astonishing how she will sometimes recover. I assure you that I do not exaggerate when I tell you that I have seen case after case of this sort. I saw a young lady recover who had been pronounced by one of the most competent authorities to be labouring under abscess of the brain. She recovered by means of tonic medicine, by nutritious food, beginning by degrees, and then riding on horseback. She is now quite well. Suppose she had been treated by the urgent symptoms only, by lowering that state of the system which appeared to be set up by structural disease, undoubtedly the patient would have died.

In the present case—that of Vaughan—she was put on *assafoetida* on the 5th November. She had some slight return of the rheumatism, which was obliged to be cured; but in this instance the rheumatism was so masked by the hysteria that I gave her opium, and opium alone; of which she took a grain every two hours. The rheumatism being removed, she then returned to the *assafoetida*, and I have no doubt that she will ultimately recover. It is very uncommon for us not to have two or three such cases in the house.

The best treatment, where a patient has a difficulty in walking up stairs, is a drachm of ammonia and tincture of valerian, placing in the shower-bath, and giving her good diet and rest. The cases which we see in the hospital are generally those of young women who have been overworked—servants of all-work, or milliners' apprentices, or ladies' maids, who sit up at night for their mistresses, and then lie in bed till she gets up, which is generally twelve or one in the day, and who get no sort of exercise. They labour under all those diseases which affect the higher classes of life, and

this is one of the number. Soothe the patient well, and she will speedily get cured.

Supposing, however, that the disease is more severe—supposing there is some loss of power in the lower extremities, or severe pain in the hypochondrium—then you must have recourse to foetid drugs, and asafoetida is the best. The most remarkable part of the complaint is, that although patients at first are very naturally disgusted at the nauseousness of the foetor, yet it is astonishing how soon they get rid of it: after a short time, all the nauseousness of the remedy is taken away, and the patient clings to it—asks for it. The extraordinary use of foetid gums in this disease, has been asserted from the time of the great physicians, who attempted to explain their *modus operandi* by supposing that the uterus became swollen and rose from the pelvis, and that the odour of these gums caused it to return to its proper situation. This proves, however, the very imperfect knowledge of anatomy and physiology which the ancients possessed. They were in the habit of using odoriferous drugs in fumigation, to entice, and gave the foetid gums to drive the uterus back again. These complaints of a spasmodic nature, and disorders of function of the nervous system, were relieved, 2000 years ago, by those very remedies which are now employed; so that they have the test of experience, whether their mode of operation be well or ill explained. But it is a matter of great importance to remember that their use is confirmed by so many years' experience.

You should carefully consider these particular cases at the bedside of the patient. I know an instance at this moment, of a young lady who was thought to be labouring under spinal disease, and who was kept lying on her back for nine months. It suddenly went away, and then it was suspected that it might be nothing more than hysteria. Such cases, I am sorry to say, are not uncommon. When the patient is young, and there is any debilitating cause, or any irregularity in the catamenia, then you must be especially cautious on this subject, and not believe that inflammation is set up in one or more parts merely because it seems to be so—because you have the symptom of pain. Great evil was done in our profession by that universal system which went to prove that the liver was the cause of all diseases. Every thing painful in the right hypochondrium was referred either to acute or sub-acute disease of that organ, and that, by the way, in a class of the population—viz. young females—the least addicted to those very circumstances which

bring on disease of the liver; such as gross feeding and habits of intemperance. Every thing was put on the liver, and blue pill was the universal remedy. The moment a patient complained of pain in the right side, it was set down that she was bilious, and that it must be purged off with mercury; whereas, in nine cases out of ten, there was only a collection of flatulence, arising from the want of proper exercise and pure air, which are at all times so necessary to the health of the body.

When you find the symptoms very difficult to manage, and you are quite satisfied of the nature of the case, from the time and attention you have bestowed on it, then the proper way is to speak to the patient aside; state that you are satisfied that it is an imposition, but at the same time the feeling must arise from ill health, and you will not say any thing about it if she will not repeat it. This often has a very good effect. Dr. Pemberton has mentioned several cases in which such a practice has been attended with great advantage.

GONORRHOEAL RHEUMATISM.

There are but few cases now remaining in the hospital, and in going round to-day I have scarcely written any prescription.

Unhappily, the case of disorganization of the joints, from gonorrhoeal rheumatism, makes but little progress, though some degree of improvement takes place in the hand. I have been trying counter-irritation in the knees—such as a large blister—and I have subsequently tried tartar emetic ointment, but both produced so much pain that they were obliged to be given up. Fomentations have since been applied, and the patient has been put under the specific use of colchicum, which in some cases does relieve the pain very materially. Still the great length of time during which the patient has laboured under the disease, makes me fear that little will be done. Though he has gained more benefit than could be expected, still his knees are so disorganized that it seems impossible to effect a cure, or at least many years would be required for that purpose. However, I shall not desist from trying all that the art of physic can do.

OVARIAN DROPSY.

The very few cases which were last taken in are all convalescent, and the patients are about to leave us. There is, however, a case of an ovarian tumor on the left side, in Queen's Ward, but the poor woman is unfortunately labouring under derangement of intellect, and therefore I do not expect that much good will be done.

was principally taken in because the pressure of the tumor is such that the woman is obliged to be drawn off twice a-day. It has been put under iodine, which she has been using twice a-day. It may produce a defecation, which it sometimes does, or the tumor may so grow that it will rise above the pelvis, and thereby the pressure will be removed from the bladder. It happens that this is the case. I remember, some years ago, seeing a curious case in private practice. One ovary had fallen down between the uterus and the bladder, and by its weight dragged the uterus as to tilt up the os uteri between the labia; and in this way it prevented proper excretion both of the faeces and of the urine. A sort of retroversion of the uterus took place. I had the patient brought to the hospital, and applied an opiate suppository. By keeping her quiet, and having the urine drawn off, the tumor by degrees became larger, arose out of the place where it was nitched behind the uterus, and the latter organ got right again, so that she was enabled, although labouring with the disease, to go out of the house. The case upstairs is of the same kind. I shall be obliged to try to get rid of the tumor by means that produce abortion; but the growing of the tumor remedies the pressure, and this is the view with which I keep her in the hospital.

correspondent were present at the disturbance,—I mean Messrs. Tweedie, Gaskell, King, &c. Can they be fit judges of that which they did not witness? You evidently have not been informed that the very first breach of order resulted from that "crowding at operations" which you so justly complain of in the present number of your journal. The gentlemen, I believe, did produce their tickets, but they forced themselves into the space around the table, which the porter had been expressly ordered to keep clear. You have not heard, sir, of the impertinent manner in which both Mr. Travers and Mr. Tyrrell were here addressed, and how the latter gentleman was hooted and hissed, because he gave out that it was impossible to operate under the existing state of excitement.

Does it not amount to something more than a misdemeanor, that a multitude of students overpowered a menial, whose most aggravated fault was a strict performance of his duty; and with cries of "throw him over," forced him to the banisters of a staircase two storeys high, and were on the eve of casting him over? Was it nothing that this same multitude turned the current of their fury upon a gentleman whose noble conduct alone saved them from committing an act of violence rendered shocking by its premeditation, and the result of which might have been too frightful to bear a thought? Were the feelings of the patients considered when this outrage actually invaded the wards?

When the proceedings (both private and public) are made known—when the result of the evidence at the Sessions is published, then may you form a candid opinion respecting which was the aggrieved party, and who were the aggressors: then, and not till then, will the public, and the profession in particular, appreciate the motives of the medical authorities at St. Thomas's in prosecuting their charge.

I may add, sir, that so far from implicating the character of the Guy's students generally, considerable regret was, I believe, expressed by the officers of St. Thomas's that they were unable to detect and separate all, or even the worst, offenders. If the Guy's gentlemen have chosen to make the cause their own, surely it is not justice to complain of the course pursued by the insulted to obtain restitution for offended dignity.—I am, sir,

Your obliged correspondent,

A VOICE FROM ST. THOMAS'S.

December 26, 1836.

THE LATE DISTURBANCE AT ST. THOMAS'S HOSPITAL.

to the Editor of the Medical Gazette.

SIR,

A singular error has crept into a letter addressed to you from the St. Thomas's Hospital pupils, by which the whole tenor of the meaning is altered. May I beg you to correct it, by altering the monosyllable "in" in the eighth line, to "by," so that the sentence will stand—"exhibited by the gentlemen then present."*

Very satisfied, sir, that your impartiality will not allow you to be influenced by any statement you have received, or in future receive, from the gentlemen of the Guy's. Let me ask if those gentlemen mentioned in the communication of your

*The error was purely typographical; but the mistake and heading of the letter surely ought to be sufficiently explained.—ED. GAZ.

LETTER FROM THE PUPILS OF
ST. THOMAS'S.*To the Editor of the Medical Gazette.*

SIR,

THE statement which appeared in your GAZETTE of last week, relative to the late proceedings at St. Thomas's Hospital, is verbally incorrect; it being therein said that gross misconduct was exhibited "to strangers;" the original expression being "by strangers."

In justice to the pupils of St. Thomas's Hospital, you are requested to insert in your next GAZETTE the inclosed copy of the letter addressed by the pupils to their teachers; of which it may be observed that it does not assume the form of a protest.

" St. Thomas's Hospital,
Dec. 17, 1836.

"The undersigned apprentices, dressers, and pupils of St. Thomas's Hospital, beg to express to the medical and surgical officers and teachers in general, their indignation at the wanton outrage and misconduct on the part of strangers, which occurred yesterday in the surgical theatre. They respectfully solicit the interference of the officers and lecturers, and desire that such measures may be adopted as shall prevent the like proceedings for the future, and ensure to the undersigned the undisturbed enjoyment of their rights. In furtherance of the above object, the undersigned are willing to forego any and all advantages which may be supposed to belong to their privilege of attending the surgical practice of Guy's Hospital; and, taking into consideration the malevolence evinced on the late occasion, they respectfully submit that all strangers whatsoever should in future be excluded from the right of attending the practice of St. Thomas's Hospital."

Here follow fifty-two signatures.

St. Thomas's Hospital,
Dec. 28, 1836.

MICROSCOPIC DISSECTION
UNDER FLUIDS.

THE late M. Cuvier appears to have been the inventor of the little trough in which microscopic subjects are most conveniently dissected. It is a sort of shallow tray about two inches long, by about an inch and half broad. The mode of preparing it is this:—Take a compound of bees'-wax and Venice turpentine, or Canada balsam, and line the trough with it while warm; then lay in the subject to be dissected, first having dried the parts intended to be fixed

to the compound; and when the whole is cold, the dissection may be commenced, the trough being first filled with water—or very dilute spirit. By using this contrivance, the parts of the subject are more readily separated, and being covered with a fluid, the adventitious portions are easily washed away with a camel's-hair pencil. The knives used for dissecting microscopic subjects are similar to those employed by oculists for operating on cataract.—For some curious information on this and other practical points connected with the use of the microscope, we must refer the reader to Dr. Goring and Mr. Pritchard's new work—the "Micrographia."

NOTICES.

"A Young Practitioner" may charge both for attendance and medicine; but he had better specify the latter, and be moderate. It has been so decided from the Bench.

How are we to know whether the statements of "VERITAS" are true or false? Why not give his name? "HIBERNUS" has not withheld his.

Dr. J. Johnson's letter, in reply to Mr. Copland Hutchison, arrived too late for insertion, as we are this week obliged to go to press earlier than usual.

Communications have been received from Mr. Everitt, Dr. R. Williams, Mr. Eales, Mr. H. L. Smith, Dr. Watson, Scrutator.

LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE XV.

Occasions of medico-legal inquiry respecting the act of Birth—Legal proofs of Concealment of the Birth. SIGNS OF DELIVERY: 1. Recent Parturition—the Signs considered—Woman's Milk. 2. Remote Parturition—the Signs considered. 3. Post-mortem Signs of Parturition, recent and remote—State of the Uterus in recent cases—What may be gathered from the state of the Ovaries—Distinction between genuine and spurious Corpora Lutea. Medico-legal questions—Delivery without assistance—How far the life of the child compromised by it. Parturition without consciousness—Some remarkable cases. Proofs of recent Delivery adduced in the trial Rex v. Angus.

It is a thing of common notoriety, that gross deception has often been practised in reference to parturition, or the act of birth. From an early period it has been an object with legislators to frustrate such attempts; of this the law *De custodiendo partu*, still preserved among our own legal forms, may serve as an instance. In more modern times, the caution observed, particularly in certain foreign courts, under the guise of state and ceremony, to ascertain precisely the birth of a prince, and thus to secure his legitimacy, is well known; nor can we have a better example of the danger of neglecting such caution, than is afforded by the circumstances attending the birth of the Pretender in this country, when, as the story goes, he was smuggled into the royal couch in a warm-

ing-pan—a story which is supposed to have gained more adherents to the house of Hanover, than all the reasonings of Somers, Locke, and the other great advocates of the Revolution*.

But without dwelling on the parturition of princesses, it will be more to our purpose to observe, that on all occasions of alleged bastardy, or disputed legitimacy, proofs of actual delivery are required; and that in all accusations of feigned or concealed parturition, the grounds of such charges, supported by personal inspection, are indispensably necessary.

Women sometimes feign that they have been delivered, when their motive is probably to introduce a supposititious child as an heir to a property; or perhaps their object is to fasten on a paramour a claim to marriage, or pecuniary compensation. Women, again, may conceal the fact of their having been delivered, when they intend, perhaps, to hide the consequences of an adulterous intercourse, or to murder or make away with their offspring.

Legal distinctions.—The crime of concealing the birth is specially denounced in the Lansdowne Act [9 Geo. IV. c. xxxi. § 14], where it is stated, "that if any woman shall be delivered of a child, and shall by secret burying, or otherwise disposing of the dead body, endeavour to conceal the birth, she shall be guilty of a misdemeanor, and be liable to be imprisoned, with or without hard labour, for a term not exceeding two years; and it shall not be necessary to prove whether the child died before, at, or after, its birth."

It is usual, however, to withhold punishment, when it appears in evidence that some preparation has been made for the delivery, as there is thus a presumption raised that the woman expected her infant to live, and intended to bestow some care upon it. Sometimes

* AMOS; MEDICAL GAZETTE, vii. 742.

the proof of such conduct as the preparing clothes for the child, is admissible to negative the charge of intent to conceal.

One or two points are worth observing, with reference to the crime of concealment as just now stated. It is necessary to show that the child is *dead*; otherwise the body of the accusation will be wanting; though, as it is expressly mentioned, it does not require to be proved whether the death occurred *before, at, or after*, the birth. Another circumstance is, that expenses are not allowed in prosecutions for concealment of the birth. This is not only a hardship on the witnesses generally, but has led to a very cruel practice in some instances towards the accused; the woman is indicted for *murder*, though the evidence is wholly insufficient to support such a charge; but the prosecutor by this stratagem contrives to get the costs allowed for a felony prosecution, notwithstanding the jury negative the murder and find only the concealment. It is satisfactory, however, to find that this base proceeding has not escaped the censure of the bench; it has been animadverted on in severe terms, and the costs have been refused*.

Duty of medical referees.—In all such cases the ends of truth and justice are best attained by a reference to medical testimony; and the medical man referred to, can best perform the duty imposed upon him, when thoroughly acquainted with the circumstances which constitute the signs of delivery. Both mother and child must be carefully examined; for it should be perfectly understood, that when the proposed investigation relates to an alleged delivery, one of the first objects to be inquired after is the offspring—either the infant that has been born, or the ovum which has been expelled; without which the case will be defective on the very face of it; the *corpus delicti*, or main fact of the accusation, will be wanting.

Supposing, then, this preliminary point adjusted, our next step is to proceed to the examination of the reputed mother, to ascertain whether there be present about her person the

SIGNS OF DELIVERY.

These signs I shall enumerate in the order usually laid down. They form two distinct classes, it must be observed, according as the inquiry relates to a *recent* or a *remote* delivery. We shall therefore consider them in this order; and first, let us suppose we have to examine a female who is said to have been delivered recently, or

within at least a few days after the alleged event.

1. Signs of Recent Parturition.

Much information may be gathered even from external appearances—I mean from the look and figure of the woman generally. Soon after delivery the countenance is pallid; the eye sunken, and not unfrequently surrounded with a dark or purplish ring; there is an appearance of recent exhaustion; the skin is, however, warm and moist, and the perspiration is remarkable for the peculiar odour which it emits; this is what some of the old accoucheurs called the *gravis odor puerperii*, and is no doubt connected with the lochial discharge, the smell of both having a close resemblance.

The breasts, in general, after delivery, are more full, tense, and tender, or painful, than in other circumstances. The presence of milk, though taken as an isolated sign it is not worth much, for the reasons noticed in a preceding lecture, is yet of considerable importance when noticed in conjunction with other appearances. Of the milk itself, presently.

If, from noticing the countenance and the state of the pectoral system, we proceed to examine the belly, we shall find after a recent delivery the abdomen flaccid, with the integuments in loose folds, and the *lineæ albicantes*—those lines on the abdomen which are seldom obliterated from the part in women who have once borne children—after a recent delivery, remarkably white, intermixed with a bright red, and exhibiting the appearance of shining streaks or cicatrices.

Coming now to the parts of generation, we shall, of course, find them in no one invariable condition; they will exhibit great variations, according to circumstances; but, in general, they bear the marks of having undergone much violence—rubbed, bruised, excoriated, lacerated perhaps, by the passage of the infant. The vulva is red and swollen, the vagina very distensible, admitting the entrance of the hand without much difficulty; the frenulum or fourchette is usually torn, and probably the perineum has suffered. Continuing the examination up to the uterus, we find the *os tincæ* more or less open, permitting the introduction of one or two fingers; the posterior labium of the orifice is described, also, as being the more prominent of the two. The volume of the uterus may, of course, be expected to be considerable; by raising it from within, and feeling externally on the abdomen, the part will generally be felt above the pubes.

If the placenta have not yet come away—if it have been retained either in the

* Sir G. Lewin; Crown Reports, 45.

uterus wholly, or partially in the vagina, the proof of recent delivery is almost as complete as can be desired; in fact, the presence of the child can alone render it more conclusive. All the signs, you will observe, which I noticed previous to the appearance of the placenta, might readily be imputed by an objector to the expulsion of some unorganized mass,—an event which is not unfrequently attended with similar symptoms as regards the countenance, breasts, abdomen, and parts of generation; but the placenta is a master-sign, which can scarcely be gainsaid.

The discharges are the next object to which you should direct your attention. I allude, in the first place, to the lochial discharge, especially if it be simultaneous with a show of milk in the breasts. The order in which these phenomena occur is generally this:—The moment the delivery is accomplished, all the secretions seem suspended for a short time; but presently the lochia make their appearance. The discharge is sanguineous at first, but soon becomes altered, and has assumed a brownish hue by the end of the second day. The milk fever is generally established about this time, but some women never have it. The breasts being now fully distended, a serous fluid (*colostrum*) issues from them ere long, which ultimately is exchanged for true milk. The lochia are frequently suspended during the presence of milk fever, but the healthy condition of the body being restored, the lochia reappear, and continue, in more or less vigour, sometimes for a month or six weeks: they have that peculiarly heavy and characteristic odour to which I just now alluded, and to which Joerg, Meckel, and other German medical jurists, attach a high degree of importance as a sign. The only other thing relating to the lochia worth observing is, that in many instances they alter, from about the fourth or fifth day, to a purulent-looking or milky discharge, which is not readily distinguishable from leucorrhœa, or fluor albus, with which women are often attacked after their accouchment. It should also be added, that it is not uncommon to find, in some women, all appearance of lochial or other discharge at an end as early as the fourth or fifth day.

Milk of the human female.—With respect to the milk, a few particulars noticed by Berzelius and other eminent chemists ought to be attended to.

Immediately after parturition, as soon as the secretion commences, the properties of woman's milk are found different from what they are afterwards. The *colostrum* constitutes the first produce: this is a soapy sort of fluid, of no great consistency,

with some oily flakes on its surface. It is opaque; becomes viscons by exposure to air; grows acid, and putrifies speedily. According to Meygenhofer, the *colostrum* contains more salts than ordinary milk—diminishing in this respect as it approaches the quality of the latter. In the course of three or four days it loses all its peculiar characters.

Of woman's milk generally, it may be observed that it becomes more concentrated when the breast has been sucked for some time. Its specific gravity is from 1020 to 1025. It contains from 11 to 12½ per cent. of solid matters—of which butter constitutes about 5·18 per cent., while cow's milk contains not more than 4·5 per cent.

Such are the chief signs of recent parturition. As to certain other affections which often attend this state,—uterine hæmorrhage, convulsions, suppression or incontinence of urine, prolapsus ani, &c.—being but *extraordinary* signs not usually occurring, they cannot be of much use to us as medical jurists. When they do occur, moreover, it is as independent diseases, wholly unconnected with labour.

But from the facts and phenomena which I have detailed, the following principles may be gathered:—1. That not one of the signs, excepting, perhaps, the actual discovery of the placenta in the uterus or vagina, can be depended on singly, as a probable proof that parturition has recently taken place. 2. But that their combination may enable us to infer the fact to our perfect satisfaction. 3. That it is a much easier task to discover recent delivery when it has occurred in a woman having a first child, the *foetus* also having come to its full time. 4. That we shall be the better enabled to draw our inference as to the true state of the case, when our examination is instituted *soon* after the alleged labour; because most of the signs become less striking, and many of them vanish, in the course of a few days. And, in fine, I may add, as a piece of advice worth attending to, that in making these examinations, we may as well procure as much information as possible relative to previous occurrences—such as whether the female was habitually regular as to her menstrual courses, or rather whether her courses had not been suspended for some months, and whether a sudden diminution of her bulk had not been observed.

I have just said that the examination ought to be made *soon*—without loss of time; but how long a time may elapse, and yet leave us sufficient evidence of what we are in search of, cannot be precisely stated. The generality of jurists and accoucheurs think the period may be ex-

tended to ten days; but a week is probably the utmost that can be safely admitted. Orfila says, that although the medico-legal examiner may have few signs, or proofs, on which to rest his opinion after the lapse of the tenth day, yet, as there may be cases where circumstances are otherwise, he will not by any means assert that a visit at a later period is useless; for in one woman the signs of recent delivery may be as distinct at the fifteenth day as in another at the eighth. However, in general it may be observed, that if women who wish to conceal their having recently been delivered, can so manage matters as to escape an examination till the eighth or tenth day, they may bid defiance to legal functionaries and medical jurists; and the escape of many egregious offenders has been purely owing to such delay.

The same authority gives us a report which may serve to illustrate our present subject. The female who was examined was 25 years of age, and supposed to have been delivered fifteen days previously. "She assured us (says the reporter) that she had never been even pregnant. We proceeded to a personal examination, and found the genital organs not tumefied beyond the natural state of the parts. There was no trace of cicatrix at the perineum. A thick whitish fluid was discharged from the vulva, having a feeble odour resembling that of the lochia, which was further strengthened by examining the linen. The skin of the abdomen was wrinkled, particularly about the umbilicus and groin, with numerous striæ, glistening and whitish. The recti of the abdomen and linea alba were distinctly divided about the navel. Bosom of the ordinary volume; no fluid obtained by pressure from the breasts. By the touch, and the hand applied externally, impossible to detect the presence of the uterus above the pubes. Its orifice semi-open and awry, with labiated structure. On making her walk, we noticed that she betrayed the feeling of slight pains in the articulation of the pelvis. Our conclusion is, 1. That the lady has been *probably* delivered *some* time since; the time may be supposed fifteen or twenty days. 2. To speak positively, we should have seen her ten or twelve days sooner."

2. Signs of Remote Parturition.

We have next to consider what are the signs of a remote delivery,—whether there be any signs by which we may determine that a woman has formerly borne children? The inquiry is by no means merely a curious one, for circumstances may arise where a woman would fain be thought

never to have been a mother, and where her assertion might require to be backed by medical testimony. And on the other hand, women who have never had children may sometimes fancy it their interest to affect the contrary; as the following remarkable occurrence, which had nearly proved serious to the pretending party, will show:—A girl feigned herself pregnant, and deceived her lover into the belief that she was so, with the hope that he would marry her. He, however, remained obdurate, and she carried on her scheme even to the ninth month, when she went so far as to stain her bed and body-linen with some sheep's blood, and confined herself to her apartment for several days, as if she had actually gone through a labour. No marriage, however, took place; and the parties separated. But at the end of two years the lover bethought him that he was a father, and had a desire to see his child: he demanded it in due form, but was of course refused. However, as he would not be denied, he brought the lady before the magistrates, to give an account of what she had done with the child. She then pleaded that she had never had one; but her story was not credited, and she would infallibly have been punished for making away with her offspring, had not the matter been referred to three eminent medical men—MM. Capuron, Maygrier, and Villermay—who were enabled to satisfy themselves that the accused had never been a mother.

But with regard to the signs of remote delivery. If it be difficult to speak positively even in recent cases, how much more so may it not be expected to be when the fact is supposed to have occurred long ago? The points, however, which may serve us in such an investigation are these:—1, The wrinkles of the abdomen which are often left after pregnancy, and which are ineffaceable; 2, Sometimes the separation of the recti muscles in the neighbourhood of the umbilicus, giving a greater breadth to the median line at that part; 3, In certain cases, a cicatrix, which denotes laceration of the fourchette or the perineum, and some irregularity of form about the neck of the uterus. This part is described in such cases as very uneven in shape, and not conical, as it is when pregnancy has not occurred; the orifice of the uterus is also ever after said to remain more or less open, or gaping. The *lineæ albigantes* should not be forgotten, which also are ineffaceable. The abdomen is usually loose and rough, and the breasts flaccid and pendulous. Yet we must recollect that none of these characters warrant us in doing more than presuming that the

woman has once been delivered,—we cannot affirm any thing; while their absence, on the other hand, is conclusive that she has never been a mother.

3. *Post-mortem Signs of Delivery.*

It might perhaps be thought that the proofs were much more attainable and more obvious, when we have an opportunity of examining the internal organs. And so they are,—when we have an opportunity also of seeing the child; and especially when the alleged delivery is recent. Otherwise it may be extremely difficult to come to any satisfactory conclusion.

The post-mortem appearances which may be considered as indicative of a *very recent* delivery are these:—1. The altered shape and augmented volume of the uterus: it will have a flattened flabby aspect, and measure probably from six to eight or perhaps nine inches in length; the os uteri will be more or less open, so that the hand can easily be introduced. 2. The remains of the decidua will be found on the inner surface, loose and flocculent, except where the placenta was attached, and there the parts will appear bare, and exhibit those peculiar valvular openings which have been noticed as the terminations of the veins or sinuses of the uterus.

But these appearances will be greatly modified according to the time that has elapsed after delivery, and also according to the constitution of the woman. In some females, it may be observed, as complete a restoration to the natural condition of the parts will be effected in two or three days, as in others after a week.

The ordinary course of the changes, however, is as follows:—Suppose delivery has taken place at the full time, and that the uterus has contracted well, this organ may be expected to be found in *two or three days* reduced to the dimensions of about six inches long, by three or four broad; its substance will be about an inch thick; and the fallopian tubes and ovaries will appear turgid and vascular, lying by the sides of the womb. After a week, the length of the organ will scarcely exceed five inches; its substance will be reduced, and its colour will appear pale compared with its usual muscular aspect at an earlier date. No very striking or characteristic appearance marks the state of the uterine apparatus later than *ten or twelve days* after delivery; little, therefore, can be expected from an inspection. It is true that the parts probably do not regain their primitive and normal state till after the lapse of about a month: but then the appearances observed in the latter part of this period too much resemble

what might be produced by other causes than delivery, to allow us to form a satisfactory diagnosis.

Corpora lutea.—The state of the ovaries, and the possible detection of a corpus luteum in one of them, may throw much light on the inquiry. I have already noticed the fact of the presence of a corpus luteum affording sufficient indication of a recent conception; and I shall take this opportunity of bringing before you some other points connected with the subject. The following peculiarities (borrowed from Dr. Montgomery's description), mark its presence, so as effectually to distinguish it from other yellow structures sometimes observed in the ovary, and confounded with the body in question.

A genuine corpus luteum is generally oval in shape, and its size is about five-eighths by three-eighths of an inch; its thickness less than its breadth. Its texture is glandular, somewhat like that of the kidney. It is very vascular, its vessels being sometimes visible without any preparation, but almost always (at least until it begins obviously to decline) admitting fine coloured injection thrown in from a branch of the spermatic artery. The course of the little vessels is from the circumference to the centre. As to its colour, it is expressed by the epithet which it bears—*luteum*, a dull yellow or saffron hue; in the recent state, it has a slightly reddish tinge, and has been compared to the buffy coat of the blood. In its centre is observed a little cavity (or “a radiated white cicatrix”), larger or smaller according to the time at which it is examined. Within the first three or four months after conception, the cavity may be about large enough to inclose a grain of wheat; it is bounded by a strong white cyst, the parietes of which approximate and ultimately close up, leaving no appearance at last but that of a cicatrix; and this cicatrix, which is characterized by its being white and radiated, is visible as long as there are any remains of the corpus luteum.

The time of the disappearance of a corpus luteum seems to be variable; but it is supposed to be wholly obliterated by the sixth or seventh month after a delivery at the full period. The corpus luteum of a preceding conception, according to Dr. Montgomery, is never to be found along with that of a more recent, when gestation has arrived at its full time; but in cases of miscarriage, repeated at short intervals, it may.

It is a vulgar error to suppose that the number of children a woman has borne is indicated by the number of corpora lutea found in the ovaries. The mistake seems to have originated with observers who were

not acquainted with the proper appearances of a true corpus luteum, but confounded with them whatever yellow marks were detected in the ovary.

That true corpora lutea are sometimes formed in the virgin ovary, is another error founded in inaccurate observation. It is supposed by those who maintain that they are so formed, that they result from intense sexual desire, or a state resembling the "heat" of animals. But Haller's proposition, I should say, has been fully proved, to be perfectly consistent with truth and fact:—"Corpus luteum in virgineis animalibus nullum est; ex conceptione oritur, neque prius paratum adest." No true corpora lutea are ever found previous to puberty; nor are they found in married women who, though properly formed, are childless, and have never conceived. "If mere imagination," as Dr. Montgomery justly observes, "or highly excited desires without intercourse, are capable of causing such a change in the condition of the ovary, should we not expect to find corpora lutea almost invariably in women who have been living with their husbands, or otherwise enjoying constantly the natural and perfect excitement of the generative system without conception? of the non-occurrence of which consequence we can speak in very decided terms, from numerous opportunities of making examinations under such circumstances."

It may be as well to state in what respects these spurious corpora lutea (called *virgin*) differ from the true ones, or those produced by impregnation. Dr. Montgomery sums up their characters concisely in the following words:—"1. There is no prominence or enlargement of the ovary over them. 2. The external cicatrix is wanting. 3. There are often several of them in both ovaries, especially in patients who have died of tubercular diseases. 4. They are not vascular, and cannot be injected. 5. Their texture is sometimes so infirm, that they seem to consist merely of the remains of a coagulum, and at others appear fibro-cellular, and resembling that of the internal structure of the ovary; but in no instance did we ever see them presenting the soft, rich, and regularly glandular appearance which Hunter meant to express when he described them as 'tender and friable, like glandular flesh.' 6. They have neither the central cavity, nor the radiated cicatrix which results from its closure."

Medico-legal questions.—Let us now proceed to notice a few medico-legal questions connected with delivery, which have been sometimes proposed. We all know that it may, and has in some instances happened,

that delivery has been concealed; mention of it has been suppressed, because, perhaps, the child has been lost through accident or mismanagement. The unfortunate mother dreads the consequences of being thought to have murdered her infant, or she wishes to avoid the exposure attending the fact of having lost her child by mischance. She therefore attempts to keep her delivery a secret; but the child most likely is found, and justice must be satisfied. The question, then, may arise, whether a woman in labour can always save her child if she chooses? In most cases she can or may; for it seldom or never happens that a woman is ignorant of the fact of her pregnancy: she ought, therefore, to have a shrewd suspicion of the probable time of her confinement; and prudence enjoins her to have every thing prepared for the occasion. It tells strongly against a woman in these circumstances that she has prepared no baby linen, nor told any one of her actual state. But again, it must be recollected that accidents may occur. A woman may have a wide pelvis; and in the very act of straining to evacuate her bowels, the child may be expelled. Labour sometimes comes on in the most rapid manner, and a woman may be delivered suddenly while engaged in her ordinary avocations. Even when she is well prepared and situated as comfortably as could be wished, fatal accidents may take place: the accoucheur or the nurse-tender may not be present; the child is expelled; there is a gush of waters; the infant lies on its face in the discharge, and is suffocated. Such things have happened. Dr. Hunter met with a case of the kind, and every accoucheur probably can add some example of the same nature, derived from his own experience.

M. Foderé relates a painfully interesting story of a patient of his—the wife of a goldsmith, who was suddenly taken in labour as she was walking across her room. The child fell from her, and broke the funis. The mother, bathed in blood, caught up the infant and called for help; but no one heard her. She hastily compressed the umbilical cord with her fingers, and was found two hours after in a swoon, with the cord still in her hand. Help even then was luckily not too late: both mother and child were saved.

Delivery without consciousness.—Another inquiry sometimes made is, whether a woman may be delivered without being conscious of it,—or more properly, can parturition take place in a state of insensibility? That such an event should occur during natural sleep (however violent, or impregnation, may be in that state effect-

ed), is, at least in first cases, perhaps little better than a romantic fiction. You will see a beautiful passage in the *Faery Queene* of Spenser, where such an occurrence is related of—

*Faire Crysogone in slombry traunce whilere;
Who in her sleepe (a wondrous thing to say)
Unwares had borne two babes as faire as springing
day.*

And in Wieland's *Oberon*, Amanda is not less fortunate; but in point of fact, or real life, it is only barely possible, and that, perhaps, only where the woman has borne several children before. An instance of this kind is related by Dr. Montgomery, of a lady who was awakened one night by her little daughter, who slept with her: the child became alarmed on finding a third person in the bed,—a baby, born without the least consciousness on the part of the mother.

There are cases on record, and in sufficient number, to oblige us to admit that delivery may take place without the female knowing it—if, for example, she be completely intoxicated, or labouring under the influence of powerful narcotics. Apoplexy, delirium, syncope, or apparent death, are states which may also prevent the mother from being conscious of her labour. Not to go back to the case mentioned by Hippocrates of the woman who, in a state of apparent death from acute fever, was delivered of a child without betraying the least consciousness, there was the extraordinary event that befel the Countess St. Geran, related in the *Causes Célèbres*. She was stupified with an intoxicating beverage, and while in a state of profound trance, was delivered of a child. When she awoke, she found herself bathed in her own blood: her abdomen was reduced in size, and she was in a state of extreme exhaustion. She called for her child; but the object of the conspirators was answered—the child was no longer forthcoming. Sometimes the relaxation of the muscular fibre immediately after death, together with the struggles of the yet living infant, is capable of inducing delivery. One of the most remarkable examples of this kind is given in the *Journal des Savans*. A pregnant woman died, or was dead to all appearance for two hours. M. Rigaudaux examined the body, but could find no pulsation in either heart or arteries: there was foam at the mouth; the belly was greatly swollen; the orifice of the uterus dilated; the membranes were protruding. He determined to turn the child, and take it away by the feet. It seemed dead when brought into the world, but by careful management and attention bestowed on it for three hours and a half, animation was restored.

All this time there was not the least sign of vitality about the mother; but since the limbs did not grow stiff after seven hours from the moment of apparent dissolution, M. Rigaudaux did not altogether abandon hope. He would not allow the body to be removed: he continued his cares, and in two hours and a half more, that is, nine after apparent death, the woman was roused to animation. But the fact of the delivery, which is what we have to notice particularly, is well authenticated.

I find, in the Annual Register, a curious case recorded, which occurred about ten years later than the preceding:—

“On the 12th of August, 1759, the wife of Edw. Knight, of Warwick, was taken in labour about five o'clock in the morning: the midwife who attended her, after giving her all the assistance in her power, believed her to be dead, and then left her. About five in the afternoon, the dead woman was put into a coffin, with a shroud over her. The next morning, the nurse, going into the room where the corpse lay, fancied she saw something move the shroud up and down in the coffin, and ran away, much frightened, to acquaint the people of the house below. They immediately went up stairs to examine what it could be, when, on turning down the shroud, to their great astonishment, they saw a live child grovelling in the sawdust, which had delivered itself from the corpse as it lay in the coffin.”

It may not be improper to add, that a somewhat similar circumstance is said to have happened in the case of the late Mde. Malibran. The attendants were laying out her body after death, when the foetus which she carried came away. Here, however, there could have been no active force exerted by the infant, for it was immature and dead.

In conclusion, I shall take leave to call your attention to a criminal trial, remarkable as having involved two very important points—one of them closely connected with the subject just now under our consideration.

Rex v. Angus.—In this celebrated trial, which took place at Lancaster, in 1808, Mr. Charles Angus was indicted for the murder of Miss Burns, on two special counts, one for poisoning, the other for procuring abortion. I shall here only notice the appearances which were observed in the internal genital system, and which were adduced in evidence against the prisoner on the second count. Miss Burns died suddenly, after forty-eight hours' illness; and the circumstances were so suspicious that the coroner ordered her body to be examined without delay. The following is

that part of the report which it is consistent with our present purpose to extract: — "The uterus was so enlarged as to be capable of containing nearly a quart of fluid. The os uteri and the soft parts were also greatly dilated. Before the uterus was removed from the body, Mr. Hay placed his left hand on the fundus, and introduced his right hand with the greatest care into the organ, until the fingers of the right hand could be felt by those of the left, through the fundus. The uterus being taken out of the body, an incision was made along its whole length, and its cavity laid open. The whole internal surface of the uterus was bloody; and near the fundus there was a well defined circular space of a deeper colour than the rest of the internal surface, and about four inches and a half in diameter. This space was rough and ragged, and a small fragment of what appeared to be the placenta still adhered to it; and the blood-vessels opening upon it were distinctly visible, and as large as a crow-quill, whilst every other part of the internal surface was smooth. The walls of the uterus were about half an inch in thickness: there was no coagulum in it. The os uteri remained in so dilated a state, that the four fingers of a hand, drawn together into the form of a cone, would pass through it without in the slightest degree distending it." It is added, that the vagina had evidently suffered much recent distension, and that the external parts were very bloody.

The inference drawn from these appearances, by the medical examiners, was, that the deceased had very recently given birth to a *child* nearly at the full time; and a positive opinion to that effect was given in evidence at the trial afterwards. But there was not much sound discretion in this: no such strong opinion should have been hazarded in the absence of one most material proof—the *child* said to have been born.

It was objected, on the other hand, that it was very improbable a *fœtus* and placenta had been expelled, because, from the largely dilated state of the uterus, a placenta could not have been detached without excessive hæmorrhage, leaving the womb full of coagulated blood. It was further suggested, that what was called the placenta mark, might rather have been the spot to which a body of hydatids had been attached by a broad footstalk.

The latter objection was very gratuitous; for besides that there were no more hydatids forthcoming in evidence than a *fœtus*, it is pretty plain that no such substance had been expelled; had it been so,

proof of the fact would hardly have been withheld, and the production of a hydatid mass would have gone far to nullify the charge of abortion.

Nor does the other objection seem less feeble. It was evidently founded in ignorance of the true state of the uterus after parturition. From the account already given of the appearances characteristic of a recent delivery, it will be perceived how consistent with the usual condition of the parts were the pathological phenomena noticed in Miss Burns' case. The size of the uterus corresponded with what is usually observed shortly after delivery, and was exactly what might be expected when the birth was somewhat premature. In corroboration of this assertion we have the opinion of Mr. (now Sir Charles) Clarke, who saw the uterus in question. "I have seen," says he, "uteri after the death of patients lately delivered, in whom, however, there was no hæmorrhage, which have been contracted in no greater degree than the uterus which is in the possession of Mr. Hay."

But these were not the only objections to which the medico-legal examiners in this case left themselves open. Without adverting to the evidence respecting the appearances observed in the stomach, which will hereafter more properly be adverted to, it may be observed that the proofs they gathered of the fact of delivery fell far short of what might be expected from practitioners undertaking a medico-legal investigation. It does not appear that they paid the least attention to the state of the *breasts*; a capital omission, as you must be aware from the remarks already made. And what is still more reprehensible, although they all professed to attach great importance to the detection of a *corpus luteum*, as a sign of impregnation, it was not till about six months after they examined the body that they bethought them of opening the ovaries. The trial, in fact, was over, and the prisoner acquitted, when a grand display was made of a *corpus luteum* only then discovered. The uterus and its appendages were brought to London, and exhibited to the profession here; certificates were obtained from Drs. Denman and Haighton, Messrs. Cline, Clarke, Astley Cooper, and Abernethy, expressive of their opinion that the appearances could only be accounted for on the supposition of pregnancy and parturition; and that the presence of the *corpus luteum* put the fact of pregnancy beyond a doubt. But all this looked not well in the eyes of an intelligent public, nor did it contribute much to the reputation of Forensic medicine.

MEATH HOSPITAL AND COUNTY
OF DUBLIN INFIRMARY,*During the Session 1836-7.*

BY PROFESSOR GRAVES.

LECTURE II.

Connexion between disease of the Liver and disease of the Heart—Chronic Hepatitis, from this source, curable in young persons—Enlargement of the Spleen connected with superficial Ulceration of the Legs—Erysipelas and Gangrene, sometimes of a pseudo-inflammatory character—Treatment of this form of disease.

AT my last lecture I endeavoured to point out some remarkable connexions of diseased action observed in certain morbid states of the economy. I shall pursue the subject a little further to-day, as I look upon it as extremely important in a practical point of view. There is another organ whose morbid affections frequently implicate the liver; I allude here to the heart. I have already spoken of certain cachectic states, in which the liver becomes enlarged and hypertrophied as the result of the general derangement of the system. In the present case the hypertrophy and disease of the liver originates in a morbid condition of the heart; this is a very frequent cause of hepatic derangement. You have an example of it at present in the chronic ward, in the case of a poor man labouring under bronchitis of long standing, with disease of the heart, dropsy, and enlargement of the liver. In cases of this description it is a matter of some difficulty to determine in what organ the morbid sequence commences; for where many diseases coexist, it is not easy to ascertain how they are related to each other as cause and effect. I have, however, had several opportunities of observing the progress of the disease from the commencement, and the manner in which the different organs become successively implicated.

Some time ago there occurred a remarkable example of this form of hepatic affection in a relative of mine, aged 14, who, in consequence of exposure to cold, was attacked with rheumatic inflammation of the joints, of a very intense character. Owing to a want of proper care, the disease was allowed to go on unchecked, and metastasis to the pericardium took place. I happened to be out of town at the time, and he had no advice or assistance for nearly twenty-four hours. Pericarditis of a violent character became developed, and

it was only by the most energetic treatment that he escaped with his life. He had pericarditis with effusion, and all the physical signs and symptoms of carditis. After the acute symptoms were removed, the signs of adhesion of the pericardium, hypertrophy, and partial valvular disease, continued; and for a long time the heart's action was invariably accompanied by a loud bruit de soufflet. These affections were followed by dyspnoea and increased action of the heart. But this was not all. He next got inflammation of the testicle, and finally chronic hepatitis with enlargement. The liver grew to a very considerable size; it continued to enlarge for about seven months; and altogether he laboured under a chronic form of hepatitis for more than a year. At last the disease yielded to treatment, and he recovered completely.

This, you will say, was a fortunate termination; but in young persons the powers of nature often act in a very remarkable manner in remedying or removing disease, and cures are sometimes effected in such patients which it would be quite absurd to expect in persons advanced in life. After having laboured under a long train of diseases, and having continued an invalid for nearly five years, this young gentleman at last, owing to his youth and favourable constitution, surmounted all his maladies, and is at present as strong and healthy as any person I am acquainted with. In this instance the chronic hepatitis was the result of the pericarditis, which formed the first link in the chain; and for the space of a year this young gentleman continued to labour under an affection of the liver, the result of disease commencing in the heart. This is a morbid sequence very frequently observed. You have pericarditis, accompanied with inflammation of the lining membrane of the heart, partial disease of the valves, hypertrophy of the muscular substance, and then enlargement and induration of the liver. This is a very common complication, and deserves your most particular attention. When you see a patient whose appearance indicates disease of the heart—who has swelling of the face, dyspnoea, lividity of the lips, and turgescence of the cutaneous vessels—in fact, that peculiar expression of countenance which at once informs the practised observer that the patient is labouring under disease of the heart, you should not neglect to inquire after the condition of the liver, for in such cases it is very frequently in a state of chronic disease. I pointed out this circumstance some time since, in the case of a late surgeon, Mr. M., and directed the attention of the medical gentlemen engaged in the treatment of the case to the liver, in which no one had suspected the

existence of disease. Recollect, therefore, that in many cases of disease of the heart you will also, on examination, find disease of the liver, produced, as far as I can judge, in the majority of instances, by disease of the heart; at least, I think I have never seen any case in which the hepatic affection had the initiative, and seemed to have brought on the organic affection of the heart. In Mr. M.'s case, and several others which I had an opportunity of watching from the commencement, I have no doubt that the disease of the liver was secondary, and that the morbid sequence commenced with the heart. I am quite convinced that disease of the liver may give rise to functional derangement of the heart; for whatever impairs secretion and deranges digestion, will give rise to palpitations, tendency to syncope, and other phenomena of functional disease of the heart; but I have never seen any example of organic disease of the heart as the result of disease of the liver.

It is of some importance to be aware of this complication; for in treating the disease of the heart you must also attend to the hepatic affection, because it has a tendency to aggravate and confirm the cardiac symptoms. This affection, however, is not to be looked upon as acute, or even subacute hepatitis. There is scarcely any pain of the side or tenderness present, and the patient is not always jaundiced; it appears to be scarcely any thing more than congestion, causing hypertrophy and chronic morbid growth. I shall not, however, speak too positively on the subject, as the difference between hypertrophy and inflammation of a low and obscure character cannot be easily determined*.

There is another disease in which derangement of the liver is a common symptom, and I bring it forward chiefly for the purpose of rendering the subject under discussion more complete, as it is an occurrence well known to practitioners, and sufficiently dwelt on in medical books. I allude to that affection of the liver which is observed in cases of intermittent fever. Ague frequently produces a powerful determination to the internal organs, particularly the liver and spleen, and if treated badly, or unsuccessfully, is apt to bring on disease of the liver. The organ becomes congested, hypertrophied, and indurated, and presents a condition somewhat analogous to that which supervenes on disease

of the heart, or results from the cachectic state of constitution produced by mercury or scrofula.

The next form of organic derangement which I shall briefly touch on, is that of the spleen. It is of advantage to place cognate affections beside each other, for the purpose of comparison; by doing so, we frequently derive many instructive and useful analogies. Besides, we have had a remarkable case of enlargement of the spleen in our wards at the same time we had the cases of hepatic disease to which I have alluded. I may observe, that the circumstances under which enlargement of the spleen takes place, differ in many points from those which determine hypertrophy of the liver. We have but few examples of inflammation of the spleen, while the cases in which enlargement and congestion of that organ take place are numerous. From the peculiarities of its anatomical structure, the spleen is very apt to become suddenly enlarged. Like the liver, it may become indurated and hypertrophied from intermittent, or from some general disease affecting the system, and thus lead to a train of secondary phenomena; the most remarkable of which is dropsy. But there is one peculiar symptom attending enlargement of the spleen, which I have frequently pointed out to the attention of the class, as observed at least in two-thirds of the cases, and of which we had an excellent specimen in the patient under treatment in the chronic ward. The history of this symptom is the more curious as showing a remarkable uniformity in the phenomena of a particular disease at very distant periods of time. This is seen by comparing the most recent descriptions of Indian splenitis, as given in an able analysis of Voight's work on the Spleen, published in a late number of the British and Foreign Medical Review, and the description of enlargement and disease of the spleen given by Aretæus. The ancients, it is true, cannot be now considered as authorities to be followed either in pathology or practice; for they were ignorant of many of the most important facts connected with the healthy and diseased states of the human body. In consequence of their inaccurate anatomical notions, they were unable to appreciate or describe many of those details which now enrich the domain of pathological anatomy: their writings, however, are invaluable in many respects, as containing admirable descriptions of diseases which still continue to infest the human body, and as recording certain groups of symptoms which are still associated. A comparison of their descriptions with those of modern times, cannot fail to be extremely curious, and may even prove highly instructive; for if we find that certain inter-

* I am glad to find that this subject has been taken up by so able an observer as Dr. Bright, who, in the third number of Guy's Hospital Reports, p. 605, has made some excellent remarks on the influence of heart disease in producing congestion of the liver. In Dr. Elliotson's Human Physiology, Part I. p. 103, there are some observations which throw much light on the intimate relation existing between the circulation within the chest and the liver.

nal affections have, from the most remote antiquity up the present period, been generally accompanied by peculiar derangements of distant parts, we are authorized in considering this connexion to be something more than accidental, and consequently we may be led to discover relations between organs generally believed to be quite unconnected with each other. Thus, some years, I had three patients in succession under my care, who laboured under chronic enlargement of the spleen, who were all affected with a similar sort of cachexy, and had all the same affection of the skin—namely, superficial ulceration of the legs. This coincidence forcibly arrested my attention, and I was still more struck with the observation, on finding that Aretæus had noticed this very circumstance in his admirable description of splenitis. “If (says he) the spleen does not suppurate, but becomes chronically enlarged, then the patients lose their appetite, and become cachectic, swollen, and of an unnatural colour, while the surface of the body manifests a disposition to ulcerate, particularly on the legs: the ulcers are hollow, round, livid, sanious, and difficult to heal.” This description agrees precisely with the cases to which I have already referred, and it coincides, in a very remarkable manner, with the account lately given by Dr. Voight, of chronic disease of the spleen, as it occurs in India. He observes, that the cachexy connected with the splenalgia Bengalensis frequently manifests itself by a tendency to ulceration; the disposition to which is so great, that leech-bites and blisters occasionally give rise to foul or phagedenic ulcers, which, under certain circumstances, as where the patient has used mercury and is residing in a swampy district, will sometimes run on to a fatal termination. It is also curious, that the predisposing causes of the different varieties of chronic enlargement of the spleen, as given by Voight, are exactly the same as those detailed by Aretæus; and both writers correspond in their statements as to the age and habits of life of persons most liable to this disease, as well as the nature of the locality and the season of the year most favourable to its production. This agreement between authors separated from each other by so many centuries, and who describe the disease as it occurred in distinct regions, and among different races of mankind, is extremely curious, and exhibits a very remarkable example of the identity of the morbid phenomena produced by the same causes.

So far of the pathological states of particular organs which arise in certain conditions of the system, and most generally form a terminating link in the chain

of diseased action. You will perceive that my observations are chiefly limited to a detail of the most important pathological observations made in our wards during the preceding three months. After we have made a brief review of what has occurred during this period, we shall take up the consideration of the cases at present under treatment.

The next disease which came under our notice so often as to deserve a separate notice, was erysipelas. There were some points of interest connected with the history of the erysipelas which prevailed in this hospital during the months of August, September, and October. In the space of somewhat more than two months, we had about twenty cases of this disease; and, indeed, the morbid cause appears to be still lingering in our wards, though less frequently manifesting itself, for we have had only one case within the last ten days. Before, however, I proceed to notice the phenomena of the disease, as observed here, I shall make a few observations connected with the treatment of this affection in general. I am anxious to direct your attention to this point, because the history of this epidemic has furnished some useful lessons, and has shown how much the treatment of any disease will depend on its epidemic character and existing peculiarities. The disease was treated here in every instance, and through all its stages, with wine, quinine, and opium; and, with the exception of a single case, this treatment has proved uniformly successful. Erysipelas, you are aware, is generally looked upon as an inflammatory disease, and its treatment is always more or less antiphlogistic, particularly during the early stage. At this period, it is customary to treat it with general bleeding, leeching, scarifications, purgatives, mercury, and tartar emetic; and I will allow that many cases should be treated in this manner. But the gentlemen who have attended this hospital within the last three months, have witnessed a form of erysipelas which required from the beginning an exactly opposite line of treatment. In the management of the cases which fell under our observation, no one in his senses would think of using general or local depletion, purgatives, or tartar emetic. The moment the disease appeared, we were obliged to attack it with tonics, narcotics, and stimulants. You perceive, then, that in erysipelas there are two very distinct extremes, between which there are many intermediate shades and varieties. It is well to bear this in mind. When you are called to treat a case of erysipelas, you should recollect that it is a disease capable of exhibiting a great variety of forms, amenable to no fixed line of treatment,

and requiring for its management all the sagacity and skill of an accomplished practitioner. I have seen many instances in which this affection appeared in a distinct and well-marked inflammatory form; and I have treated cases with venesection, leeching, purgatives, and tartar emetic, and found these means admirably well fitted to remove the disease. Here, on the contrary, wine, opium, and sulphate of quinine, were the only remedies on which we could rely with any degree of confidence. On the other hand, you will meet with intermediate cases in which these different modes of practice should be employed, either at distinct stages of the complaint and at a considerable interval, or should succeed each other by a rapid transition. Erysipelas, I must again repeat, should not be treated from its name. Many persons have maintained, that when gangrene supervenes on inflammatory affections, and among the rest, on erysipelas, that it is the result of an excessive degree of inflammation, and that it might be successfully combated by judicious depletion. This, however, is by no means generally true; and it is of importance that, in forming proper notions of the pathology and treatment of erysipelas, you should dismiss from your minds all preconceived opinions, and be regulated solely by the impressions derived from correct observation and facts. What I wish to impress upon your minds is, that gangrene may and does occur in cases of erysipelas quite independently of excessive inflammatory action, and requiring a plan of practice quite different from the antiphlogistic. I do not assert that gangrene does not arise in many instances from the violence of erysipelatous inflammation, and that in such cases it is to be met by prompt and decided antiphlogistic treatment, but I think your views of the pathology of this disease will be both imperfect and false, if you look upon the gangrene which frequently supervenes in erysipelas as the result of immoderate inflammatory action. The following case, which is one of extreme interest, will, I think, bear me out in my assertion.

Mrs. B., a lady of middle age, was attacked with feverish symptoms on the 24th of last March. Notwithstanding the diligent employment of antiphlogistic treatment by Mr. Barker, the pyrexia increased; in the course of a few days her throat became sore, and shortly afterwards erysipelas appeared on the face. Her case assumed a very dangerous aspect: she continued seriously ill for some days, and was saved with difficulty. On the 1st of April Mr. Carmichael advised the diligent application of fomentations, with the view of relieving the local symptoms;

and her son, a young man of eighteen, of temperate habits, florid complexion, muscular frame, and who had always enjoyed a vigorous state of health, undertook the duty of applying the fomentations with much zeal and assiduity. Towards evening, he thought, but without reason, that her case was hopeless, and fell into a violent paroxysm of grief, from which he was induced to rouse himself for the purpose of resuming his occupation of applying the fomentations. While thus engaged, he got, to use his own expression, "a whiff of sickening air from the bed clothes," and immediately felt unwell. This was on the 1st of April. On the 2d he was feverish, and complained of headache, for which he got aperient medicine, and was leeches. On the 3d there was no improvement, and he had passed the night without any sleep. On the 4th, Mr. Carmichael considered it necessary to leech the temples again, and to continue the exhibition of antiphlogistic and aperient medicines. He now began to complain of severe pain in the right shoulder, which at first appeared to be of a rheumatic nature. He became more and more restless, and on the 7th of April was reported to have slept none for the three preceding nights. A very perceptible fulness was now observed under the right clavicle, extending down over the pectoral muscle; the parts were tender to the touch, but not red. Mr. Carmichael now examined the hand and arm of the same side with much attention, for the purpose of ascertaining whether any wound or injury had existed, for the symptoms seemed to resemble closely those produced by poisoned wounds. None, however, could be detected. The restlessness now increased to an extraordinary height; during the following night the patient changed from one bed to another at least one hundred times, and the servants were incessantly employed in making and adjusting three beds, from one of which he wandered to another, impelled by an intolerable feeling of anxiety and uneasiness. During this period his bowels were free, his urine copious; and though his fever was considerable, it was by no means proportioned to the nervous excitement; nor was it accompanied by delirium or pain in the head. The swollen parts of the trunk were leeches freely twice, and diligently fomented, and continued to present the same appearance until the 10th, when a red patch appeared near the shoulder, subsequently spreading into a vividly red erysipelatous blush, which occupied the skin covering the pectoral muscle, and right axillary region. I saw him for the first time on the 11th. His pulse was 120, and by no means deficient in

strength; skin hot, but covered with perspiration; he did not complain of headache, but was quite sleepless, and excessively uneasy. His muscular strength was apparently not much reduced, and, indeed, until a few hours before his death, he was able to turn in bed with ease. His tongue was dry in the centre, and furred, but moist at the edges. The erysipelas was now spreading rapidly towards the left side, and down the front of the abdomen. An attempt was made, but in vain, to arrest its progress by the application of nitrate of silver to the skin around its margin, an operation which was performed with great care by Mr. Carmichael. Mercurial ointment was next applied to the inflamed surface, and although the erysipelas continued to spread, we were led to entertain some hopes of our patient, having succeeded, by means of tartar emetic, followed by opium, in procuring for him much, and as he said, refreshing sleep. On the morning of the 13th, however, a black colour of the corium was observed in the situation of one of the bullæ on his left side. This alarmed us; and in a few hours afterwards our suspicions were confirmed by the appearances of dark maculæ in many parts of the erysipelatous surface. These livid patches spread very rapidly, and were in some places accompanied by effusion beneath the cuticle, but in others they appeared to consist in a mere change of colour in the external surface of the erysipelatous corium, without any detachment of the epidermis. The patient took abundant nourishment, and got wine and cordials, but without any favourable effect. The scrotum now became engaged, and speedily assumed a gangrenous appearance. In some places the epidermis separated, and the gangrenous surface of the corium secreted sanies in large quantity, but in many parts no detachment of the cuticle took place. On the 14th, nearly the whole of the right side of the abdomen and the scrotum were superficially gangrenous, and the belly became tympanitic. During this time apparently healthy fæces were discharged in considerable quantity; the skin was covered with perspiration; the urine was copious and natural; and we had here, what is worthy of notice, apparently healthy secretions from the bowels, liver, skin, and kidneys, co-existing with extensive gangrene of the surface. His tongue, however, continued dry and furred; his restlessness unabated; and the sleep previously procured by means of opium now ceased, although that medicine was repeated in the same doses. His pulse also began to sink, but he remained quite sensible and free from delirium until immediately before his death, which took place on the evening of the 15th. During

the latter days of his illness he had sweated copiously, and there was nothing remarkable in the odour of the perspiration. I may also observe, that the pulse likewise furnished but very fallacious indications; for I can assert with truth, that six hours before his death, though soft and compressible, it still possessed a steadiness and a volume by no means calculated to impart a suspicion of his approaching dissolution. His strength was also such as would lead to an erroneous conception of his real danger; for, as I have before observed, he was able to turn in bed shortly before death. This observation is borne out by other cases, in which persons with extensive gangrenous erysipelas, and in imminent danger, have been known to be capable of walking about.

The evidently contagious nature of the erysipelas in this instance, and the youth and previous good health of the patient, render this case sufficiently remarkable. It is likewise worthy of notice, as proved by the circumstances, that the gangrene did not originate in the excessive violence of the cutaneous inflammation, for it did not appear in those portions of the skin which were primarily and most violently affected. On the contrary, we observed that the parts which became gangrenous had been paler and less tense than those which did not assume that condition, and that the portions of the skin which died, were those which had become engaged at the latter stage of the disease. This is of importance; for, combined with other facts, it forms an obvious refutation of the opinion not long since maintained, that gangrene and sphacelus are in all inflammations the result of immoderate inflammatory action, and consequently to be averted by antiphlogistic treatment only. In many instances this opinion, and the treatment founded on it, are, no doubt, judicious; but that there are cases in which the gangrenous tendency supervenes on inflammation, or in other words, is superadded to the inflammatory process, but independent of its intensity, no one will deny who candidly weighs the details of the case which I have just related, and recollects that the conclusions deducible from them have of late received too frequent a confirmation, from the rapidly fatal progress of putrid sore throat—a form of cynanche which has reappeared in Ireland, after having almost disappeared for upwards of twenty years. In both cases the disease appears to be infectious, and in both the gangrene seems to be quite independent of the intensity of the inflammation.

This is a question so important in a practical point of view, that I shall make no apology for detaining you, as I am

anxious to impress upon the minds of my younger auditors, that there are certain forms of disease termed inflammatory, in which the ordinary treatment by depletion is quite inadmissible. I shall at my next lecture enter upon the treatment of fever, and endeavour to communicate such observations as a review of our cases for the last three months has afforded. And here I beg leave to return my thanks to the gentlemen who have furnished the cases, and to express the gratification I have felt in finding that so many of the pupils have recorded their facts in such a clear and satisfactory manner.

THE SECOND SOUND OF THE HEART.

CONTRIBUTION TOWARDS ITS PATHOLOGY.

To the Editor of the Medical Gazette.

SIR,

IN the closing sentence of the interesting *Report of the London Committee of the British Association on the Motions and Sounds of the Heart**, it is observed that the subject "requires further investigation, especially in its relations to pathology."

The second sound of the heart is ascribed in the *Report* to "the sudden closure of the sigmoid valves by the columns of blood that recoil back on them during the diastole, impelled by the elastic contraction of the arteries."†

This explanation of the diastolic sound was first published, I believe, by M. Rouanet, to whom it appears to have been suggested by Dr. Carswell. It is much insisted upon by M. Bouillaud also, in his *Treatise on the Diseases of the Heart*.

The well-devised experiments of the Committee supply strong confirmation of its truth. In the second of the subjoined cases, I offer one out of many *pathological* facts that might be brought forward in support of the same theory. The first case was probably of a like nature; and it was sufficiently remarkable to be worth recording.

CASE I.—James Parker, aged 45, a farm-servant, and formerly a sailor, was admitted into the Middlesex Hospital, under the charge of Dr. Macmichael,

in the year 1830. I transcribe the following account of his symptoms from notes which I took at the time.

"Occasional aching pain in the cardiac region; constant palpitation; shortness of breath, especially upon exertion; slight cough, without expectation; inability to lie on the left side, because that position brings on, or increases the pain, and produces a sensation of weight in the situation of the heart; stooping occasions a feeling of tightness, and as if something is about to give way at the lower part of the sternum; a sudden pain sometimes affects his left arm, beginning at the insertion of the deltoid muscle, and running down to the hand, the little finger tingling meanwhile with that sensation called *pins and needles*. No dropsical effusion.

"A very remarkable sound is audible, accompanying the diastolic movement of the heart, and alternating with the pulse. It is a loud and prolonged noise: judging by its duration, the diastole must occupy more time than the systole. It is heard in all parts of the chest, but most loudly at the upper part of the lower third of the sternum.

"To my ear the sound very closely resembles the smart hum that marks the commencement of the spinning of a large humming-top: others compare it to the sound of a whizgig—of the flight of a beetle or hornet—of the cooing of a dove." Of the singular intensity of this sound, I recorded the following evidence:—"I heard it quite plainly when the unassisted ear was at least a foot from the patient's chest, in a room where several persons were talking. His voice is very resonant through the stethoscope, yet it is not louder than the morbid sound, so heard, of the heart. The patient himself hears the sound at all times; and he states that it has been louder even than it is now, and that his fellow labourers had often heard it in an open road, at the distance of several feet. Every now and then, at irregular intervals, the sound is cut short, or suspended for a moment, and then proceeds again—that is, it is double, like a hiccup interrupting a groan, or like the broken coo of a dove. He is quite aware of this "double beat," and says that whenever it occurs, he feels a sort of crack, and a slight degree of pain, at the back part of his head. A strong jarring thrill, synchronous with the

* MEDICAL GAZETTE, p. 360 of the present vol.
† P. 367.

liastole, can be felt by the hand placed upon the sternum.

"The murmur of respiration is natural, but feeble, except when his breathing is hurried.

"He gives this account of himself. Eleven months ago, being quite well, he was employed in wheeling a heavy barrow of sand, and as he turned it over to empty it, one of the handles struck him on the left side, just below the cartilages of the ribs. The pain produced by the blow was not very severe, but it *continued*, and after about a month it increased in intensity, when he was bled. A fortnight after this the palpitation began. Since that time he has been much in the same condition as at present."

This patient left the hospital neither better nor worse than when he entered it, and I have not seen or heard of him since.

Some time afterwards, a patient came in under my care, with a similar, but much less loud, diastolic sound. He also went away, somewhat relieved.

I am not speaking of the *mere bellows sound* which *not unfrequently* accompanies the second movement of the heart, and which consists of a *rushing*, or *blowing* noise. Yet it may further the object of the present paper, if I state that in every instance of *this* kind, where I have had the opportunity of examining the heart after death, I have found some change which must have rendered the closure of the aorta by the sigmoid valves imperfect. And I had concluded that the same valves were affected in the two cases in which I had heard that different and much louder booming sound, approaching in its tone and quality to the human voice. This conclusion was at length strengthened by the occurrence of a third and *fatal* case.

CASE II.—Thomas Burrin, a butler, aged 36, became my patient in the hospital, on the 27th of last May.

His feet and legs were anasarious, and his belly contained some fluid. He complained of difficult breathing, which prevented him from lying down—of "fluttering" at the heart—and of a slight dry cough.

He had been ailing for nine months, with uneasy sensations in his chest, and palpitation much increased by moderate

exercise. Four days before his admission his legs began to swell. The orthopnœa had existed for a week.

Sixteen years previously, for the only time in his life, he had had "rheumatic fever." His chest was then blistered, on account of pain which he felt there.

Large crepitation could be heard at the lower part of each lung. The first sound of the heart was not unnatural. The second consisted in a long drawn and very loud vocal note, audible to the patient himself, who (unprompted) compared it to the cooing of a pigeon. It was noisier on the right than on the left side of the sternum.

He remained in the hospital till his death, which took place on the 2d of July. His dropsical symptoms had gradually increased, and the dyspnœa, which was permanent, became aggravated in occasional paroxysms of extreme severity. They were more relieved by mustard poultices than by any thing else. The loud cooing sound scarcely varied, and was never absent.

The recollection of the two former cases made the inspection of the body a matter of peculiar interest to myself. Much curiosity respecting it was shewn also by the students and others, it having been conjectured by some that the cause of the sound would be found in a diseased state of the *mitral* valve.

The heart was very large. The pericardium adhered to it at all points, by cellular tissue, which was dry, and evidently not of recent formation; but neither was it dense or tough.

The right side of the heart offered no unusual appearance. The left ventricle was much dilated, and considerably thickened. The mitral valve perfect and healthy. The aorta was narrowed at its commencement by abundant deposition beneath its lining membrane, which was projected into bosses or little tumors, immediately behind the valves. There was a small ulcerated spot on the summit of one of these projecting nodules.

The sigmoid valves of the aorta were curiously altered. They were all irregularly thickened by opaque matter deposited between the layers of membrane of which they are chiefly formed. Two of them were folded, or rather hung back, a little way. Their free margins, to the depth of two or three lines, were quite loose and flapping, so that the

slightest force, even their own weight, was sufficient to incline them to either side, to produce either inversion or retroversion of the loose portion. The edge of the third valve was straight and tight, as usual; but the others could not be pulled tight, so as not to flap. They were all capable of perfect apposition with the sides of the aorta, but the two were evidently not capable of sustaining the backward pressure of the blood in that vessel during the diastole. The stream of regurgitating fluid must have occasioned their loose margins to vibrate; and the vibration doubtless gave rise to the peculiar sound. The physical conditions necessary on acoustic principles, for its production, appear to have been complete.

It can scarcely be questioned that the cardiac disease commenced during the attack of acute rheumatism.

I have the honour to remain, sir,
Your obedient servant,
THOMAS WATSON.

Henrietta-Street, Cavendish-Square,

REVIEW

OF

SOME OF THE PROMINENT NOVELTIES
OF THE NEW EDITION OF

THE LONDON PHARMACOPŒIA;

AND A

Few Specimens of the "great Care, Pains, and Industry," with which the Old Edition has been "Revised, Corrected, & Reformed."

By THOS. EVERITT, Esq.

Lecturer on Chemistry at the Middlesex Hospital
School of Medicine.

In the first place, the measures have all new values; for in the old edition the wine gallon of 231 cubic inches of pure water was taken as a standard; this was divided into eight pints, the pint into sixteen fluid ounces, the ounce into eight drachms, and the drachm into sixty minims. In the present edition the imperial gallon of 70,000 grains of distilled water, at 62°, is assumed as a standard; this is divided into eight pints, but the pint is now divided into *twenty ounces*: the further division as before. Hence—

	Value in Grs. of pure Water, at 62°.	
	Old.	New.
Gallon (231 × 252·45).....	58316	70000
Pint	7289·5	8750
Ounce.....	455·6	437·5
Drachm	56·95	54·7
Minim.....	<u>56·95</u> 60	<u>54·7</u> 60

The present gallon and pint are therefore about one-fifth larger than the old ones; and the present ounce, drachm, and minim, about 1·25th smaller.

I shall not attempt to argue for or against the necessity of this change, nor dilate on the possible results. The difference in the value of the ounce and drachm is so small, that it may in most cases be neglected, and the old measures used for the new.

One of the principal objects of the editors of a Pharmacopœia ought certainly to be, to relieve the medical man from as much as possible of the mental

drudgery of recollecting and calculating proportions: might it not, therefore, have been well, when they felt compelled to alter the value of their measures, in order to make them agree with the imperial gallon, to have thrown overboard all arbitrary divisions of pint, ounce, drachm, &c., and have taken the grain, 10-grain, 100-grain, 1000-grain measures of distilled water at 62°; these still would have been aliquot parts of the imperial gallon. Then, by making all the fluid solutions contain a certain round per centage (a great number might have contained exactly the same)

of the active principle, no calculation on the part of the medical man would be necessary. But by the present regulations we have no unity of design; for some solutions are defined as containing so much for the fluid ounce or drachm—as, for instance, the arsenical solution, half a grain to the drachm; some as containing so much per cent., as the dilute hydrocyanic acid, which is to contain 2 per 100 of real acid; and the same of the other dilute acids, &c. Thus when a medical man has to prescribe hydrocyanic acid, and wishes to come at the quantity of real acid he is exhibiting by measure, he must call to mind—

1st. That the dilute acid contains 2 per 100.

2dly. That the fluid drachm contains 54·7 grains.

Lastly, make the mental calculation, as $100 : 2 :: 54·7 : X$.

Had they defined the fluid drachm to contain one grain of real acid, all this drudgery would be spared.

The next novelty is the “*Notæ breves, ad res chemicas præcipuè spectantes, quibus quidque, sincerum sit, necne quantum fieri potest, deprehendatur.*” These we conceive to be highly valuable; and had they been more extended and precise, and the formulæ in the body of the work entirely omitted, this part would have assumed a form which the present state of things demands.

At a period when every druggist was presumed to *make his ounce and pound* of these chemicals, such formulæ were useful; but now that they are *manufactured by cwt. and tons*, it is quite useless giving processes which few will find either economical or convenient to follow. ●

Here again we observe a want of unity of design; for why have we not a formula for preparing sulphuric acid? “Because,” I suppose they would answer, “any arrangement for making a small quantity, would furnish it at a price ten or twenty-fold dearer than as at present made.” This sort of reasoning applies to all the formulæ in kind, to many even in degree. Now as all these matters (it is, of course, not intended to include mixtures, such as tinctures, plasters, &c., but only definite chemical products) can be so precisely defined

chemically and physically, as to enable any one to distinguish the body named from every other, and to detect the minutest trace of adventitious matter, and as by being manufactured on the large scale they are furnished at a minimum cost, why take the trouble of giving a formula, when perhaps half a dozen others may be equally good, and it will depend entirely on the other objects of the manufacturer which is the most economical. Thus A is a maker of carbonate of soda from salt; he gets hydrochloric acid at the same time. B is a maker of sulphate of magnesia from bittern; he also gets hydrochloric acid at the same time; and this acid, procured from distilling sulphuric acid with muriate of magnesia, is just as good as that obtained from salt by sulphuric acid, provided care be taken to have it pure.

The *third novelty* is the change of names. Although this may be a source of slight annoyance to old practitioners, every teacher of chemistry and pharmacy will hail with joy this alteration, as he was constantly confusing his pupils by a confounding of the scientific chemical names with those used in pharmacy. This, therefore, will scarcely be a change to all those who have been educated within the last ten years, but will be relieving them from the necessity of recollecting the distinction between the two nomenclatures.

We will now give a few instances illustrative of the great care with which this work has been executed.

Amongst the *Notæ breves* we have the strength of the ammoniæ liquor defined 0·960, and of the ammoniæ liquor fortior, 0·882; “liquor hic ad normam liquoris ammoniæ redigi potest, cuique fluid-unciæ adjectis fluid-unciis tribus aquæ destillatæ.” In the body of the work we have no formulæ for making the fortior, but for the liquor ammoniæ—

“R Ammoniæ Hydrochloratis, uncias decem; Calcis, uncias octo; Aquæ, octarios duos. Calcem aquâ resolutam in retortam mitte, dein Ammoniæ Hydrochloratem in frustula contritam et reliquam Aquam adjice. Destillent Liquoris Ammoniæ fluid-unciæ quindecim.”

Now liquor ammoniæ of ·960 contains about 10 per 100 of ammonia; and

liquor ammoniæ of .882 contains about 30 per 100 of ammonia. Hence a fluid ounce at .882 weighs $(437.5 \times .882)$ 386 grains; and $100 : 30 :: 386 : 115.8$ ammonia, 270.2 water. Hence, to reduce this to 10 per 100, or to .960, it will require 774 grains of water, or, in round numbers, 1 f. oz. 6 f. drs.; at any rate, only 2 f. oz. of water to 1 f. oz. of the stronger to reduce it to the weaker, and not THREE, as prescribed.

Touching the formula, perhaps the worst of those in the old edition was that for preparing liquor ammoniæ, and in the present the alterations are merely to suit the new measures. Every 54 grains of hydrochlorate of ammonia contain 17 grains of ammonia. Hence as $54 : 17 :: (10 \text{ oz.} \times 480) 4800 \text{ grs.} : 1511$ ammonia in ten ounces; and 15 fluid ounces at .960 weigh $(15 \times 437.5 \times .96)$ 6300 grains, which, at 10 per cent., gives 630 grains of ammonia obtained, and consequently wasted 881, by the badness of the process.

What manufacturer will follow a process where the loss is more than one-half? I always consider my operation bungled if the loss amounts to five per cent.; and I proceed thus:—Hydrochlorate of ammonia, 10 parts; lime, 8 parts. Put 4 parts of water on the lime, cover it over, and allow it to slake and cool. Put both into a flask having a long neck; pour in 6 parts of water; through a cork which fits the mouth of the flask tightly, put a safety tube, and a gas conducting tube bent twice at right angles; the joint to be secured by lime and white of egg lute. Place the flask in a sand bath; insert the free end of the bent tube to the bottom of a narrow-mouthed bottle, surrounded by cold water, or ice if at hand. Put into the bottle water, according to the strength of the liquor ammoniæ required; for that of .960 about 30 parts; gradually increase the heat of the sand bath, so as to drive over the ammonia and some water. By the time that the 30 parts of water in the receiver bottle have increased to 35 parts, nearly all the ammonia will have passed over.

By operating in this way the liquid has no empyreumatic odour; and I have frequently, on noting the quantity and exact strength of the product, not lost more than two per cent.; which has happened to me in two careful repeti-

tions of this process, made since the new Pharmacopœia came into my hands. If the liquid be required much stronger, it is better to have two receiving bottles arranged, so that what escapes absorption in the first goes on to the second. By having the flask of such capacity that it could contain about three times the quantity operated on, and by its having a long neck kept vertical, all risk of any of the lime salt spirting over is avoided (much of the commercial liquor ammoniæ contains chloride of calcium from this cause), and the product is quite pure. For very delicate chemical purposes an intermediate small receiver is useful, but for pharmaceutical use quite unnecessary.

Hence the ten ounces of hydrochlorate of ammonia could at any rate make 30 fluid ounces at .960, in the room of 15. The great loss is occasioned, *first*, by not putting part of the water into the receiver at the commencement, as sufficient does not pass over when the mixture is first heated to condense the gas; and, *secondly*, by leaving so much water in the retort at the end.

I must confess that this is the worst specimen which a hasty glance has discovered, and that I have experienced great satisfaction at seeing many of the improvements; for having had to lecture for the last six years expressly on the Pharmacopœia at Mr. Grainger's School, it has always been a disagreeable task to comment on many of the old formulæ, which were below all criticism; whereas, in its present form, it will be comparatively a pleasure to go over the same course.

I cannot refrain from stating, that it is a source of some disappointment to me the not being allowed by the College to make a translation, with comments, for my pupils; as four months of last summer, independently of previous investigations, have been closely devoted to experiments on these subjects. I have, however, the consolation to know that the announced work of Mr. Phillips will, as far as my pupils are concerned, render this circumstance unimportant.

There is a misprint in the second formula for dilute hydrocyanic acid, which is not among the errata of the duodecimo edition; and as it is from a suggestion of my own, I wish to point it out here. The proportion of *cyanide of silver*, 9½

grains, and dilute hydrochloric acid, 9 minims, for one ounce of water, ought to be 48.5 grains of the cyanide, and 39.5 grains of the strong hydrochloric, to produce an acid of the defined strength, 2 per 100.

Laboratory, Middlesex Hospital,
Dec. 27, 1836.

ON THE
CAUSES OF THE RESONANCE IN
PERCUSSION.

To the Editor of the Medical Gazette.

SIR,

IN a report of a discussion at the Westminster Medical Society, contained in the *Lancet* of last Saturday, it is stated that my friend, Dr. C. J. B. Williams, contended, in a communication to the meeting "Upon the Theory and Practice of Percussion as a Means of Diagnosis"—"that the sound heard in percussing the chest is not seated in the air contained within the chest, but that it is dependent upon the vibrations of the walls of that cavity, those vibrations being modified by the quantity of air contained within"—"that the chest belongs to that class of musical instruments in which the sound depends on the vibrations of a solid, as in the drum, the string of a harp, &c., as distinguished from instruments in which the notes are the results of the vibrations of the air itself, as instanced in the flute," &c. &c.; the author then proceeding, with his usual ability, to illustrate his position experimentally and otherwise. Those observations of Dr. Williams remind me of the accompanying observations and experiments, which I had intended many weeks since to forward, as I hoped in a more complete state, to the *MEDICAL GAZETTE*, and which you will oblige me by inserting in an early number.

Some portion of them has been made to clear up a difficulty in which I found myself, upon the occasion of a paper on Percussion, read by me some weeks since at the Harveian Society, and containing a view of the causation of pectoral resonance, from which my friend Dr. Williams dissented: I allude to the comparative trials of lung and liver in various media, &c. But the greater part originated in the phenomena of a

case that occurred about six months since, in the Marylebone Infirmary, and respecting the interpretation of which there was some difference of opinion. The former part appears to me difficultly reconcilable with Dr. Williams's theory of percussion, as expressed in the extract above given from the *Lancet*, and as understood by myself from his oral observations at the Harveian Society; and if verified by others, will, as I think, call for some modification of the theoretical views entertained by Dr. Williams on the subject. The latter illustrates a point in semeiology not generally well understood, as I imagine, and yet worth knowing—a point respecting which, at all events, I was myself much in the dark, until I had made the experiments about to be detailed—viz. the ready transmissibility of sounds, such as those occasioned by tapping the chest, and by breathing, through considerable masses of morbid effusion.—I am, sir,

Your obedient servant,

JOHN CLENDINNING, A.M. M.D. &c.

Wimpole-Street,
Jan. 1, 1837.

George Priest, aged 45, servant of a gentleman in Brook-Street, was admitted under Dr. Sims on the evening of June 20, 1836, labouring under symptoms obviously referable to a pleuritic attack. He had been in his ordinary health, which he described as good, until within a month of his admission. He was then affected with pain in his right side, and other pleuritic symptoms. An eminent physician in the neighbourhood prescribed for him, and amongst other things introduced Davis's needle on the side affected, but without obtaining any decisive result. On his admission he complained still of pain in his right side, and had cough and fever, and considerable anasarca; there was little respiratory sound, little resonance on percussion on the side affected, and the motions of the ribs were very slight. On the left side respiration was loud, and resonance and mobility normal; he had the appearance of a person much broken by disease. The pleuritic symptoms were first attended to; afterwards the dropsical symptoms became urgent, and diuretics were ordered. The chest had become round, tense, and distended on the right side, which measured more than an inch more than the left; the

distension was especially observable about the hypochondrium, which became quite tumid. Before this time the edge of the liver had been perceptible far below the level of the edges of the ribs on the right side, and had afterwards become imperceptible to the finger, owing to the tenseness of the hypochondrium. Over the whole of the side affected there remained to the last moment, and even on the dead body, above the summit level of the diaphragm, or from about the nipple upwards, a very easily appreciable degree of pulmonary resonance; far below the normal standard, of course, but still clearly superior to that of the region of the liver, or of any solid organ.

In the Infirmary, likewise, the needle was tried, but, owing to what cause I cannot say, with no better success than out of doors. Nothing escaped from the puncture but a little bloody serum. This might seem to render doubtful the diagnosis; but whatever may have caused the failure of the needle, the real state of the chest could not be questioned. Three or four physicians that saw it agreed without hesitation as to its being a case of hydro-pleurisy; but there appeared still room for doubt as to the precise condition of the lung, as to the extent of the effusion, and the degree of compression and shrinking of the lung. On this point there was some difference, more especially between myself and my friend Dr. Harrison. The remnant of resonance obtainable every where above the level of the nipple, and not affected by change of posture, led me to think that the lung must have escaped total compression, owing, probably, to some attachment to the ribs preventing its complete shrinking back upon the mediastinum; while Dr. Harrison, from experiments on mediate percussion, &c. by M. Piorry, which he had witnessed, and other facts that had fallen under his observation, conceived that the resonance was not less than, or different from, what might be expected in a case of extreme compression and shrinking.

The patient lingered a month, and sank the 19th of July last. Permission was obtained to inspect the body, and the following was the result. I shall notice only the appearances bearing on the subject of the diagnosis.

The body was much wasted, and the

rounded and enlarged right side appeared on that account the more strikingly abnormal in size. The chest gave the same resonance in every part as during life; the whole right thorax was filled with dark serum, amounting to about 14 pints; the lung lay solid and concentrated against the mediastinum, and more forwards than the spine, and was of firm spleen-like consistence; the diaphragm on the side affected was everted, so as to be concave above and convex below; the right half of the liver was thrust down into the umbilical region, and the left half tilted up, so as to encroach upon the regions of the stomach and heart; the stomach was thrust down into the iliac and hypogastric regions; the lungs were on both sides sound, the compressed lung not less so than the normally distended lung.

Such are the memoranda taken on the spot. Now assuming that the serum and compressed lung constituted the whole contents, it is obvious the remnant of pulmonary resonance observed during life and after death, on the diseased side, must be attributed to one or both lungs.

But I could not conceive that the resonance of air could be heard through such a dense medium as the effusion from a distance of several inches; or more properly, I could not believe that a gentle tap, such as used in percussion, would cause audible sound in air at five or six inches distance, and protected from the impulse by a thick layer of dense fluid interposed. I accordingly had recourse to experiment, to satisfy myself of the correctness of Dr. Harrison's view of the matter, and with that intention made repeated trials, with that gentleman's assistance, with sound and unsound lungs, and with the following results, as recorded in my memorandum-book:—

July 29th.—After having removed all the pectoral viscera from the thorax of a female dead of apoplexy, that cavity was filled with water, and a piece of lung was immersed in the water, and percussion practised. The lung was held down under water at various distances from the side, and the tap was always given to a part of the walls of the chest below the level of the surface of the water. When the lung was held within half an inch or an inch of the rib, the resonance was clear and un-

quivocal, though of course not equal to that obtained when the lung was brought into contact with the ribs. At greater distances it was less soft, and much duller, and about four inches from the ribs became obscure.

Now the lung used in that experiment was much charged with blood, and less resonant, probably because more dense than normal. On the 1st of August, therefore, I repeated the experiment, with a lung in all respects normal, but collapsed, of course, and containing but the minimum of air. The chest was filled and percussion used, as before, and various distances tried; and in this case the resonance of the immersed piece of lung could be heard at any distance from the spine to the rib percussed. Indeed my note states that "the piece of lung told, on percussion through the water, from the opposite side of the spine—*i. e.* across one half of the chest and the spine. Every body present was satisfied that the resonance was distinctly audible when the lung was immersed in the water close to; but beyond, the spine."

October 4th.—Lastly, we had an opportunity of trying the experiment with a highly emphysematous lung. In this case, the objection that the resonance in each experiment might be owing to vibrations of the portion of the thoracic parietes projecting above the water, as it was impracticable to fill the chest quite full, was obviated by the use of a screen. The chest was filled as far as it would hold water, and the emphysematous portion of lung was immersed; but instead of modifying the resonance merely by varying the distance between the part struck and the lung, we used a pasteboard screen also, by inserting which, wholly or partially, between them, without change of interval, we produced numerous shades from distinct resonance to dullness, and satisfied ourselves that the emerging portion of the parietes was not the cause of the softer or clearer sound elicited by percussion, when unimpeded by a screen or by distance.

October 14th.—I again repeated the experiment with a screen, with perfectly sound lungs, and with considerable care, and with the same results, for the most part, as before; except that we agreed that the screen did not so completely intercept the impulse of the percussion as to prevent the presence of a piece of

lung being sensible to the ear across half the chest, provided the percussion was pretty strong and the impulse was given in the direction of the lung. I mean vertically to the lung; for any considerable degree of obliquity in the direction of the stroke, we found to diminish, or even to extinguish, resonance in the portion of lung operated on. In this experiment, a split kidney was likewise used as a screen, owing to some doubt respecting the acoustic properties of the pasteboard; and with that fleshy and rather thick screen, the pulmonary resonance was still, though less easily, obtainable.

From the preceding facts, I felt warranted to conclude, that, in cases of hydrothorax, if either lung be nearly sound, there will be no fleshy dullness of resonance in any of the lateral parts of the chest; because, even in cases such as Priest's, in which one lung was consolidated, the opposite lung would yield a certain resonance of a pulmonary character to even moderate percussion on the middle-third of the ribs. Since, however, it might still be doubted whether the interposition of the contents of the cavity of the mediastinum—the trachea, œsophagus, great vessels, bronchial glands, and lower down the pericardium and heart—would not intercept the impulse of a stroke practised on the middle parts of the diseased side in a pleuritic subject, and extinguish resonance of the sounder lung, I made, some days after, the following experiment:—

A chest was filled with water, and a sound piece of lung was immersed, or rather left immersed *in situ*, with the heart, great vessels, trachea, and other contents of the posterior mediastinum entire. Percussion was then practised on the opposite side, and an unequivocal pulmonary resonance was obtained through the water filling the side of the chest percussed and the contents of the posterior mediastinum remaining *in situ*, from the sound portion of lung lodged beyond the spine in the other cavity. This experiment was repeated sufficiently often, and with results sufficiently uniform, to satisfy every observer, when taken in connexion with the preceding ones, that, in the living subject, the destruction of one lung and occupation of the space by water, would not, if the other lung were pretty sound, necessarily prevent the evolution of pulmo-

nary resonance on percussion of the diseased side, notwithstanding the intervention of the contents of the posterior mediastinum, and of a quantity of water sufficient to fill one pleural cavity.

From the preceding case, in connexion with these experiments, then, it appears that, in simple pleurisy, we must not expect to find the pulmonary resonance wholly wanting, even in cases of extreme effusion and compression; and that considerable effusion and compression, and consequently considerable functional lesion of the lung, may co-exist with a degree of resonance of percussion that might readily deceive an experienced observer.

Respiratory sounds.—In the case of Priest, the respiration was audible, distant, and feeble, rather within ten days of his death, when there was already a very copious effusion in his chest. The fact I distinctly remember of a sensation as of a respiratory sound, but at the time (forgetful of certain cursory notices by Andral, Clin. Méd. t. iii.; Piorry, *Procédé Opér.*), I was disposed to think myself mistaken or deceived by some of the numerous sources of fallacy surrounding all observations on living bodies. Since then I made some experiments that show that it really was the bronchial respiration that I heard. On the 25th of November last I procured the lungs of a child seven months old, and immersed them in the chest of an adult, previously filled with water, and then had them inflated through the trachea, and while under water. The lung was first held on the spine under water, and then inflated, and the ear-tube was meanwhile applied to the outside of the chest, and the resonance of the inflation, resembling the normal respiratory murmur, was distinctly heard by my friend Dr. E. Harrison, who assisted me in the experiment, and by other gentlemen, I think, as well as myself. The lungs were then removed to the corner formed by the spine, ribs, and diaphragm, on the floor of the chest, and then inflated, and the ear-tube was applied above the clavicle of the opposite side, or at a distance of more than six inches from the inflated lung, and the respiratory murmur or resonance of artificial respiration was distinctly heard. The lungs were then removed to an open vessel of water, and while immersed were in-

flated; and at the same time the end of the ear-tube was immersed in the water at two or three inches distance from the swelling lung, and then the resonance of inflation was distinctly heard. The lung was then inflated while floating on the water, and the ear-tube was applied to the bottom of the vessel, so as that several inches—as many as three or four—of water were interposed between the ear-tube and the source of sound, and then also the resonance of inflation was distinctly heard.

Experiments similar in essential nature and in result were made with a flexible tube, to imitate the bronchus, through which air was forced by means of an elastic bottle fastened on one end of the tube, and alternately compressed and suffered to expand; but the results were as above, and the experiments with the lungs seem to admit of but one interpretation, viz. that in cases of effusion in the thorax respiratory sounds may be expected to be heard at the usual places, so long as the effusion is not so great as to compress the lung to an extreme degree,—probably so long as any considerable portion of the lung continues permeable by air of the bronchus.

Theory of Percussion.—The preceding experiments relate to the use of the mechanical signs in the diagnosis of dropsical affections of the chest; the following refer entirely to the theory of some of the principal of those signs, especially percussion. I have, in the note accompanying this statement, given extracts from the Lancet report of Dr. Williams's views as to the causation of pectoral resonance, and stated that they differ from my own in that my friend Dr. W. attributes much, or even the principal share, of the sound to vibration of the walls of the chest; whereas I incline to the opinion that those walls are, for all medical purposes, to be considered as but conductors of, and often embarrassing impediments to, sounds elicited by percussion, breathing, speaking, &c. from the viscera they enclose. Of the facts upon which that opinion is founded, the following appear to me sufficient examples. With respect to the sounds of respiration, &c., suffice it to say that I have repeatedly auscultated the lungs during inflation both in and out of the body, i. e. mediately and immediately, and with this only difference, that I heard better immediately than me-

diately: the flexible ear-tube, applied alternately to the chest and to the substance of the swelling lung, gave in the former a feebler, in the latter a louder sound. But to pass from what I am not sure that Dr. W. and I differ about, to what I know we disagree upon, I subjoin experiments, tending to establish, as I conceive, my views as to the share of the walls of the chest in the resonance of percussion.

Taking a piece of sufficiently healthy lung and a piece of liver, as extreme examples, I subjected them to percussion in a variety of circumstances. I had both of them held side by side inside and against the same wall of the thorax, and percussion practised outside the thorax, alternately over one and the other,—and the one gave purely a pulmonary, and the other a fleshy resonance. On repeating the experiment in water, I obtained the like results, the presence of the denser fluid making no material difference. The lung and liver were then removed to a wooden shelf, and percussed mediately with the peximeter and the finger, and immediately with the finger or a scalpel, and with like results in all cases: the lung gave true pulmonary resonance, and the liver that of fleshy parts, hepaticized lung, &c. The same experiment was repeated on a marble table, and with the parts successively suspended in air, and supported on water, without any material difference of result. Now these experiments having been repeated sufficiently often, and being quite simple, admit of but one interpretation, as I conceive, viz. that the wall of the chest is not the source of the soft pulmonary or dull hepatic resonance, which are owing mainly, and, practically speaking, we may say wholly, to the lungs, liver, &c., respectively seated underneath the parietes; and that the walls are but conductors, and often at the same time dampers, of the resonance of the organs beneath them.

“IS TASTE A SPECIAL SENSATION?”

To the Editor of the Medical Gazette.

SIR,
I HAVE perused, in your number for Dec. 17, a letter from Mr. Noble, of Manchester, reflecting upon the paper

lately published by me in the Dublin Journal, upon the relations of the sense of taste, and to which you have paid the compliment of republishing it in your journal. The temper and purport of the letter alluded to have surprised me beyond measure; and being as unconscious of having given to Mr. Noble any just cause for dissatisfaction or complaint, as I am desirous to stand acquitted of the charges which he has endeavoured to father upon me, I solicit your insertion of my reply.

I beg, *in limine*, to remind you that the first paragraph of my paper states, that my design was to communicate the results of a series of investigations into which I had been myself led by the uncertainty which prevailed with regard to the sense; and having thus premised, and in terms tolerably express, that my purpose was to submit my own views and inquiries, I was not prepared for being taken to task for not having introduced those of others further than the course of my own investigations rendered necessary. The letter of Mr. Noble contains three distinct imputations—1, that I have not been candid toward him; 2, that my inferences are, some of them, totally at variance with recognized principles of physiology; and, 3, that the accuracy of my facts is doubtful. He says, “I regret that in assuming to have determined, amongst other things, that taste is a special sensation, Dr. Alcock has not had the candour to refer to what had been previously offered to the profession by myself.” Now, sir, were it even so,—were it true that I had not referred to what had been previously offered to the profession by Mr. Noble, still the want of candour is to be proved. Have I either detracted, or attempted to detract, from the originality, the priority, the validity, the propriety, of Mr. Noble’s experiments and views? Assuredly not. On this his own showing they remain, so far as I am concerned, untouched in all those respects. How, then, can the charge of want of candour apply to me? Would Mr. Noble imply that the doctrine, “that taste is a special sensation,” has originated with him? He disclaims it himself: I have not, then, wronged him there. Would he imply that it was first suggested to me by his papers? Here, were such the case, and I did not avow it, I should certainly have been uncandid; but I can

assure the gentleman that if he thinks so he is mistaken: every tyro in physiology knows that, according to the popular opinion, taste is as real and distinct a sense as any other; and I do not ask too much in claiming credit for the same amount of knowledge. Or would he imply that I have made use of *his* labours without acknowledging the debt? I request that he will show where I have done so, and I will make amends; but if he can not, I expect that he will admit the injustice of his charge. Again, I ask, though I had not referred at all to Mr. Noble or his opinions, where yet was the breach of candour? What was it to me what he or any other man had offered to the profession, if it did not suit my purpose, or if I did not make use of it? And if not, why should I, in the pursuit of my own investigations, refer to it? Am I not at liberty to investigate for myself, and to use my judgment and choose what course I will pursue? And shall I not pursue it unmolested so long as I do not trespass upon that of others? I choose one way, and shall Mr. Noble dictate to me another? Or, cannot one write his own views without violation of candour, unless he bring forward at the same time all the arguments which may have been from time to time advanced upon the subject, whether good, bad, or indifferent? Each man thinks his own the best; and why Mr. Noble should be conceded a compliment above his fellows, I know not. Were I writing a systematic account or history of the question, I should feel myself bound to bring together every thing worthy of preservation, or which I could reach, and I should certainly not omit Mr. Noble's cases and his inferences; but not being in the present case either the chronicler or the trumpeter of any man's opinions, but only seeking after satisfactory knowledge, I did not feel, nor do I acknowledge, any obligation to have occupied my pages, already, perhaps, too much extended, with views with which I was no further concerned than that they tended in the same direction with my own to the establishment of an opinion, to the origin of which neither party had any claim. But, sir, it is not the case that I have "not referred to what Mr. Noble had offered to the profession," for I did refer, when it fell within the limits of my design;

and further, when I did so, I acknowledged it; and I have yet to learn what obligation I was under to go out of my way to do so, and to introduce what was not appropriate, inasmuch as the data from which I reasoned were purely anatomical and physiological, while Mr. Noble's data were pathological,—what was already known, since, according to himself, it has been circulated through several vehicles,—and what, it might be, I did not regard in exactly the same light with its author,—what, at least in my judgment, requires to be confirmed, and put beyond doubt, before, to use Mr. Noble's own phrase, he "can be allowed to have determined the question."

But Mr. Noble "claims priority in having demonstrated, by the best kind of evidence, that taste is a special sensation." Well, be it so: assuredly I have not questioned it; and I call upon him to produce, from my paper, any assertion of priority in the matter at all. When I assert such a claim, it will be time to task me with it; but I am not so puerile as to put forward such pretensions with regard to a doctrine which was received of physiologists before I was born;—I only claim to have investigated the question according to my ability: I found two opinions at hand, and I sought to determine, if I could, which was better founded; and if I have succeeded in throwing any additional light upon the subject, I am entitled to Mr. Noble's thanks for having given confirmation to the view entertained by himself, and not to his censure for want of candour.

Secondly, sir, my inferences are at variance with recognized principles of physiology; and why? Because, says Mr. Noble, it is "a recognized principle in the physiology of the nervous system, that a simple and special function must have but one simple nerve for its manifestation." What doth he mean here? One simple nerve? Doubtless a distinct nerve; else his principle is devoid of force as an objection to my inferences. And further, be it observed that the strict interpretation of his principle is, that the manifestation of a simple and special function *can* have but one simple nerve; else, again, there is no inconsistency in my opinion, that taste has two media of perception. Now, where, among our senses, do we find the con-

firmation of this? There is not one of them which is not provided with more nerves than one; nay, there is not one, with the exception, at the most, of touch, in which the co-operation of two nerves, apparently dissimilar, is not required, at least for its perfect manifestation. Smell is not perfect without the fifth nerve. Injure the fifth nerve, and *amaurosis* is the consequence; and in Mr. Noble's own case of facial paralysis of the fifth nerve, the hearing was imperfect. The inference, therefore, thus far, is not inconsistent. Again: will Mr. Noble please to reconcile with his recognized principle, the fact that, according to the highest anatomical authorities, the auditory nerve is in many fish only a branch of the fifth? Will he reconcile with it his own conclusion—perhaps, to avoid imputation of want of candour, I had better say, though he appears to dislike the word, the suggestion—that the chorda tympani and the other branches of Meckel's ganglion are the nerves of taste? They, too, are branches of the fifth nerve; and their special character he has not proved. Or, again, his own reasoning with regard to the glosso-pharyngeal nerve. According to him, “the simplicity of origin” of that nerve “is not questioned;” and “a nerve whose origin is simple, can subserve one function only.” Yet, if he take the trouble to examine the distribution of the nerve in question, he will find abundant reason to doubt its singleness of function. But Sir Charles Bell and other leading authorities decide in favour of Mr. Noble. Be it so; but are there none of a different opinion entitled to consideration? I would suggest to Mr. Noble, even for curiosity sake, to consult the writings of Magendie, and he will find that that physiologist almost goes the length of maintaining that the fifth nerve subserves the three senses of smell, sight, and hearing; also those of Dumeril and Serres, from which he will learn that those authorities are of opinion that, though the dolphin has not got an olfactory nerve, yet that it enjoys the sense of smell through the fifth; and that several animals which are devoid of optic nerves, can yet see by means of the fifth. And further, that Cuvier, who is entitled to some respect in those matters, held “that the difference of the functions of the nerves depends rather upon the different organization of the

parts to which they are distributed, than upon their proper essence.” Therefore, if the battle is to be fought with authorities, it would seem that they are to be had on both sides, and that Dr. Alcock's inferences might contradict all Mr. Noble's leading authorities, and yet find others to countenance and support them; nay, that they might find authorities in nature—“the best kind of evidence”—to justify them.

Lastly, sir, facts are stubborn things; “but the accuracy of the facts themselves must first be established; and that Dr. Alcock's paper furnishes the proofs of such accuracy, most, I conceive, will be inclined to disallow.” This charge I know not how to treat, because it is equivocal and offensive, leaving an imputation upon my veracity, to be understood according to the reader's pleasure; and further, because he adds, “I do not, however, propose to examine *seriatim* and in detail the various proceedings which were adopted in this gentleman's experiments.” And if not, sir, how can their accuracy be decided? or who, without such examination, can pronounce judgment upon them? Mr. Noble, it appears, has ventured to do so. But why not examine, and rigorously too? It is what I desire, and what I have endeavoured to do myself: I do not pretend to infallibility, and I promise, when convicted of error, to acknowledge it. This question I leave to Mr. Noble to answer: I cannot suppose that he would pronounce a judgment which he was unable to maintain.

One obligation, however, I owe to Mr. Noble, and I hasten to acknowledge it. His letter has led me to discover a misconception into which I have fallen with regard to Mayo's repetition of the experiments of Panizza. In my perusal of his paper upon the subject, in a former number of the *GAZETTE*, I understood him to say that he had divided the glosso-pharyngeal nerve on one side, and the lingual branch of the fifth on the other; whereas, on reference, I find that it is “lingual branch of the same nerve on the other.” The experiment, as I understood it, appeared to me inconclusive, and I have said so; but I take thus the earliest occasion to correct my mistake, which I can explain only by the use of the terms “lingual branch,” inasmuch as the lingual portion of the nerve is not in the

dog a single branch, but a leash of branches, among which it is not possible to distinguish, in the living animal, those especially intended for the tongue from the rest, and by the habit, which I have for some time adopted, of calling the "gustatory" nerve (so called) simply "the lingual branch of the fifth."—I remain, sir,

Your obedient servant,

B. ALCOCK.

Dublin, Dec. 26, 1836.

DR. R. WILLIAMS ON FEVER,
AND THE "ELEMENTS OF MEDICINE."

To the Editor of the Medical Gazette.

SIR,

I FEEL much obliged to the reviewer of the *Elements of Medicine* for pointing out a typographical error which had escaped me, and in which the word *saved* has been substituted for *lost*. The passage should have been thus:—"The cholera was preceded and accompanied, and followed by, a fever of great severity, and the treatment by enemata in those years has been by no means so successful, one being lost out of four or five."

As the value of the work depends altogether on the soundness of the principles on which it is based, it may not be unimportant for me to state, that we have had this season, in St. Thomas's Hospital, the strongest confirmations of the contagious nature of typhus fever. Early in the autumn, two cases were admitted into Edward's ward, ill of a severe fever, and, in a short time afterwards, four other patients in the same ward were seized with the disease, while the sister and nurse also caught it. The sister suffered very severely, so that many thought it impossible she could recover, and her symptoms were remarkable, for her pulse, which beat the other day at 84, was counted for several days during the fever as low as 32 and 33 in a minute. She* recovered by the use of the enemata, a few leeches to the abdomen, and mustard poultices; but the nurse, an aged woman, died.

The pathological phenomena in two

cases that have fallen within the last few weeks, have been strikingly different; for in the nurse just mentioned there was no trace of disease in the alimentary canal, neither was there any injection of the membranes of the brain; and the only morbid appearance found was effusion of serum into the arachnoid cavity; while, in a boy that died in King's ward, the follicles of the colon were generally enlarged and strongly marked, the appearances of the head being also trifling. I should have anticipated the best results from the use of enemata in this latter case, but the patient obstinately opposed their use; and it is singular, he was more affected with delirium than the nurse.

The liberal adversary with whom I have to contend, and who evidently has left the university much later than myself, will, I am sure, not be offended when I state I do not understand his logic. This art has never been made plain to ordinary understandings, and I am quite sure, had Mrs. Glass affirmed "there is but one famous Christmas-pudding known in this country, and that is made of plums," that no power could have persuaded her she had asserted, "therefore, all our puddings are made of plums." The disjunction of the substantive from its adjective, is, I apprehend, unprecedented in reasoning. I certainly am astonished, when every medical authority admits nine-tenths, at least, of the patients labouring under typhus, pass into a brown-tongue stage of greater or less intensity, any doubt can exist that it is a law of the disease, the typhoid poison does not wear itself out, or else the patient does not become insensible to the action of the poison until it has produced the greatest state of depression consistent with human existence; for surely every law is deduced from the great majority of facts, and though rendered less universal, is not superseded by the exceptions. I am also surprised that the "*Elements of Medicine*" should have been considered as an improper title, and as synonymous with what is usually termed an elementary work. Cullen adopted "*First Lines*" as the title of his book, although it was the profoundest treatise on medicine then extant. But this great man compared, in his own mind, the little that was known of our vast science, with what remained to be accomplished, and clearly saw his sketch was only des-

* Soda-water, the best of saline medicines, was allowed *ad libitum*, but she could not, after a bottle or two had been taken, be persuaded to persevere, and its exhibition was abandoned.

tinued to lead the way to greater discoveries; and the proportions of a child are not more dissimilar to those of the man than is the system of Cullen to the present state of medical science. I believe there is no error, therefore, in the title I have adopted. I reasoned as Cullen had reasoned before me, and had certainly no intention of misleading the public. It is not, however, my intention to prove the truth of the line of Pope—

“ Ten censure wrong, for one who writes
amiss ;”

but to thank him for his courtesy in attributing the error he has pointed out to its right cause; to assure him the leaf that contained it is already cancelled in the unsold copies; and to add that your kind insertion of this admission of the mistake in your valuable journal, may, perhaps, enable some of those who possess the work to correct it.

I remain, sir,
Your obedient servant,
ROBERT WILLIAMS.

Russell Square, Dec. 29, 1836.

CASES IN OPERATIVE SURGERY; WITH REMARKS.

To the Editor of the Medical Gazette.

SIR,

If you consider the following cases deserving of publication in your journal, they are at your service.

Believe me, sir,
Your obedient servant,
F. C. SKEY,
Assistant-Surgeon to St. Bartholomew's Hospital, &c.

Charterhouse-Square,
Jan. 8, 1837.

Removal of a portion of the Lower Jaw.

Mrs. M., aged 56, residing at Wimbledon, accompanied by Mr. Tapley, her medical attendant, consulted me in the latter end of September last, relative to a diseased condition of the lower jaw. On examination, I found the walls of the bone on the right side considerably separated by a morbid growth of a somewhat remarkable character, occupying the situation of the molar

and bicuspid teeth. The extreme breadth to which those walls were separated was about an inch, which rendered her cheek prominent. Both the inner and outer gum were more than usually vascular and tumid, and pressure on either occasioned pain. The teeth had been either removed or had come away spontaneously, at a date of many years antecedent to the first appearance of the disease. The alveoli were occupied by the diseased growth, which, apparently arising from their base, extended upwards to the level of the swollen gum, in the form of thread-like processes, terminating either in rounded or acuminate extremities; the whole possessing a sort of verrucous or cauliflower character. The disease extended beyond the original situation of the last molar tooth posteriorly, and reached, in the direction of the symphysis, the first bicuspid.

No other structure appeared to be involved, and the basis of the bone, as likewise the cervical glands, were to all appearance healthy.

The disease had existed about six months, and was attended by considerable darting pain, recurring at irregular intervals, which increased to a degree sufficient to occasion sleepless nights and generally impaired health. The slightest violence produced bleeding from the tumor, not always readily controllable; and this symptom was likewise on the increase at the date of her visit to me.

I had no doubt, on inquiry and examination, of the necessity of its removal; and being unwilling to undertake a large operation without the concurrence of some professional person, I requested the opinion on the case of my friend Mr. Kiernan, who coincided with me in the necessity of an early operation, although, like myself, he was uncertain of the precise nature of the disease.

I performed the operation on the 29th of September last. I had previously seen several similar operations for the removal of the half of the lower jaw, but in each an incision was made, which appeared to me in some degree objectionable, viz. that of the cheek, commencing at the angle of the mouth, and extending outwards to the masseter muscle. This, for reasons I shall hereafter state, appeared to me unnecessary

in this case. Having placed the patient in a convenient position, I made an incision from the symphysis to the angle of the jaw down to the bone, and divided the facial artery, which I immediately tied. Introducing the forefinger of my left hand into the mouth, I passed the knife from the wound upwards between the cheek and the gum, which were separated from each other to the extent of the external wound. Without waiting to tie many smaller vessels that were bleeding profusely, I pressed the tongue to the opposite side, and divided the mucous membrane which forms the floor of the mouth and the attachment of the mylo-hyoideus muscle to the bone, with a curved knife, the point of which was supported on my finger below, the inner surface of the bone being the guide for the incision. I had then the whole bone insulated. With a large pair of Liston's forceps, I divided the jaw near the symphysis, which split through without difficulty, and I again introduced them into the mouth, passing them backwards to the angle of the bone, which was in like manner easily divided, and I had the whole diseased growth removed. I then observed the sublingual gland, which was exposed, and as it appeared somewhat indurated, I removed it with one or two strokes of the knife. Many vessels were divided, and the hæmorrhage was considerable. I tied some arteries from the internal pterygoid and masseter muscles, and a branch of the submental. Wet lint was applied to the wound, and the patient was carried to bed.

The operation occupied 11 minutes. In an hour afterwards I removed the lint, and as all tendency to bleed had apparently ceased, I united the sides of the wound by means of two sutures, and requested that wet lint might be reapplied over them.

In six hours after the operation, in consequence of an attempt to speak, such considerable hæmorrhage recurred as to induce Mr. Tapley to divide the sutures and expose the wound. The bleeding ceased, and on the following day our patient was free from pain, and suffering merely from symptoms attendant on loss of blood. There arose no other drawback to her recovery, and she was convalescent in a month after the operation.

A section of the bone exhibited the

full extent of the disease, which had apparently commenced in the alveoli, and extended in the direction upwards by the formation of the thread-like processes I have above alluded to. It had likewise extended backwards towards the angle of the jaw, in the form of a whitish, somewhat schirrous-looking growth, which having imbedded itself in the substance of the bone, was gradually producing absorption of its more cancellated texture in this direction.

In reference to its malignant character or otherwise, great uncertainty existed; and it was exhibited to many men eminent in the profession.

Hitherto there has been no recurrence of the disease, and her health is perfectly reinstated.

I conceive the operation performed in this case to possess advantages over those which I had previously witnessed, both immediate and prospective. The operation is more simple. There can be no error as regards the first incision, either as to direction or depth. There is no danger of wounding the parotid duct, nor of making a second division of the facial artery, which is almost inevitable to the other operation. The bone is more immediately under the incision, and consequently more readily exposed, whereas, in the operation commencing by a transverse incision through the cheek, from the angle of the mouth, the diseased bone always lies more or less concealed, unless the incision indeed be very extensive.

Should secondary hæmorrhage occur, as in the above case, it is always preferable to have a direct rather than an oblique wound in the bottom; if not, the blood may accumulate.

If the external wound be immediately over the bleeding vessels, the trickling from the wound would admonish the attendants of the impending evil.

I am aware that much may depend on the extent of the disease, which may involve not only the base of the bone as far as the angle, but even the ramus as high as the condyle or coracoid process; and again, this extent may not be determinable till the operation is advanced. But notwithstanding the possibility of these difficulties, I should prefer the division along the basis, because, under all circumstances, a considerable part of the ramus, probably its inferior half, might be commanded from the lower

wound; and should the disease be found to extend beyond the part exposed, I conceive it would be perfectly unobjectionable to make a division *across* the masseter, which would avoid the otherwise necessary injury to the portio dura nerve, effected by a vertical one.

The prospective advantage is that which arises from avoiding the deformity produced by the division of the face. In the case above detailed, the deformity is so slight as to be almost imperceptible. There remains a slight hollowness of the cheek on that side, but nothing to indicate that so severe an operation had been performed.

Taliacotian or Rhinoplastic Operation.

W. Detheridge, aged 52, called on me about the latter end of August last, with a letter from a medical friend, containing a request that I would examine his face, with a view to the performance of the Taliacotian operation.

The man stated that he had been at various times under the advice of experienced and eminent surgeons, but that all had declined his most urgent request that some attempt might be made to amend his unhappy condition of features attendant on the partial loss of his nose.

There was an earnestness in the man's appeal, almost imploring my assistance, accompanied by the assurance that he could not live to be the object of scorn and derision of all his acquaintance, that induced me to believe that there were some grounds for the suspicion that he was the subject of insanity. On investigating the circumstances attending the case, I ascertained that he had been endeavouring for twenty years to obtain the consent of some surgeon to undertake the operation, but all had prudently declined. He seemed to consider me in the light of a last hope, and employed all his eloquence, of which he possessed a more than ordinary share, to induce me to do that which the *élite* of the profession had declined, and in this he certainly succeeded, but not till I had convinced myself that his eccentricities were referable to too obvious causes to render my refusal inevitable on that score.

I considered the man to possess a large share of personal vanity, and to be exceedingly and morbidly sensitive to any

defect which involved his personal appearance.

From the days of his boyhood he had suffered considerable annoyance from the discoloration of his nose on exposure to cold. He complained that he could never keep it at the right tint of colour—warmth reddened, and cold blanched it. With a view to meet the effects occasioned by the variation of temperature, he carried in his waistcoat pocket a quantity of chalk, with which he was accustomed to rub his nose as occasion required.

After a time, however, this expedient failed him, and he made a serious request to a medical gentleman to cut off his nose, and make him another of better materials. On the refusal of this gentleman to accede to his wish, he returned home, and with his own hand cut off the extremity of the offending organ, by an incision which commenced about one-eighth of an inch below the nasal bones, and passed down obliquely to the middle of the lateral cartilages. He then renewed his application to the surgeon, in the hope that all objections were removed.

On the assurance of the man's mental sanity, by two medical gentlemen of the highest professional respectability, who had known him for many years, and influenced by his own urgent entreaty, repeated in defiance of my assurances that the operation would be both a tedious and a painful one, and possibly at last unsuccessful, I consented to undertake it.

The operation was commenced by paring off the skin covering the remaining part of the nose, leaving well defined margins all around. This the man bore with the most stoical indifference, as indeed he did every stage of the operation. He felt himself the hero of the day, with which something of the ridiculous was blended, as though he were paying the penalty due to his previous folly. The bleeding continued from the exposed surface for nearly $\frac{3}{4}$ of an hour, during which time the wound was sponged with cold water, and at length covered with lint, and the blood allowed to coagulate. When the bleeding had ceased, having previously marked with a pen and ink the exact form and dimensions of the skin to be removed from the right brow, and which were in all dimensions more than suffi-

ciently large to cover the surface exposed, I divided around, having a bridle directed towards the root of the nose, of about half an inch in breadth. From this flap, thus almost insulated, sundry arteries from the frontal bled considerably, and one among the largest poured out its blood, *per saltum*, from the point or tongue into which the flap was prolonged, and which was destined for the septum.

Before the flap could be finally adjusted on the nose, more than half an hour was occupied in arresting the bleeding from it, and I was compelled, though somewhat unwillingly, to place a ligature on a vessel that bled most pertinaciously from the side of the bridle. During this process the temperature of the flap became much reduced, and the surface of the nose was again covered with coagula. These being carefully removed, the flap was turned at the bridle and laid down over the nose, which it was found to fit accurately.

Fine sutures were introduced down each side, at a distance from each other of about one-third of an inch; and, finally, I fixed up the tongue of the flap by two sutures passed across it, through its bleeding surface, and carried through the lower edge of the old septum: these two last, therefore, did not penetrate the skin.

The time occupied by the operation itself did not exceed twenty minutes, although the man was under the hands of his attendants for fully as long a period as I had anticipated. He had a slight attack of erysipelas in the following week, but notwithstanding this the integuments united perfectly. In one or two places, a groove was left between the old and new surfaces. These defects I have subsequently amended by removal, at the same time with a view of reducing the necessary bulk of the organ within moderate dimensions, and in this I think I have succeeded.

For six weeks after the operation, all the external sensations of the new organ were referred to the forehead, and to the exact spot which corresponded to the part touched. These, however, ceased the moment I made a division near the root of the nose, for the purpose above alluded to, and they have not returned. The man is proud of his new acquisition, and I do not regret being the

agent of his possessing it. As the beauty of the nasal organ must ever continue a matter of taste among the community at large, I cannot speak of its relative merit in this instance, but a man has probably the best right to appreciate his own; and he, being a vain man, is pleased, so I am satisfied; and perhaps I may venture to add, that general report speaks favourably of it.

The great difficulty, I imagine, in cases of this kind, arises from the dissimilar character of the integuments employed, to those for which they are substituted. It is impossible, by a single operation (at least the attempt would in all probability fail), to form a nose of natural dimensions from the forehead, because the integuments of the nose and face generally are thin, whereas those of the forehead are of more than ordinary thickness. Indeed, under any circumstances, I presume that considerable thickness would be required to insure circulation of the blood.

In the above case I have succeeded to some extent in reducing the portly character it at first possessed, by means of a pair of forceps constructed for the purpose of obtaining lateral pressure, the two blades of which are curved to fit the nose. It appears to me impossible to complete an operation for making an artificial nose at "one sitting;" the margins must be more or less abrupt, and the bulk large. In the above case I have reduced this by two or three subsequent operations, in each of which I have removed considerable portions of the new integument; and we are thus enabled to make a cleaner adjustment of the two edges, between which the former cicatrix should be included. Considering the motives for the operation, I do not imagine that any obstacle to these pruning incisions would arise on the part of the patient.

As so much depends on the exact apposition of the opposing surfaces, it appears to me that in this, as in all operations on the face, too much care cannot be bestowed in accomplishing this object. I am myself in the habit of applying, in addition to one or two large, several exceedingly small sutures, to the purpose of attaining the desired end; these latter, however, I generally remove within about 30 hours after the operation.

ON THE
HEIGHT OF THE DIAPHRAGM.

To the Editor of the Medical Gazette.

SIR,

ONE of the most singular discoveries, to which I have been led in connexion with certain researches into physical signs, is the utter *practical* ignorance generally prevailing among the medical men I have conversed with, as to the height at which the diaphragm is situated in different individuals.

Some there are who can, with a tolerable approach to accuracy, state from books or lectures its average height, but who start with surprise, if not with fear, when its real height in their own case is pointed out to them. Others, with scornful incredulity, draw from their own imperfect knowledge of this point arguments to invalidate the accuracy of signs which I have, in the presence of competent judges, put to the test on the living or the dead, or in both these states.

This ignorance is the more remarkable, as it is not confined to mere tyros in medicine, but extends to men who have been long and successfully engaged in the study of morbid anatomy.

It is not my present business curiously to inquire into the means which the great authorities on percussion and auscultation must be supposed to be in possession of, in order to give them a facility and precision of diagnosis which seem to be scarcely compatible with a want of knowledge as to the height and different degrees of obliquity of the diaphragm in the cases that come under their notice.—I remain, sir,

Your obedient servant,

EDWIN HARRISON.

Dec. 31, 1836.

ANALYSES AND NOTICES OF BOOKS.

“L'Auteur se tue à allonger ce que le lecteur se tue à abréger.”—D'ALEMBERT.

Pharmacopœia Collegii Regalis Medicorum Londinensis. 1836. Printed by Order of the College.

In our number of the 24th ult., we noticed the appearance of the New Lon-

don Pharmacopœia, and we propose now to offer a few remarks on certain portions of it. We have already stated that many new and valuable remedies have been introduced, and, so far, much service has been rendered to medical science; but as we are “nothing if not critical,” we shall proceed to point out several objections which occur to us: and first we must say, that, considering the length of time the work has been in preparation, a list of “*Errata* and *Corrigenda*” ought not to have been necessary. Yet both in the octavo and small edition we find one: a convincing proof of inexcusable carelessness, more particularly as the principal errors are not attributable to the printer. For the credit of the College, it had been wiser, in our opinion, to have cancelled the leaves requiring correction, and which might have been effected at a very trifling cost.

In the Preface, allusion is made to the attempted production of a British Pharmacopœia—that is, a joint Pharmacopœia for England, Scotland, and Ireland. The failure of this laudable attempt is ascribed to the great distance of the parties from each other; which, however, we cannot admit to be a sufficient reason, and we cannot but suspect that other difficulties, of an entirely different nature, have also operated in preventing this desirable consummation.

Articles struck out.—In the “*Materia Medica*,” we observe that a few articles contained in the former edition are now omitted—namely, *Fucus vesiculosus*, *Helleborus foetidus*, *Linum catharticum*, and *Rubia tinctorum*. Many other substances, in our opinion, might also have been left out; as *Oxalis Acetosella*, *Rumex Acetosa*, *Acorus Calamus*, *Malva sylvestris*, *Cardamine pratensis*, *Cydonia vulgaris*, *Laurus nobilis*, *Allium porrum*, *Ostrea edulis* (*Testæ*), *Tussilago farfara*, &c.

Articles introduced.—Under the head of “*Materia Medica*,” we observe the following new remedies:—*Barytæ carbonas*, *Brominium*, *Chimaphila corymbosa*, *Creasoton* (described as “*Oxyhydro-carburetum ex oleo pyroxylico paratum*”), *Diosma crenata*, *Ergota* (*Acinula clavus*), *Ferri percyanidum* (commonly termed Prussian blue), *Iodinium*, *Lobelia inflata*, *Strychnos Nuxvomica*, *Cissampelos Pareira*, *Phosphorus*, *Potassæ chloras*, *Potassii ferrocyanidum* (the prussiate of potash of the

shops), and *Helonias officinalis* (Sabadilla).

Among the "Præparata et Composita," the following are the principal new articles:—Acetum Cantharidis, Acidum hydrocyanicum dilutum, Acidum phosphoricum dilutum, Aconitina, Morphia, Morphie acetas, Morphie hydrochloras, Quinæ disulphas, Strychnia, Veratria, Carbo animalis purificata, Argenti cyanidum, Barii chloridum, Calx chlorinata, Hydrargyri bicyanidum, Hydrargyri iodidum et biniodidum, Plumbi chloridum, Plumbi iodidum, Plumbi oxydum hydratum, Liqueur potassæ effervescens, Potassii bromidum, Potassii iodidum, Liqueur Potassii iodidi compositus, Liqueur sodæ effervescens, and Liqueur sodæ chlorimatæ.

Botany.—In the botanical department of the Pharmacopœia, we find the words *bulbus*, *rhizoma*, and *cormus*, have in several places been very properly substituted for *radix*; which, in the last edition of the Pharmacopœia, was applied indiscriminately to several vegetable organs. This term is still employed to designate the officinal part of *Veratrum album*, but a superficial examination of this substance will convince any one that it is not applicable. The word *fructus* is properly introduced in several places where, formerly, the term *semina* was employed; as in *Anethum*, *Anisum*, *Coriandrum*, &c.

Jalap root is declared, on the authority of "Don, MS."! to be the produce of *Ipomœa Jalapa*. Now it is several years since the plant yielding jalap was described by an American botanist, and declared to be a species of *Ipomœa*, which he named *I. Jalapa*. The account has been noticed by almost every recent pharmacological writer, English, French, German, and American. "In the year 1827, Dr. John R. Coxe, Professor of Materia Medica in the University of Pennsylvania, received, directly from Xalappa, several small jalap plants, in a growing state; and having placed them in his garden, succeeded in raising one with all the parts necessary for a decision upon its botanical character. Mr Nuttall, to whom it was exhibited, had no hesitation in pronouncing it an *Ipomœa*, and described it with the title of *Ipomœa Jalapa* *."

It is, therefore, somewhat surprising that the College should give Mr. Don the credit of discovering the true jalap plant, which is justly due to Mr. Nuttall, and that they should prefer quoting manuscripts to published papers.

Ergot of rye is assumed by the College to be a fungus, and is named "*Aciuula clavus*." In the present state of our knowledge with respect to this product, this decision, to say the least of it, is premature. Botanists are far from being decided on its nature, and one of the latest writers on Fungi (Rev. M. J. Berkeley, in Vol. V., Part II. of Smith's "*English Flora*,") says, "It appears to be only a diseased state of the grain, and has scarcely a sufficient claim to be admitted amongst fungi as a distinct genus. The only way of deciding the point would be to institute inquiries as to the manner in which it commences its growth, as Brongniart has done respecting *Uredo Segetum*. The external coat is subfarinaceous, and very different from any thing I have seen in *Sclerotium*."

Rheum palmatum is still retained in the Pharmacopœia as the mother-plant of the rhubarb of the shops, though the statement is supported by very slender evidence. The principal argument in favour of the dictum of the College, is, *that of all known species of Rheum, the palmatum yields a root which agrees best with our officinal rhubarb*. But it is well known that the Bucharrians declared to Pallas they were unacquainted with the leaves of *Rheum palmatum*, and described the leaves of the true rhubarb plant as being round, with a few incisions on the margin. Sievers also, who travelled four years in the rhubarb countries, decides against the *R. palmatum*. Moreover, the root of cultivated specimens of this species is always found to differ considerably from the rhubarb imported, though these differences are usually ascribed (without sufficient foundation, however) to climate, soil, &c. Our opinion is, that the true rhubarb plant, or probably plants, are yet unknown.

Three species of *Cinchona* bark are mentioned—namely, *C. cordifolia*, *C. lancifolia*, and *C. oblongifolia*; and

* The Dispensatory of the United States of America, by G. B. Wood, M.D., and F. Bache, M.D. 1834. For further information, consult

Journal de Chimie Médicale, tom ix. and x. (for the years 1833 and 1834), in which will be found a drawing of the plant; also the last edition of Guibourt's *Histoire Abrégée des Drogues*.

they quote as their authority Mr. Lambert's work on the genus *Cinchona*. We presume that the College intend, by the above names, to designate the barks known to druggists by the terms *yellow, pale, and red bark*.

To the assumption of the College, that the *Cinchona cordifolia* yields yellow bark (that is, the bark employed in the manufacture of sulphate of quina), we reply, there is no evidence in its favour. Mutis, indeed, says that the bark called by the Spaniards *Quina amarilla* (that is, *yellow bark*) is obtained from *Cinchona cordifolia*; but it must be recollected that the terms *yellow, pale, red, orange, &c.* applied to barks, are merely relative; and we ought not to infer, that because a bark is called yellow in one country, it will necessarily have the same acceptation in another. That the *Quina amarilla* is not our *yellow bark*, and that the *Cinchona cordifolia* does not yield this latter, we think the following facts sufficiently testify:—

1. "Many authors (says Guihout) yet attribute the *true calisaya*," the name by which our yellow bark is usually known in France, "to *Cinchona cordifolia*, in consequence of Mutis having given the name *yellow cinchona* to the bark of this tree; but the authentic specimens of the 'yellow cinchona' of Mutis, brought by Humboldt, prove that this bark is that known in France by the name of *Quinquina Carthagène*; quite different to the *Calisaya bark*."

2. Bergen, a distinguished German writer on the *Cinchona* barks, had access to the collection of Ruiz; and he thus speaks of the *Quina amarilla*:—"The pieces found in this collection marked as *Quina amarilla* (*C. cordifolia*, Mutis), consist of some flat pieces and some fragments of quills, which are quite identical with the foregoing, described hard *Flava*" (the *China flava dura* of Bergen is, as he himself states, and as we can prove, the *Carthagena bark* of English commerce); "and there cannot be the least doubt remaining that the *C. cordifolia* is the mother plant of the *China flava dura*."

3. The *Cinchona cordifolia* grows in Colombia, in the mountains of Santa Fe de Bogota, Loxa, and the ancient kingdom of Quito. Now the commercial outlet for Bogota, Quito, and the neigh-

bouring parts, is Carthagena*, from which place is exported the bark termed in English commerce *Carthagena bark* (by the Germans called *China flava dura*), and which is declared, by the united testimonies of Bergen and Guihout, to be the *Quina amarilla*, said by Mutis to be the produce of *C. cordifolia*; whereas the bark called by our druggists *yellow bark*, and from which sulphate of quina is procured, is produced most abundantly in Bolivia (formerly Upper Peru), in the province of La Paz (more than a thousand miles south of Bogota), and is usually exported from the ports on the western coast of South America on the Pacific, though formerly it was also shipped from Buenos Ayres. "We have been informed," say Drs. Wood and Bache, "by gentlemen who have been long personally engaged in commercial transactions upon the Pacific coast of South America, that the *Calisaya bark* of commerce (*yellow bark* of English druggists) is originally obtained chiefly, if not exclusively, at the Port of Arica, whither it is brought from the interior provinces of Bolivia."

To this testimony we beg to add the following: during the last week we examined the import book of one of our wholesale druggists, and found that nearly all the yellow bark brought to this country for some years back was exported from Arica, Valparaiso, and Lima, and that none came from Carthagena.

We cannot conclude these remarks respecting yellow bark, without quoting the following passages from the Dispensatory of the United States of America, decidedly the best work of the kind yet published in any language. "Authors are by no means agreed as to the particular species which yields *Calisaya bark*. Some, influenced simply by its officinal title of yellow bark, have attributed it to the *C. cordifolia*, because Mutis gave the same name to the product of this species. The British Colleges have fallen into this error, without, however, being aware that the yellow bark which they adopted as officinal was really the *Calisaya*. That it is an error, has been fully demonstrated, as no *Calisaya bark* is brought from those regions where the *C. cordifolia* most

* See the work entitled "*Colombia*," published (anonymously) in two vols. 8vo. 1822, p. 293, vol. i.

abounds * *. A curious mistake on this subject is made by Dr. A. T. Thomson in his Dispensatory. Considering the *C. lancifolia* as undoubtedly the origin of the *pale bark*, and at the same time receiving, without hesitation, the assertion that the *Calisaya* is the product of this species, he has inferred that the two must be identical, and has, therefore, given *Calisaya* as one of the synonymes of *pale bark*; while he has accurately described the true *Calisaya*, but without naming it, under the head of *C. cordifolia* or *yellow bark*."

Neither do we believe it to be correct to ascribe red bark to *C. oblongifolia*. Mutis, indeed, states that this species yields "*Quina Roxa*" (*red bark*); but this *Quina Roxa* has been found by Bergen and Guibourt to be a new kind of red bark, called "*Cinchona nova*." The red bark of European commerce is termed by the Spaniards "*Quina colorada*," and we believe the origin of it is unknown.

Want of space prevents us from entering so fully into the examination of the source of red as we have done with respect to yellow bark, and we must therefore refer those interested in the inquiry to the works of Bergen, Guibourt, and Drs. Bache and Wood. We may add, that as Mr. Lambert does not pretend to an acquaintance with the characters of the *Cinchona* barks of commerce, his work on this point can be no authority; though his collection, in the hands of an able pharmacologist, might be of considerable service.

Kino is still declared in the Pharmacopœia to be the produce of *Pterocarpus erinaceus*. That this is erroneous is proved by the following facts:—*Kino* is brought to us from the East Indies,—especially from Amboyna; whereas *Pterocarpus erinaceus* is not found in the East Indies, but is a native of Senegal, in Africa. Moreover, we have in our possession African *kino* (possibly the produce of the *P. erinaceus*), but its physical characters are quite different from the *kino* of commerce.

Copaiba is said to be the produce of *Copaifera Langsdorfii*; but it is well known that the commercial article is obtained from many species of *Copaifera*: Martius enumerates nine,—Nees Von Esenbeck, fourteen.

Many other articles of the *materia medica* were marked by us for notice,

but those already examined have taken up so much space, that we are under the necessity of here closing our remarks on the *materia medica*; and in a subsequent number we propose examining the chemical portion of the Pharmacopœia.

Micrographia: containing practical Essays on Reflecting, Solar, Oxy-hydrogen Gas Microscopes, Micrometers, &c. By C. R. GORING, M.D. and ANDREW PRITCHARD, Esq.

THE use of the Microscope has of late done such signal service in the advancement of minute and pathological anatomy, in the discovery of so many otherwise invisible tribes in the animal kingdom, and in displaying so variously and so beautifully the perfection of nature, even in what might seem the most insignificant of her works, that it is not surprising there should be so prevalent a desire among all classes of society to become more intimately acquainted with the instrument. To inquirers in medical science the microscope has become indispensable; nor is it possible to appreciate the labours of Ehrenberg, Raspail, Owen, and divers others, who have, in some sense, opened and described a new world to us, without being more or less adepts in microscopical study.

The scientific public are indebted to the authors of the work before us, for much aid in promoting their means of optical research. In the "*Microscopic Illustrations*" and "*Cabinet*" they have supplied abundance of valuable hints for practice: nor will it be found that they are a whit less practical or useful on the present occasion. Dr. Goring exhibits his skill in treating popularly the intricate subject of reflecting and solar microscopes, and the methods of ascertaining the comparative merits of microscopes and engiscopes. Mr. Pritchard gives an interesting account, historical and descriptive, of the oxy-hydrogen instruments (the first we believe that has been published), and has added several practical suggestions which cannot fail to prove valuable. A letter in the Appendix "*on making drawings of microscopic subjects*" from Mr. Bauer, will be read with interest; it is illustrated with figures, as indeed the work is throughout with excellent wood-cuts and engravings. The authors, we think,

have conferred a boon on the votaries and admirers of the microscope: and who is not at least an admirer of an instrument which has achieved such triumphs?

MEDICAL GAZETTE.

"Licet omnibus, licet etiam mihi, dignitatem Artis Medicæ tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

CORONERS AND THEIR JURIES

versus

THE MEDICAL PROFESSION.

THE light that medical knowledge throws on the path of justice is, not unlike many other good things in this world, freely enjoyed without much regard to its true value. Like the air itself, which men fail to hold precious, until they happen, some time or other, to be partially deprived of its use, it seems to have come at length to be considered as truly belonging to political, as the atmosphere is essential to physical, existence. Medical men have so long been in the habit of bestowing their services gratuitously in aid of the law, and have in general so readily obeyed, if not anticipated, the call of the magistrate, that there seems to have been formed a sort of tacit compact, implying that the assistance which medical science is capable of affording in difficult cases coming before the judicature, shall not in any case be withheld.

Luckily, however, there is no such compact in reality,—and the profession may be congratulated that there is not; for a persistence in the course just mentioned has, in the natural order of things, led to a position in the route, from which to proceed further, without some new arrangement, would prove, at least to the parties on one side, a grievous hardship. An abuse, in short,

has been growing up, and has attained at last so serious a magnitude, as imperatively to require consideration how it may in future be best obviated.

Medical science, in reference to legal, has of late made great strides; and that kind of knowledge required for purposes of civil polity has been diligently cultivated, and may now be almost said to constitute a distinct profession. The ordinary acquirements of the practitioner of medicine or surgery, or both, are in themselves insufficient to fit their possessor for a referee in the great majority of civil and criminal cases; other special attainments must be superadded, if the preservation of character and reputation be an object: nor can this be accomplished without additional study, and the outlay of much money and time.

The necessity for such preparation has been for some time recognized in the profession; and a natural consequence is, the laying a higher value on the assistance which can be afforded to the magistrate and the judge. The increasing demands, too, made on our profession, in quarters where a fair remuneration has been thriftily and meanly refused, have created a reaction, salutary inasmuch as it directs attention to the proper value of medical services.

But the community generally are but ill acquainted with these facts: slowly and reluctantly they begin to learn that medical evidence is a thing which of late the legislature has thought worth paying for; and the information rouses them, as if it announced the levying of a new tax. What shifts and devices have been had recourse to, in order to escape the impost, must be familiar to every observer. How to avoid the trouble and expense of medical evidence, and whether the presence of medical men may not be altogether dispensed with on certain occasions, have been the

grand problems discussed among the rate-paying jurymen forming the coroners' courts.

It is almost needless, after the frequent complaints made by our correspondents, and the daily announcements through the newspaper press, to point out the peculiar position in which medical men are at present placed with reference to their public functions as medical jurists; yet a short enumeration of the particular grievances under which they labour may not be without its use, as it may tend probably to suggest the most feasible remedy.

1. It was once the regular rule to obtain medical evidence at any inquest involving a question relative to the nature of the death; of late the practice is the reverse: medical evidence is only sought in cases of absolute necessity—where there is an utter impossibility of coming to a probable conclusion without it. There is a manifest disinclination on the part of both coroners and their juries to allow medical witnesses to be called; the business obviously may be so much more quickly dispatched without entering into scientific inquiry: besides, there is a fee to be paid, which the majority of the jury, who have it in their power to call or not to call the witnesses, are indisposed to countenance—they being, in fact, rate-payers—contributors to the very fund from which the said fee is to be disbursed. Instances of this narrow, niggardly feeling, are frequently exhibited: perhaps we may take leave to notice one as an example. An inquest was held on the 27th ult., in Ebury-street, Pimlico, before Mr. Higgs. The coroner refused to summon the surgeon who had been sent for to the deceased, and who, from having investigated the circumstances of the case, (death by hanging) was prepared to throw every light on the inquiry. It was obvious, moreover, that but for the drawback of the fee, this gentle-

man would have been deemed the most eligible witness: the coroner, however, positively refused to summon him; whereupon the surgeon had no alternative but to remonstrate publicly, as he did, and to announce his intention of applying to the Secretary of State for the Home Department.

2. Another meanness to which the late arrangements have led is this:—Whenever the coroner has any kind of pretext for calling on a medical man as a common witness, he fails not to avail himself of it—as he thus has a chance of procuring the necessary information, without a *special summons*, which alone entitles the witness to his fee. We trust, however, that practitioners will be on their guard against this imposition, and that in all such cases, although they be obliged to give evidence as to matter of fact, they will withhold their professional opinion, unless promised the requisite honorarium.

3. There is yet another gross abuse to be complained of, growing, in great measure, if not wholly, out of the late inadequate measures for providing remuneration for medical evidence,—for we have not only to contend with the griping spirit of coroners, jurymen, and overseers, but with the mischiefs entailed by bungling legislators: the coroner, on determining to have medico-legal assistance in cases in which he cannot help calling for it, issues a *special summons* to as many medical practitioners as he sees occasion to consult; although it is only *one* of the witnesses thus specially summoned who becomes entitled to a fee. This is surely something more than a mere hardship—it is a fraud practised on the members of our profession, which should in no case be silently submitted to. In our present number (p. 554) the nature of the unjustifiable trick thus put upon respectable practitioners, is well exposed by Dr. Ramsbotham; in whose

letter the reader will find a clear exposure of several other points also, connected with this subject.

Lastly, in several instances where medical men have been specially summoned, they have been *refused* the remuneration to which they were by law entitled. But what a remuneration! supposing even that it were in every case promptly and cheerfully paid. A guinea for "giving evidence," and an additional guinea where a post-mortem examination may have been ordered, with or without a toxicological analysis of the contents of the stomach; and should attendance on such terms be declined, a certainty of being mulcted in five pounds sterling! Such are the blessings entailed on us by incompetent and blundering intermeddlers. But we have already sufficiently exposed the circumstances connected with this part of the question.

As to the conduct of coroners and jurymen, in declining medical evidence wherever they can, there seems to be no remedy for it, save in that chastisement which the exhibition of wilful ignorance so richly merits. These people will probably persist in the line they have adopted, until some gross blunder awakes them to a sense of their silly indiscretion. As it is, the coroner's court in ordinary cases is notorious for its precipitate and often nonsensical verdicts; its "temporary derangement," "insanity," "found drowned," &c. have become the butt of well-merited ridicule. But cases may occur, as they often have occurred, where serious injury may be inflicted on accused parties by the rashness of similar awards. Should it prove that such mischief arises through the wilful rejection of medical evidence, we promise, for our parts, not to fail in setting the matter in its proper light; and we doubt not that ultimately, at all events, there will accrue to such con-

duct its appropriate meed of public indignation.

LATE OUTRAGE AT APOTHECARIES' HALL.

MR. CHARLES PENRUDDOCK, the medical student by whom the recent assault on the members of the Court of Examiners of Apothecaries' Hall was committed, was brought up on Thursday before Mr. Alderman Pirie. He had been remanded on the former occasion in consequence of the absence of Mr. Hardy, who was confined by the injuries he had received. This gentleman, however, was sufficiently recovered to attend the day before yesterday. No particulars of importance were elicited in addition to those we stated in our last number but one. Mr. Penruddock was committed, and the several parties bound over to prosecute. The trial, on the charge of felony, will take place at the Old Bailey about the end of February.

We cannot allow this opportunity to pass without pointing out the disgraceful system of insulting the members of the Court of Examiners on their way to the Hall, which has been for some time carried on. Certain persons, headed by some of the chief performers at the "Crown and Anchor" meeting of last year, have collected every Thursday, for several successive weeks, at a public-house opposite the Apothecaries' Hall, where they watch the arrival of the members of the Court, and insult them by the use of the most opprobrious, and sometimes of the most blackguard and disgusting epithets. We have ascertained the names of two "Grinders," who act as ringleaders, haranguing such individuals as they can get to listen to them, and inflaming their minds against the Examiners by every means in their power.

The circumstances are without parallel in this country ; and it is mortifying in the extreme to think that any calling themselves members of a liberal profession should be capable of conduct so much calculated to reflect disgrace upon it. The whole may be traced without difficulty to the working of the "Meade and Wakley" meeting, at the Crown and Anchor, last year. The Worshipful Society ought to apply to the magistrates, as the nuisance has become quite intolerable ; and it is a duty they owe to the public not less than to themselves, to have it effectually abated.

RECENT DISTURBANCE AT ST. THOMAS'S HOSPITAL.

ON Tuesday last a true bill was found against the gentlemen implicated in the late disturbance at St. Thomas's Hospital. The parties (we forbear at present to mention the names) are to be tried at the next sessions.

It is impossible not to regret, on many accounts, the occurrence of this most discreditable affair. That some of the Guy's students acted with unwarrantable violence is quite obvious ; and it would, therefore, have been more judicious to have endeavoured to deprecate, rather than incense, those in whose power they had placed themselves in a moment of youthful impetuosity. As it is, the event has assumed an aspect most formidable as regards the young men themselves, most injurious to the interests of the school, and most distressing to their friends. Some of the young gentlemen have had very bad advisers ; and the part taken by the *Lancet* has done them infinite mischief. It never is either wise or manly to justify what is wrong,—even if that wrong has been committed in the vindication of a right. But how infinitely more unfortunate is it in any one implicated in an affair of this kind

to have such a person as Mr. Wakley mixed up in it. Although, in this instance, he may have forced himself upon them, yet, we ask, had not the parties to whom we allude penetration enough to know that his affectation of interest and anxiety for them was but a trick of our roguish contemporary to serve his own purposes? Did they not perceive that the volunteer advocate and adviser is a mere knave, who makes tools of them for his own purpose? Wakley endeavours to identify himself with the pupils even where they may be wrong, in order to gain popularity and to sell a few copies of his journal ; but in this instance he accomplishes more, for he gratifies a double animosity, viz. his hatred of both the Borough hospitals ; institutions which cannot but be deeply injured if he can goad on the pupils to perpetuate the existing dissensions. As to the rest, no man can be a sincere friend of the students, who adopts that line of conduct which is, of all others, calculated to bring down the greatest rigour of the law upon them, instead of endeavouring to have the angry feelings on both sides soothed, and some accommodation effected.

On the same principle, with reference to the pupil who assailed the members of the Court of Examiners at Apothecaries' Hall, instead of attributing the act to insanity, or momentary excitement (the only real palliatives), Mr. Wakley actually justifies the deed ! and thus provokes the Worshipful Society to let the law take its full course against the delinquent. He says that it is not known what provocation the Examiners may have given the pupil,—as if any provocation could possibly justify such an outrage ; and in reference to our remark, that *his* inflammatory writing tended to lead young men to the commission of violence, he expresses regret that the merit does not in this case

diately and unequivocally
m.

REPORT
OF THE
LEGAL EXAMINATION
OF THE
K OF A HUMAN BODY,
WAS LATELY FOUND IN THE
EDGEWARE ROAD,
MYSTERIOUS CIRCUMSTANCES.

been favoured by Mr. Gird-
he following full and satisfac-
given at the inquest. That
, with the permission of the
lens, had an opportunity of
the mutilated remains the
heir discovery, and was thus
give a deliberate account of
ances.—ED. GAZ.]

y was tied round with a cord,
e arms flat across the abdo-
ezing them deep upon the
and in this manner it was
o a bag. The bag was very
of a very coarse texture, not
ched together at the edges;
re shreds of wood-shavings
to the rugged edges of the
ncipally mahogany, and the
uch saturated with blood at
art.

The body was headless and legless.

On measuring the trunk, its length
from the posterior spinous process of the
seventh cervical vertebra to the point of
the coccyx is 24 inches; in front, mea-
sured from the superior edge of the
sternum to the inferior edge of the sym-
physis pubis, it is 21 inches. The skin
is fair, and a considerable layer of fat
exists under it throughout. There is
an unusually small quantity of hair, of a
light colour, on the pudenda; the pu-
denda want their usual external develop-
ment. There is a slight ecchymosis,
about the size of a pin's head, on the
right labium. The carunculæ myrti-
formes were apparent, and a slight
abrasion was seen at the posterior edge
of the vagina. The breasts are some-
what corrugated on the surface, the
skin not now being so much distended
over them by the plumpness beneath,
as at an earlier period of life it must
have been: there is no hair in the axilla.
There is not the development of the
nipple, nor are there the striated marks
on the surface of the abdomen, nor does
there exist any separation of the recti
muscles, indicative of the female having
ever been pregnant.

The hand is a full woman's size, and
dirty; there is no mark of needlework
on the left fore-finger; the mark of a
ring exists on the left ring-finger; the
nails of the fingers of both hands are
blue towards the tips; the left, how-
ever, has to that superadded on all four
a red streak immediately behind the
union of the nail with the flesh; the
muscles of the arms were rigidly con-
tracted. The length of the arm, mea-
sured from the acromion point to the
tip of the middle finger, is 30 inches.

There are no marks of violence on
the body, excepting on the right side of
the abdomen, two inches above the
groin, there exists a superficial cut, in a
slanting direction, removing the skin an
inch and a half. There are no marks of
medical treatment. She has not been
bled lately, nor blistered.

The head is severed from the trunk
anteriorly, about three inches above the
sternum. The fifth cervical vertebra is
sawn through, leaving only about the
tenth of an inch of that bone.

The legs are cut off immediately un-
der the hip-joint. The cut does not
present a ragged appearance. The
thigh bone on both sides, about an inch
under the trochanter, is sawn from

within outwardly half through, and then broken off. A superficial cut on the left thigh exists, running for three inches parallel to, and about one inch distant from, the one that severs the limb. A similar cut exists on the right side of the neck.

On opening the body, the viscera presented generally this remarkable appearance—they were completely exsanguinated, no congestion in the lungs, no coagula in the heart, no blood flowed, nor were there any bleeding points in the liver, or the spleen, when cut into. All these organs presented a healthy appearance, excepting one or two points of adhesion observed on the pleura, the result of some long preceding inflammatory action; there was no effusion in its cavities. The stomach was about a third part filled with fluid and half-digested matter; pieces of meat could be detected, a little pastry, and it had a slightly spirituous smell. In the smaller bowels was a considerable quantity of the pultaceous matter called chyme, and from them could be traced, proceeding along the mesentery, the lacteal vessels filled with chyle. The surface of this portion of the intestinal canal had a slight purplish blush on its outer surface, and there was scattered over it small dark purple spots. The gullet presented internally a healthy appearance. The bladder was void of urine, and rigidly contracted.

Our attention was now arrested by the remarkable fact, that this female had no uterus. The vagina was about two inches long, and terminated in a *cul de sac*, having a slightly puckered appearance, where ought to have existed the os uteri; the ovaries existed in a fold of the peritoneum, on each side of the brim of the pelvis. The right ovary had a fibro-cartilaginous tumor attached to it, the size of an almond; and the left had a hydatid, about the same size. The fimbriated extremities of the fallopian tubes were not loose, but were matted down to the peritoneum; and tracing their course along the broad ligaments downwards into the basin of the pelvis, they were found to be joined behind the bladder by the round ligaments of either side, proceeding in their usual course from the inguinal ring; and the point of junction of those four ligaments was indicated by a slight fulness, and puckered, flat, longitudinal band, occupying the natural position of the uterus.

REMARKS.—The female, from her appearance, is supposed to be between thirty and forty. Her height, on comparing the length of the trunk and the arm with the length of the trunk and arms of two living women, lead me to suppose it to have been from five feet seven to five feet eight; the mark of the ring upon her finger, that she had been married. The appearance of her hands would lead me to conjecture her as a woman engaged in household work. The bloodless state of the body induces me to consider that the mutilation must have taken place shortly after death. The healthy state of the gullet proves that no acrid poison had been taken, and the contents of the stomach and bowels that food had been taken not many hours previous to death. The absence of disease internally, and no marks of medical treatment externally, indicate her death having been a sudden one, and in all probability not preceded by disease. The remarkable peculiarity connected with the sexual formation of this female, will go far to establish her identity. This woman could never have been subject to the periodic illness of her sex. Taking every circumstance into consideration, I repeat that I think the death must have been a sudden one. Had this sudden death been natural, it must have been by apoplexy; and supposing that to have been the case, still the throat must have been cut shortly after death, to account for the bloodless state of the viscera.

In addition, I have to state that the stomach and smaller intestines were examined by Dr. Hunter Lane, who found nothing deleterious in them.

GILBERT FINLAY GIRDWOOD.

January 5, 1837.

ON THE PREVALENCE
OF
CALCULOUS DISORDERS AMONG
SEAMEN;

IN REPLY TO MR. COPLAND HUTCHISON.

To the Editor of the Medical Gazette.

SIR,

MR COPLAND HUTCHISON has preached a rather lengthy sermon from a short

text. The report of my observations at the Medical and Chirurgical Society was so compressed that it omitted three-fourths of what I said, and did not clearly or exactly represent my statements in some particulars*. In the first place, I disclaimed all idea of putting my *opinions* in competition with Mr. Hutchison's laborious *researches*; but that I had an *impression on my mind* (these were my very words) that men had often been invalided from the service while actually affected with calculous complaints, and who might have repaired subsequently to civil hospitals. I never said that seamen, when known to have calculus, *were invalided and sent to civil hospitals*. How many hundreds have laboured for years with stone in the bladder, and only presented symptoms of bad health, till the sound was introduced and the calculus discovered!

The supposed insult to naval hospital surgeons falls to the ground; or if it can be so construed, I take it to myself, for I candidly confess, that at no period of my naval life would I have undertaken, whether afloat or ashore, the dark, difficult, and dangerous operation of lithotomy, of which the naval surgeon, according to Mr. Hutchison's own shewing, can have no practical experience. But let us see whether there are any apt illustrations of this supposed insult to naval hospital surgeons. Within my own knowledge, two naval surgeons (Sir V. Duke, and Mr. Evan Edwards, one of whom was himself a naval *hospital* surgeon, and consequently jealous of the honour of the staff,) became affected with calculus, and after many years of suffering submitted at last to the knife. But to whose knife? Did they go the Naval Hospital at Plymouth, to be operated on by Sir Stephen Hammick? No. To Haslar, where Mr. Vance (an excellent surgeon) was in his prime? They did not. Did they repair to the Royal Hospital at Deal, in order to give Mr. Copland Hutchison an opportunity to flesh his maiden gorget in their bladders? Not they, indeed! They very prudently came to the metropolis, and submitted themselves to men—who had been brought up in hospitals—who had for years been in the *habit of assisting*

others in this formidable operation—who had been in the long habit of dissecting the parts concerned in lithotomy—who had been in the habit of teaching anatomy and surgery for years—and who, after all this training, had been in the habit of operating for stone on the living body. How will this portrait apply to the naval surgeon, who, I admit, is a good operator in general surgery? I may not have had the education, the talents, the intrepidity, the ambition, of Mr. Copland Hutchison; but I had a conscience in my breast which would not have permitted me to peril the life of a fellow-creature, by undertaking the operation of lithotomy, which requires years of preparation and practice to effect it *well and safely*—and all for the *doubtful* chance of obtaining some *éclat* for myself. If this declaration be taken as an insult to naval surgeons, it is directed against their vanity, and not their humanity. The art of cutting for the stone cannot be learnt by *intuition* in the navy no more than in any other place; it demands a very long apprenticeship, which few can undergo, even in civil life.

But to come to the statistical question itself. Dr. Gordon suggested, and Mr. Earle and others confirmed, the real cause of infrequency of stone in seamen—namely, the period of life at which they enter and leave the service in general. Mr. Earle stated that the overwhelming majority (more than five-sixths) of lithotomy operations in St. Bartholomew's Hospital were under the age of 12, and above that of 45 or 50 years. The infrequency of stone, therefore, is not peculiar to seamen, but to all people within the above periods, and who lead active lives. As for the diet, the grog, the sea air, the tobacco, and many other alleged causes for this immunity from stone, they are mere creatures of the imagination.

In respect to my friend Mr. Hutchison's suspicion that I had been reading Roderick Random just before I went to the Society, I confess my partiality for that amusing production, and that, had I much dull time on my hands, I am not quite sure that I would not prefer Smollett to Hutchison—I am, sir,

Your obedient servant,

JAMES JOHNSON.

* The report to which Dr. Johnson alludes appeared in the *Lancet*, not in this journal.—E. G.

NOTE FROM DR. WEATHERHEAD TO DR. JOHNSON.

Royal Med. and Chir. Society,
Dec. 28, 1836.

Dear Sir,—From being much occupied during the last week in preparing to remove my dwelling, I did not see either of the weekly journals.

I write to say, after perusing the *GAZETTE*, that I was not the "friend" who communicated any thing to Mr. Hutchison on the subject of the debate.

I felt assured that it never was your intention to cast any reflection on that department of the naval service to which you belong; and, indeed, you disavowed the bare idea of it *de plano*.

Very truly yours,
G. HUME WEATHERHEAD.

Dr. Johnson, &c. &c.

P.S.—So far from asserting that men were sent from naval hospitals to civil hospitals for the operation of lithotomy, I distinctly stated that I was present at an operation for stone in Haslar Hospital, the patient being a gunner of a ship in ordinary at that port.

J. J.

THE MEDICAL WITNESSES' ACT.

ITS IMPERFECTIONS AND INJURIOUS TENDENCY.

To the Editor of the Medical Gazette.

SIR,

As proofs are daily occurring of the Medical Witnesses' Act being misinterpreted by coroners and overseers, as well as by members of our profession, I trouble you with the following notice of two cases that came under my own observation, where it seems the coroners exceeded their power, in summoning more medical witnesses than the law authorizes them to do, and in giving orders for the payment of fees, which in one of the instances has been successfully resisted.

More than a month ago I was requested by my friend Mr. William Pater, of the Commercial Road, to accompany him to the house of a neighbour, whose servant had secretly delivered herself during the previous night of a mature foetus. Until his arrival the family was ignorant of what had taken place; but notwithstanding the girl's strong asseverations to the contrary,

he was convinced she had recently born a child; and after much search it was found. Leaving the infant exactly in the position in which it was discovered, and refraining from any further investigation for the present, he sought my advice. It was, of course, necessary that an inquest should be held; and anxious not to take the entire responsibility of the medical portion of the inquiry upon himself, he wished me to be associated with him.

On the case being made known to Mr. Baker, the coroner for the district, he issued two distinct summonses, one to Mr. Pater, the other to myself, directing us to proceed to the examination of the body anatomically, and to attend at the inquest to be holden the following day. We acted in obedience to the command, gave our evidence before the jury, and each received an order on the overseers of Stepney parish, signed by the Coroner, for the fee of two guineas, as awarded by the Act. When these orders were presented, the parish officers refused to pay more than one, on the ground that Mr. Baker had overstepped his authority in summoning two medical men. Mr. Pater appealed to the magistrates at Lambeth-street Police Office; but, as it was a novel case, they declined giving their decision until they had looked over the act of parliament more critically. The further hearing was fixed for last Monday, when Messrs. Hardwicke and Combe, the presiding magistrates, decided that the double order had been issued by the coroner *illegally*, and that the overseers were fully justified in refusing payment to more than one.

Four or five weeks before the inquest just mentioned was held, I was summoned by Mr. Payne, the city coroner, under circumstances very nearly similar. A newly-born child was found dead; suspicions attached to the mother; and the medical man who first saw it being desirous of my opinion, Mr. Payne summoned me before the jury met, directing me to attend and give evidence. Both my friend and myself were examined, and an order for the payment of the fee to each of us was signed by Mr. Payne, and honoured by the parish officers.

Thus, sir, two coroners, both practising lawyers, have, it would appear, misunderstood the power with which the act invests them, and have been led into the error of giving an order for a fee which cannot be recovered if resisted. That Mr. Payne believed he had legal authority for ordering payment to two medical men, provided he thought it necessary to summon two, I gathered from a conversation I had with him at the time I appeared before him; and it was the impression I had derived

from that conversation that induced me to recommend an appeal to the magistrates at Lambeth-street.

This construction of the Act by Messrs. Hardwicke and Combe (and on an attentive perusal of it I am persuaded their decision is correct), may perhaps bear hard on our profession, because it is impossible for any medical man to know whether he is the *only one* summoned, or whether the coroner may not have required the attendance, either through mistake, ignorance, or design, of two, or perhaps half a dozen of the profession; should such be the case, only *one* would receive payment, while each would be liable to a fine of five pounds if he did not attend according to the order. Under the old system,—certainly vicious to the highest degree,—the coroner had neither the power to compel the attendance of a medical witness, nor to punish for disobedience of the summons;—under the present, he may issue a summons to a dozen, having authority to remunerate one only; while at the same time every individual called upon would be liable to be fined if he did not make his appearance. This is surely a bungling remedy for a previous glaring defect.

In another respect the Act is most faulty as regards the wording. It gives the coroner authority to call in the aid of any medical man in actual practice living “in or near the place where the death has happened.” And the jury, when assembled (provided they are not satisfied with the medical evidence before them), may require the assistance of as many medical men as they choose to name, without any reference to their residing “in or near” the spot. Thus, on the one hand, the extent of distance implied by the indefinite term *near*, is left to be construed according to the caprice of the coroner or summoning officer; and, on the other, the jury may send for any eminent practitioner from any part of the country, affording him the very liberal fee of two guineas if he attend, and rendering him liable to a fine of five pounds, provided he decline availing himself of their invitation. Indeed, this short piece of legislative enactment is so ill calculated to remedy the evils previously existing, that I quite agree with the magistrate at Lambeth-street Police-office, who said he had little doubt but that in the next session of parliament a bill would be introduced to amend this Act, and place it on a more practicable footing.

One of the alterations I would propose should be, that instead of the words “in or near,” a limit of distance should be specified; and that no practitioner should be brought further than five miles from home

without an extra fee per mile being paid him, together with travelling expenses at the same rate as is allowed to the coroner;—and another, that the coroner should be authorized to require the attendance of *two* medical witnesses *independently of the jury*; for it is evident that in cases of suspected poisoning, infanticide, and many others, the concurring testimony of at least two professional persons is not only desirable, but should be had if possible.

Provided the Act be left as at present, see what must result. Let us suppose the coroner to direct an analysis of the contents of the stomach before the jury meet; either the medical men summoned to attempt this difficult operation will not think himself competent to do it, or will shrink from the responsibility, and, failing to obey, he will be fined five pounds, or he will proceed to the investigation, assisted by a friend, who will not receive remuneration, and therefore he will lay himself (perhaps unwillingly) under considerable obligation to his friend; or, lastly, he will undertake it single-handed, and necessarily do it imperfectly; for no one will contend that a delicate chemical analysis can be properly performed without competent assistance. His testimony will, in that case, neither be so full nor useful as it might.

Again, suppose the coroner merely issues his summons for attendance, without ordering an inspection of the body; and the jury having met, the medical witness declares his inability to give evidence unless an anatomical examination is made. The jury direct it should be done, and nominate a second gentleman, to whom *they* have the power of granting remuneration. The inquest must be adjourned, probably, till next day; and every body concerned loses much time, which might have been avoided if the coroner could have taken upon himself conscientiously to enforce the attendance of two professional men in the first instance.

It is not impossible, however, that, in such case, the majority of the jury (impanelled against their will, and anxious to make no greater sacrifice than they are absolutely obliged to do, or perhaps not wishing to burden the parish rates with extra fees, they themselves being rate-payers) may decline calling in another opinion, or requiring any anatomical inspection at all. If they are satisfied with doing their duty in a slovenly manner, the coroner has no alternative but to bow to their decision; for however necessary he may consider additional testimony, the law does not empower him to obtain it against the vote of the majority of the jury; and the ends of justice are defeated.

These are some of the inconveniences

likely to arise from the operation of this ill-digested statute. Another annoyance that has been already felt, consists in making the *giving evidence* the *sine qua non* to entitle to remuneration. Medical men have been summoned by the coroner, have been kept waiting for hours in the inquest room, and have at last been told by the jury that they are quite satisfied as to the cause of death, without medical testimony. The practitioner, under such circumstances, cannot claim his fee, and of course it would not be paid.

Both the instances I have noticed above were peculiar, and possessed points of interest in a medico-legal view. In the last, a medical practitioner saw the infant very soon after its birth, while the body was yet warm, and tried to re-animate it by inflating the lungs and other means. Mr. Payne's object in summoning me, appeared to be to learn whether, after these unsuccessful attempts at resuscitation, a *post-mortem* examination would throw any light upon the question whether the child was born alive.

In the other case, it was evident that the infant was expelled living, although it had never breathed, and that it died from bleeding through the umbilical vessels. It was found with its head downwards, in a covered slop-pail, nearly full of bloody water, in which also there were two small coagula and a quantity of indurated faeces. The funis was torn asunder at the distance of eight inches from the umbilicus, and neither was there a ligature around it, nor any appearance of one having been applied. As soon as I saw the mother, I made a search for the placenta; but it was not to be found in any of the cupboards or boxes in the room. Suspecting it might still be in utero, I examined the vagina, and discovered the torn end of the funis, just within the vulva: I removed the placenta from the uterus by the introduction of the hand. It was partially adherent, and almost entirely within the uterine cavity. The whole length of the funis was only 13 inches, and the two lacerated ends tallied most exactly. Although at least eight hours had elapsed between the birth of the child and the extraction of the placenta, there did not appear to have been more blood lost than in ordinary labour.

From the girl's statement, and corroborative circumstances, it seemed that, feeling a supposed inclination to evacuate the rectum, she sat upon the pail for that purpose, when, the child being rapidly expelled, and the uterus strongly embracing the placenta at the same moment, the funis was put violently on the stretch by the weight of the falling body, and the jerk snapped it.

That the child was born alive, I think was clear, from the fact of its body being almost bloodless; the large vessels were completely empty, and the viscera very much paler than natural. There was also a small quantity of bloody matter, exactly such as the pail contained, found in its stomach; a convincing proof that it was not dead before its birth. But as the lungs had never admitted air, the coroner laid it down as a principle, that the child could not be said to have lived *ex utero*; and a verdict of still-born was returned.

I am aware that there is a question among physiologists, as to what should be considered sufficient to constitute a live birth; whether a few tremulous throbs of the heart are enough, or whether the infant must actually have respired; but I cannot agree with the doctrine that, if a foetus be expelled from the uterus into a fluid in such a manner as to preclude the possibility of its breathing, while the unprotected ends of the broken funis permit the blood to flow out of its body rapidly (supposing the heart to be in action) the single circumstance of the lungs never having admitted air, will warrant us in considering it as still-born.

That the girl did not intentionally murder the child, both Mr. Pater and myself were convinced; but that she was guilty of causing its death by most culpable neglect, I think cannot be questioned.

I am, sir,

Your very obedient servant,

FRANCIS H. RAMSBOTHAM.

14, New Broad-Street,
Jan. 2, 1837.

ON SELF-SUPPORTING DISPENSARIES.

IN REPLY TO MR. H. L. SMITH.

To the Editor of the Medical Gazette.

SIR,

I SHOULD be very much disposed to allow the letter of Mr. H. L. Smith, which appeared in your last number, to remain unnoticed, but that were it to be so, some who have not paid much attention to the subject on which he writes, might be misled by it. I cannot certainly reply to the "christian charity" of the man who is so liberal in charging his opponents with *prejudices, misrepresentations, moral cowardice*, and the want of "*honest minds*;" these are unanswerable arguments, and I leave your honest correspondent to the full enjoyment of them. To the essential part of his letter I can and will apply myself; for—

“ ————— now more bold,
The Tempter, but with show of seal and love
To man, and indignation at his wrong,
New part puts on.”

If I can comprehend him, Mr. S. wishes me to understand that he believes there are two things in existing circumstances very prejudicial to the interests both of the community at large and of the medical profession. The first is, “the dealing in human life on the principle of contract,” and the second, “competition.” That these are evils we are all agreed; there is no dispute on this subject,—it is on the question of what is the best remedy for them that difference arises; and (though at the risk of being said to want an “honest mind”), I shall endeavour to prove that Mr. Smith has not found this remedy.

My opinion on this subject, sir, is not a “prejudice,” nor has it been hastily formed. The plan of self-supporting dispensaries, as they are called, because they are *only principally* supported by charity, has now been for some years before the profession; during which I have considered it carefully, and I may add “honestly,” for I have had no private end to serve.

If the “contract system” be “an evil so great as to be unendurable to Christians,” it should be swept away at once—not to be revived in any shape. Mr. Smith, however, notwithstanding his professed detestation of the principle, is endeavouring to perpetuate the evil under another form; for is that which he recommends the less a contract because “the annual payment is four shillings and four pence for an individual,” than if it were 200*l.* per annum for some hundreds or thousands? It is the same principle differently applied, and in no degree less an evil than the system reprobated. But Mr. S. will say it is, because, under his plan, the poor man may choose his own surgeon, and may change him if he please. Let Mr. Smith answer this question truly, and then get out of the difficulty it involves if he can. Was he not asked, at the first meeting on this subject at the Newington School House, how many surgeons he proposed should be attached to the institution he recommended for the Southwark district; and did he not in reply say “four or six of the seniors, and that the juniors might become attached to it as they should become worthy of it?” He did make such a reply, and I was indignant at the humbug so glaringly apparent in such a statement, conjoined with that he had just before made, that his plan would enable a poor man to choose his own surgeon; and this, too, was the plan he had the modesty to propose to some 30 or 40 surgeons of a district in which there are between 2 and

300! I, sir, am a junior surgeon; and I could not but feel grossly insulted on being told, as by implication I was told, some seven or eight years after receiving my license to practise, that I was unworthy to attend the poor. The effect produced on my mind by these words of the “friend of his profession,” will never be erased from it:—all who were present can bear testimony that I do not misrepresent him. So much for the principle of contract as recommended by Mr. Smith, which is not to be despised, when monopolized by four or six seniors! In what way Mr. S.’s dispensaries will put an end to competition amongst medical men, he does not condescend to inform us: he does say “he has suggested a judicious system of co-operation amongst them;” but how will his plan secure this? What is there in it to prevent the juniors of the profession, thrown upon their own resources by exclusion from working his “judicious system of co-operation,” from combining to attend the poor for three-fourths, half, or one-fourth of a penny a week? “They cannot dig,—to beg they will be ashamed;” but of course they will be nothing loth to follow the example set them by their seniors. I write to you as an individual, but I can assure Mr. S. that the members of the British Medical Association (and I have no doubt the whole of the profession) will duly appreciate the attempts made by him to uphold the dignity and respectability of his brethren by vilifying them with accusations of ruining the poor, by harshly enforcing payment of extortionate charges; and the attempted libel contained in the following passage of his letter:—“The craft is their status, and they are naturally prone to *mystify* and *misrepresent* every attempt to liberate their dens of drugs, dregs, and darkness, from the thick clay with which they are covered.” If the animus which caused this nonsensical sentence to be penned be a sample of that with which Mr. Smith would legislate for the profession, the less he meddles with the subject the better; and if his promised scheme is to partake of this spirit, I would strongly advise him to withhold it, if he do not wish to increase the disgust entertained by the mass of the profession at his attempts to vilify and degrade it.

The misquotations and torturings of Dr. Webster’s speech require some comment. I need not, sir, tell you, or your readers, that the paragraph so shamelessly applied by Mr. Smith to his dispensaries, was not Dr. Webster’s; it was the quotation from the Address of the Southwark General Practitioners’ Society, which you had the kindness to publish for me in No. 7 of the present volume of the MEDICAL

GAZETTE: Mr. Smith *may* not know this.

Mr. Smith "would like to be told, what have Poor Law Commissioners to do with affairs that do not belong to them," (nothing, certainly!) and he goes on to say, that "the Foreign Office would be as much in place giving directions on the parish constabulary, as the Poor Law Commissioners have been in their interfering in this matter at all." This may be very true; but it is a matter of too much notoriety that the Poor Law Commissioners have interfered in this matter, and that very largely too, for Mr. Smith to have the audacity to say they have not. If he have any doubt, let him refer to their recently made Second Annual Report, in which he will find their interference avowed, and a justification attempted. Dr. Webster was then right in saying what followed, as were the gentlemen present in applauding what he said, even if some of them should have been (though I do not admit they were) "surgeons to clubs allowing them considerably less (than 4s. 4d.) per annum for each person." When Mr. Smith was at the Newington meeting, before spoken of, the chairman inquired what was the rate at which clubs were usually contracted for. This rate was said by a surgeon of a club to be very low; but this gentleman forgot to add, what my friend Mr. Howell immediately suggested, that "surgeons in making their calculations for these contracts, also calculate on not having to attend above one-third who may become sick, of those whom they contract to attend if required;" and such is the result practically, that two-thirds of the members of these clubs never call upon the surgeons of them for attendance, but employ their own private surgeons in preference: the great object gained by the appointment of a surgeon to a club being the prevention of imposition by feigned illness, the greater portion of these clubs affording to their members a weekly stipend during illness. But would these be the circumstances of a surgeon of a penny club or dispensary, not having any advantages to offer to its members other than the affording them medical aid when sick? Would they neglect to call upon him for that which they were told they had fully paid for? And by what a payment! Does Mr. Smith, in the simplicity of his heart, really believe, or expect any one else to believe, that this penny a week can be a sufficient remuneration for the skill, time, exertions, and anxieties, of a senior medical man? If so, what may the juniors expect?

It is also important to inquire who are the persons to whom this ill-paid-for attendance is to be given? Will the necessitous poor subscribe to these institutions?

Most certainly not, for every penny they can obtain is wanted during health. But say the Poor Law Commissioners, "voluntary kindness and *charity* will *perhaps* often supply the amount!" If it should, what becomes of the independence of the labourer? And if it do not, what resource has he, restricted as the Commissioners themselves now admit relief to be? Will the improvident join these institutions? No; for they have no thought beyond the present; and they will not easily be induced to pay for what they may never want. In the parish of St. Pancras the plan was tried by nine medical gentlemen of some standing; but they could get no patients: the poor could not, the improvident would not, pay; and the attempt died at its birth. At Portsmouth several medical men tried a similar experiment, and with a similar want of success, from the indisposition of the labouring classes to become paupers. Dr. James Copland was the consulting physician of the present Marylebone Dispensary; and I have been authorized by him to tell my friends that he was compelled to withdraw his name from the institution, in consequence of finding that really poor persons did not come to it, but that the patients were such as ought, and could well afford, to pay their own medical men. These are facts which are better worth consideration than any vague assertions as to the utility of these things: they may be useful enough to those who, by means of them, have got into practice; they never could have obtained without them; but it is not by this reason that the mass of the profession will be induced to support them.

What ought to be the remedies for the many existing evils, I am not now disposed to inquire, as this paper has already exceeded what I intended should be its limits: it will have effected its purpose, if the absurdities of Mr. Smith's plan of reform! have been pointed out. At a future time I may be disposed to go further into the subject; until then, sir, I am,

Your obedient servant,
W. EALES.

Southwark, Dec. 27, 1836.

EXAMINATIONS AND CONDUCT OF THE EXAMINERS AT APOTHECARIES' HALL.

To the Editor of the Medical Gazette.

SIR,

HAD it not been for the recent outrage at Apothecaries' Hall, I should not have offered any observations on the letter of your correspondent, at p. 428, who is still

designated a "Student," though it appears that he passed his examination nine years ago, and must, consequently, be upwards of thirty years of age.

Being a very old member of the Society of Apothecaries of London, I have been a not inattentive observer of the proceedings of the Court of Examiners; and I think there are so many circumstances in that letter, unadvisedly and incorrectly stated, that I am induced *now* to make a few comments upon it. Under ordinary circumstances, I should have let such absurdities find their own level; but as such unadvised and incorrect statements, when inserted in *your* periodical, may be considered as possessing some authenticity, and as they are calculated to make the better-minded class of students, and practitioners in general, think less worthily of the Society of Apothecaries than they deserve, I have determined to point out some of the passages which I think objectionable.

Your correspondent, in the first place, gives us a very strong opinion respecting the rejection of a candidate, some time ago, which, he says, was "a positive injustice on the part of the *Hall*," meaning by that word the Court of Examiners, for the *Hall*, in its collective sense, had nothing to do with the affair. And he founds this opinion upon his own judgment, "for he had the pleasure of seeing him examined twice." Now though I did not hear him examined at all, I feel quite assured that no injustice was done by rejecting him; and I will tell your correspondent why. But, in the first place, let me ask by whom were these two examinations made? by a *grinder*, who had been preparing him for some time for these examinations? or was it by a disinterested individual, who had only at heart to elicit the actual amount of information and ability which the student possessed?

I am told that it is a very common practice with the *grinders*, to tell their pupils, "you will be asked such and such questions, and you must make such and such answers:" the pupils, therefore, expect this; and when they find that the examination before the Court takes a very different course—that questions altogether of a different nature are asked, it is not surprising they are unprepared to answer them, and that, in fact, they frequently shew utter ignorance upon subjects of the greatest importance. Can it, then, be wondered at, when a student has been thus losing his time in preparing for a particular kind of examination, which probably will not be touched upon, instead of gaining a thorough knowledge of his profession—can it be wondered at, that he should find himself rejected?

That this was the case with the indivi-

dual in question, there seems to me to be no doubt; if it had been otherwise, the uproar then made would not have been allowed to die away so soon. Why was not a mandamus applied for, as was threatened?—because the young man knew that he had not given such answers to the Court of Examiners as were satisfactory, or could authorize a mandamus to issue. Or, if any wrong or injustice was committed, why was not a complaint made to the Court of Assistants? The Court of Assistants of the Society of Apothecaries, by whom the Court of Examiners are elected, would, on application made to them, have inquired into any injustice or wrong committed by any member of the Court of Examiners, and whoever was proved to have acted unjustly and contrary to his oath, would unquestionably have been removed from the Court. But neither was the King's Bench moved for a mandamus, nor the Court of Assistants applied to for an inquiry, and why?—simply because the candidate *knew* that he had not a leg to stand upon—that his examination was perfectly fair, and even lenient—and that he was most justly rejected.

Your correspondent afterwards complains of the conduct of the beadle—whether with reason or not, I cannot tell; but this I can tell him, that the beadle, like every other officer and servant of the corporation, is amenable to the Court of Assistants, and would infallibly be removed from his office upon the requisite proof of his having been guilty of misconduct. What the author means "by the manner the *Company* * behaves towards students now," I cannot conceive. Has the *Company* ever been applied to on account of, or acquainted with, "the not-over-civil" conduct which has annoyed your correspondent?

He complains that "the names of the Examiners are not known to the world by any scientific works, and by their not being among the heads of the profession." As there are three grades in the profession, of which the apothecaries are content to be the third, I do not know how the Court of Assistants can select any of the heads of the profession to be members of the Court of Examiners; but in the present list of Examiners are to be found the names of two gentlemen who have very much distinguished themselves, both abroad and at home, as army surgeons. There are several who are members of eminent literary and scientific clubs and

* The apothecaries were incorporated by King James I., by the title of Master, Wardens, and *Society* of Apothecaries of London; and the arms, crest, and motto, were granted, by the Herald's College, to the *Society*.

associations; there are two, who, if we may judge from the passages quoted, extracted, and appropriated, from their respective publications, are well known to the profession by their scientific works; and every individual member possesses more than enough of literature and science to raise him high above the *οἱ πολλοί*.

Your correspondent fancies that the Court of Examiners "cannot keep a candidate back six months, if he is rejected in classical Latin." In this he is miserably mistaken. It was because the Court does possess this power, and because there were so many rejections of candidates, in consequence of their inability to translate Celsus and Gregory, that the Court instituted the preliminary examinations in Latin medical classics. These preliminary examinations are not made before the whole Court; if they were, and the candidate could not pass, he would be prevented by the *Act of Parliament* from presenting himself again for six months. But the examinations take place before two or more members of the Court, in order to spare the pupil, if he cannot translate Latin properly, this six months' rejection. That these preliminary examinations have not answered the intention so well as was expected, I am much afraid; but it is chiefly owing to the malignant influence of the *grinding system* that it has failed, and perhaps greater strictness in these examinations would be useful.

Your correspondent goes on to say, "Should they reform, no one wishes the *Worshipful Company* less evil than myself; but should they continue their oppressive regulations, I shall rejoice most heartily if the University puts an end to their pretensions." Having failed to prove *oppressive regulations*, it may fairly be asked whether your correspondent is duly acquainted with any of the regulations of the Court of Examiners? I believe he is not, but that he argues from what he has heard, and not from what he knows. As to the University putting an end to their pretensions, *he ought to know* that the University has no such power. An act of parliament may, indeed, repeal the Apothecaries' Act of 1815, and may give to the University the power which is now lodged with the Society of Apothecaries and its Court of Examiners; but till parliament does repeal the one and constitute the other, the University of London possesses no more power than does the Royal Medical and Chirurgical Society, or the Linnæan Society, or any other society subsisting only by the King's charter; for, fortunately, the King's charter cannot set aside, or abolish, an act of parliament.

SCRUTATOR.

Wednesday 4	24 36		30.20 30.24	

Prevailing wind, till the morning of 2d, N. and N.W.; since W. and S.W.

Generally cloudy till the 1st inst.; since generally clear, except on the 4th. A little snow fell on the 29th, 30th, and 31st ult.

The sudden and great fall of the thermometer on the morning of the 2d, has not been equalled since February, 1830; the rise on the same day was even more rapid. The thaw has continued, with the exception of the night of the 3d, and the quantity of snow is gradually diminishing.

LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE XVI.

Births of Children medico-legally considered—MATURE and IMMATURE BIRTHS—Legal distinctions—Privileges connected with the Birth—Viability in French law—Fama clumosa—Early instances of Maturity—Signs of sufficient Maturity—NATURAL and MONSTROUS BIRTHS—Legal Definition of Monsters—Table of all known Monstrosities, with Remarks—Headless and Brainless Monsters—Double Monsters—Parasitical Fœtuses—Supposed case—Transposition of the Viscera—Question of moral peculiarities connected with that state.

THE medico-legal considerations connected with the births of children are numerous and highly important. Births are mature or immature, natural or monstrous, single or plural, præmature or retarded, live or still, legitimate or illegitimate, &c. The determination of the fact in all such cases chiefly depends on medical evidence, and it is easy to conceive how much the result may affect the peace and welfare of families, and the safety and honour of individuals.

Mature and Immature Births.

The terms mature and immature suggest the idea of a certain degree of growth of the fœtus, without any immediate reference to the time at which it is born. Mature has, indeed, another correlative in

the term præmature, which includes the latter idea; but with this at present we have nothing to do. By maturity, as compared with immaturity, is implied such a degree of development in the fœtus as is consistent with the power of continuing an independent existence. It may be more or less complete, and in so far recedes from or approaches to the state of immaturity. I have already described the characters which mark the mature infant*, when I also gave an account of the progress of development in the fœtus, up to the attainment of intra-uterine perfection. On that occasion, I used the term in a more strict sense than I shall now do; for, strictly speaking, any thing short of that maturity just alluded to should constitute immaturity; but the limitation now introduced will obviate any charge of inaccuracy. We shall, therefore, inquire what degree of maturity is sufficient for extra-uterine life.

Legal distinctions.—It ought to be premised that our laws take little or no cognizance of the maturity or immaturity of the infant at birth; if it be born alive, and not a monster, (and both these facts are understood with great latitude,) it is generally sufficient for every legal purpose. The circumstance of birth merely, confirms in certain cases very important privileges acquired at an earlier date; for an infant in its mother's womb, or *ventre sa mere*, to use the legal phraseology, is supposed in law, for many purposes, to be already born. It is capable of having a legacy, or a surrender of a copyhold estate made to it. It is enabled to have an estate limited to its use, and to take afterwards by such limitation, as if it were then actually born. It takes land by descent, though in that case the presumptive heir may enter and receive the profits

* Lecture iii. pp. 68, 69, present volume.

for his own use till the birth of the child, which seems to be the only interest it loses by its situation. These privileges date from the moment of conception: there are others, chiefly having reference to the protection extended to the infant against the infliction of injuries, (hereafter to be noticed) which commence at the time of quickening. The subsequent birth of the child has in all such cases much influence in modifying the nature of the crime. If the child be born alive, and afterwards die in consequence of injuries alleged to have been committed on it *in utero*, it is murder: it is, however, sometimes, in respect to the charge of infanticide, of great consequence to be able to prove that the child was immature, or not likely to have lived, when a person is charged with having caused its death.

Viability.—In France, both for civil and criminal purposes, it is absolutely necessary not only to determine whether a child has been live born, but whether it has also had a capacity for continuing to live. This is what is called its *viabilité*; and an infant is pronounced *viable* (from the Latin *via*), when it is considered capable of proceeding on the journey of life under ordinary circumstances. According to the *Code civil*, concerning inheritances and legacies, the child which is not born viable is placed in the same category as if it had not been begotten. Also, with reference to legitimacy, if a child, born within 180 days after marriage, be declared viable, it may be disclaimed by the husband, provided he was not cognizant of his wife's pregnancy at the time of marriage, nor assisted in registering the infant's birth.

The French law does not define viability: the determination of the fact is therefore left dependent on medical evidence. But it is curious that the French medical jurists are by no means agreed as to what should, or should not, constitute this condition of the new-born child. The definitions they give us are sufficiently vague, and even the latest and most practical of their writers, M. Devergie, after stating the several forms of expression in which the term is defined by Foderé, Capuron, Marc, Orfila, Velpeau, and others, cannot be more explicit than this, that viability denotes "the aptitude for extra-uterine life, characterized by the maturity of the infant, the good conformation of the principal organs of the economy, and the healthy state of those organs at the epoch of birth." Now here are three conditions on which viability is made to depend, each of them affording ample room for discussion. Nor is this all: some of the said jurists hold that the question of viability can only be raised in the

case of children that have died; Capuron, for instance, says that as long as the infant lives, it is seized and possessed of its property beyond the possibility of dispute; but that in case of its death, it may become a question whether it was viable or not, in order to determine whether it was capable of transmitting its succession. Others are of a different opinion; yet it appears strange that there should be any mistake in the matter, when the law seems so plainly to indicate that a *living* child may be declared viable or not, not only, as we have seen, in reference to legitimacy, but the succession to property; for a presumptive heir may enter and raise the question of viability while the infant is still living. There may seem, however, one excuse for the view taken of the subject by M. Capuron—namely, that practically speaking, the fact of non-viability can be rarely determined (however viability may) during the life of the infant; and perhaps it would be in any case as unsafe to pronounce a living child to be not viable, as to decide that a wound is absolutely mortal, the individual who received it being still alive, with all those chances of recovery which nature sometimes so benignantly provides, even in the most desperate cases. But to return to the question of maturity.

Instances of early maturity.—Although it is only the infant produced at the ninth month of intra-uterine life that can be considered completely mature, instances are numerous of children born at earlier periods being *sufficiently* mature to run the ordinary course of human existence. The old writers supply us with some very remarkable cases, which ought not to be overlooked, as it is by the weight of facts, and not by preconceived theory, that the question is to be decided. We have Avicenna, Schenck, Spigelius, Valisneri, Ammanus, Diemerbroeck, and others, stating examples of children having lived to adult age, and even to the ordinary limits of human life, though born only five months after conception. Fortunio Liceti, according to Capuron, was born at four months and a half—at five months, according to Kühnholz—yet lived to the age of 79. His father, says Mahon, did not despair of preserving him, though, when born, he was no longer than one's hand; he put him beside the fire (into an oven, as some say), and there kept him in a degree of temperature like that which favours the artificial hatching of eggs. Belloc mentions his having seen a female infant, born about the sixth month, which was only a foot long, and looked like a little skinned rabbit; yet she was carefully fed, and lived to woman's estate. Marshal

Ribellier was recognized as viable by the parliament of Paris, although born only at five months. Dr. Montgomery, of Dublin, states that the earliest cases he has met with were a child born alive at the end of five months, but which only lived a few minutes; and another born at five months and a half, which lived only four hours.

A curious case became the subject of discussion in Scotland not long since. It was a case of early birth, which, coupled with the state of the child, involved matter for scandal among the maliciously disposed. A clergyman had been married to his lady only five months and twenty one days, when he became the father of an infant—feeble, indeed, and not three pounds in weight—but which by great care was kept alive. It survived birth for several weeks, and may be still living, for aught I know; but its mature appearance was unfortunate for the good repute of the parents: a *fama clamosa* was raised, and various presbytery meetings were held, to inquire and determine how far the clergyman was liable to the charge of having infringed the rules of morality. The character of the parties was luckily good, and there had been nothing like concealment practised—their intended marriage had been approved for months previous to its celebration, and there was nothing to prevent its taking place. When the child was born there was no preparation for it—all were taken by surprise, and nobody expected the infant to live. Under these circumstances, and chiefly moved by the medical certificates produced in evidence, the presbytery decided in favour of the clergyman.

The medical evidence adduced in this case was interesting. Dr. Hamilton, of Edinburgh, was consulted—he could not go to see the child, but sent a statement of his opinion relative to such early births. He said that his own experience was opposed to the probability of a child born in the sixth month surviving, he referred, however, to two cases where children had lived under similar circumstances of premature birth. One of these occurred in 1710, when the wife of a clergyman was delivered of a living child within five lunar months after marriage, and the celebrated Dr. Pitcairn, and two other eminent practitioners, gave it as their opinion that it had been procreated after the marriage of the parents. The other case occurred in 1815, when a married woman gave birth to a living child nineteen weeks after conception, and it lived a year and a half. Beside this opinion of Dr. Hamilton, there was also given that of Dr. Thatcher and

Dr. Reid, who saw the child in question, and examined minutely into all the circumstances connected with its birth: these gentlemen certified that it was quite possible that the infant was begotten after the marriage*.

The opinion of Dr. William Hunter, in answer to an interrogatory which was once put to him on this subject, is worth quoting. "A child may be born *alive* at any time after three months; but we see none born with powers of living to manhood, or of being reared, before seven calendar months, or near that time."

It is evident from all this, that the fact of maturity or immaturity cannot be determined by the mere circumstance of the infant being born before or after a certain time, but that we must be guided in our decision by the physical characters which we find developed. Children at seven months are often very incompletely mature, although it is an age perfectly consistent with viability, there are also numerous instances of children born at this period, well prepared for the business of life. Professor Chaussier was a seven months' child, George the Third, the most long-lived, and perhaps the most prolific of our kings, was born at seven months, complete; and M. Kunhollz mentions his own wife, the mother of nineteen children, as having come into the world at the same early period.

Signs of maturity.—But without referring to precedents and examples which may be readily adduced on both sides, our business as medical jurists can only be properly executed, in reference to the question of maturity, by a careful personal inspection of the infant. We must look to its length, and to what point the middle of the length corresponds—we must observe the size of the head, the growth of the hair, the state of the nails, the colour and texture of the skin, the sebaceous deposit on the skin at the time of birth, and the breadth of the fontanelles. In addition to this, we should attend, in the living infant, to the mode in which the principal vital functions are performed,—those, namely, of respiration, circulation, and digestion. The force and manner of its cries, how it sucks—whether continuously, indicating that respiration through the nostrils is free, or at short intervals, showing that there is a necessity to let go the nipple in order to get breath,—all this should be noticed attentively. Again, from the colour of the skin, the state of the umbilical cord, and the pulse, we may infer the strength of the heart's action. And finally, we can form

* MEDICAL GAZETTE, vol. xvii. p. 52.

a further judgment of the infant's powers from the appearance of the meconium or first faecal matter.

Should there be an opportunity of pursuing the inquiry after the death of the infant, the proofs would, of course, be more tangible—especially those respecting the respiratory functions; for it may then be freely observed and tested how much of the lungs have admitted air, and whether any part of them be diseased. But of such tests there will be a better occasion to speak when we come to treat of infanticide.

Natural and Monstrous Births.

In reference to the shape and structure of the infant at birth, a question may arise, consistently with the actual state of our common law, whether it is human or monstrous.

Legal distinctions.—Our law recognizes monsters; such beings, as the possible issue of human parents, are mentioned in explicit terms. "A monster," we find it stated in Coke upon Littleton, "which hath not the shape of mankind, cannot be heir, or inherit any land, albeit it be brought forth within marriage; but although he hath deformity in any part of his body, yet if he hath human shape he may be heir. *Hi qui contra formam humani generis converso more procreantur, ut si mulier monstrosus vel prodigiosus enixa, inter liberos non computentur.*" Some further limitations of the term are then added—namely, that those to whom nature has given more or less parts than usual, are to be reckoned among the children,—but the increase or diminution is not to be excessive: six fingers or four only on each hand do not disqualify; nor if nature has disabled any members, or distorted them, does this constitute monstrosity*.

Such is the account of monsters given us by the old legal authorities. The merest tyro in physiology at the present day could point out its imperfections, yet it is the law—the law as expounded by the great luminary Lord Coke, and from which no judge would venture to depart without grave circumspection. There can be no question however, but that there is much room for exercising a discretion on the subject, should a case involving monstrosity arise in the courts; and nothing is more likely. It may be raised in a question of tenancy by the courtesy: the right of the tenant rests on the fact of his child having been born alive; but if his opponents can only prove that the said child had not *human shape*, his claim is null.

If a child hath not the shape of man-

kind, he cannot be heir; but if he hath deformity only, he may inherit. This is in fact the substance of what the law says: but what room is there not in these few words for dispute and litigation! Where does deformity end, and monstrosity begin? Besides, there are various unquestionable monstrosities for which the law makes no provision. "You will ask," says Mr. Amos, "how does the law provide for the case of the Siamese youths, their rights in regard to third parties and to each other?—and how for a person whose face may be inhuman, but may possess reason—say the case, real or supposed, of the pig-faced lady? and probably, medical men may put a number of other instances;—I answer, that the law says nothing more than what I have just read; and that, therefore, if a case of monstrous birth should be brought before the courts, the courts will seek for all the medical information that can be obtained, and will legislate for the particular occasion; only they will not call it legislation, but will pretend to found their decision upon Lord Coke's definition; which definition, by the way, is borrowed from Bracton, who borrowed it from the civil law."

Classification of monsters.—The subject of monsters is one of great interest to physiologists, as it throws much light on the operations of nature in the exercise of her formative energy. For the medical jurist also, monstrous births are occasionally possessed of no small interest, inasmuch as the result of certain civil and criminal proceedings may depend on the evidence which he is enabled to give of their actual state—particularly as to whether they are live or still, in reference to questions of tenancy, or charges of infanticide.

Buffon, M. Geoffroy de St. Hilaire, and others, have formed plans for grouping together the several classes, according to those points of analogy which seem best suited to ground a scientific arrangement. But M. Breschet appears to have been the most successful in the simple but comprehensive scheme which he has struck out. His plan, indeed, seems most practical yet devised, and for that reason is eminently entitled to the attention of the medical jurist. Orfila and Devergie both adopt it, and I give it here nearly in the form in which it has been modified by the latter.

The circumstances connected with each state in reference to viability or non-viability, it will be observed, are subjoined in a separate column, so that at one view we have a collection of all known monstrosities, with the consequences in respect to the compatibility or incompatibility of extra-uterine life annexed to each.

* Coke Littleton, vii. 8. 29 b.

Order I. INNETOUS genèses).	Genus 1. Agenesia ..	Acephalia.....	Not viable.
		Anencephalia.	Some have lived 20 days.
		Congenital dropsy.—1. Of the ventricles of the brain, with deficiency of some of its parts.	Death before or at birth.
		2. Of the same ventricles, but with complete development of the organ...	Life more or less.
		3. Of the exterior of the brain fully developed.....	Viable.
		Aprosopia.	Not viable.
		Ateloprosopia.	Not viable.
		Absence.—1. Of the eyes, eyelids, or iris.	Viable.
		Of the mouth.	Not viable.
		— lips, tongue, outer ear.	Viable.
	Genus 2. Diestenasia	2. Of the epiglottis, penis, scrotum, testicles, vesiculæ seminales, uterus, vagina, some of the ribs, some of the vertebræ, part of a member, hand, the bladder	Viable.
		3. Esophagus, stomach, liver, heart or lungs	Not viable.
		Septum between the ventricles or auricles of the heart—the diaphragm	Viable.
		Fissures on the mesian line—of cranium, with large encephalocoele.	Not viable.
		— encephalocoele—less voluminous.	Viable.
		Spina bifida, with hydrorachis in the upper part of the spinal column.	Life for a few days.
		— lower down.....	Life some months or a year or two.
		Fissures of the lips, jaw-bone, tongue, palate, bladder, penis, urethra, womb, vagina.	Viable.
		Division of the mesian line of the abdomen, with considerable hernia of the viscera.	Not viable.
		Exomphalia, with abdominal or thoracic hernia.	Not viable.
	Genus 3. Atresia	Both the preceeding, in a less exaggerated form.	Viable.
		Ecstrophia	Viable.
		Imperforations of the urethra, vagina, uterus, mouth, anus, eyelids, membrana pupillaris.	Viable.
		— of the œsophagus and intestines.....	Not viable.
		Genus 4. Symphysis	
		Fusion of the eyes—monopsia.	Not viable.
		— of other parts of the body.	Viable.
		Giants.	Viable.
		Persons with supernumerary organs. ..	Viable.
		Fused, or united by some parts of the body.....	Not viable.
Order II. MERGENE- OUS	Genus 1. Fusion	United, with fusion of parts.	Not viable.
		United in the upper parts, and separated in the lower.	Not viable.
		United below, and separated above.....	Not viable.
		Genus 2. Penetration	
		One foetus containing another, partly or wholly	Not viable.
		Extra uterine foetus; or more than three foetuses at a birth.	Viable.
		Albinos and chacrelats	Viable.
		Foetus with displacement of organs, all, except—displacement (ectopia) of the heart, thoracic, with fissure of the sternum, and hernia of the heart	Viable.
		— displacement of the heart, and	Not viable.
		—	Not viable.
Order III. LOGENE- OUS	Genus 1. Fusion	United, with fusion of parts.	Not viable.
		United in the upper parts, and separated in the lower.	Not viable.
		United below, and separated above.....	Not viable.
		Genus 2. Penetration	
		One foetus containing another, partly or wholly	Not viable.
		Extra uterine foetus; or more than three foetuses at a birth.	Viable.
		Albinos and chacrelats	Viable.
		Foetus with displacement of organs, all, except—displacement (ectopia) of the heart, thoracic, with fissure of the sternum, and hernia of the heart	Viable.
		— displacement of the heart, and	Not viable.
		—	Not viable.
Order IV. TEROGENE- OUS	Genus 1. Fusion	United, with fusion of parts.	Not viable.
		United in the upper parts, and separated in the lower.	Not viable.
		United below, and separated above.....	Not viable.
		Genus 2. Penetration	
		One foetus containing another, partly or wholly	Not viable.
		Extra uterine foetus; or more than three foetuses at a birth.	Viable.
		Albinos and chacrelats	Viable.
		Foetus with displacement of organs, all, except—displacement (ectopia) of the heart, thoracic, with fissure of the sternum, and hernia of the heart	Viable.
		— displacement of the heart, and	Not viable.
		—	Not viable.

Cursory Remarks.

Some miscellaneous observations may be made on certain parts of the table. And, first, of the genus *AGENESIA*, or deficiency of growth.

Acephalous, or headless monsters.—These constitute a large proportion of the monstrous births usually met with; they are very common in twin cases. Sometimes not only the head is wanting, but the neck; the arms, also, are occasionally deficient, and likewise the chest, the abdomen and legs remaining. In such cases all those organs which ordinarily receive their nerves from the parts that are absent, are themselves deficient. No species of monstrosity so completely excludes the idea of viability.

Brainless, or anencephalous.—The brain may be wanting, while there may, or may not, be a cranium present. A part of the face is commonly also wanting in such cases. When the face is involved in the monstrosity, one or both the eyes are usually deficient, or they are displaced; the nose is altered, &c. Anencephalous monsters scarcely ever live beyond the second day: in general they die in three or four hours; but there are instances of their having survived for twenty days. This must depend upon the portion of the spinal column which is present or absent.

Aprosopia and Ateloprosopia.—Absence, and imperfection of the face, (implied by these terms,) are always accompanied by a very marked deficiency of brain, accounting for the non-viability which attends those conditions.

Absence of mouth, &c.—The absence of various organs, such as the mouth, eyes, stomach, œsophagus, heart, &c., as enumerated in the table, is traceable to some primary defect in the development of the nervous system connected with those organs. The fact of viability or non-viability will depend on the question whether the organs wanting be essential for extra-uterine life.

In the genus *Diestenasia*, (implying separation or un-union) we find *spina bifida*, or dropsy of the vertebral column, mentioned as constituting a monstrosity. The chances of viability depend entirely on the extent of the disease, and the parts which are involved. Sometimes it is found to occupy the whole length of the column, at other times it is limited to a portion of it. Now when it occurs only in the lower portion, as the lumbar region, it does not necessarily compromise life.

Hernia.—Congenital hernias resulting from disunion in the median line sometimes involve not only the viscera of the abdomen and thorax, but, as Beclard has

observed, the face and forehead of the infant may be divided, with protrusion of the contents of the cranium.

In the genus *Atresia*, or imperforation, there is but one monstrosity—imperforation or obliteration of the alimentary canal—which proves fatal to the continuance of independent life.

Monopsia.—One-eyed monstrosity is the only species of *symphysis* (or deficient development with fusion) which compromises viability. It is, however, capable of degrees, and the consequences must depend on the extent to which an imperfection of the brain is involved.

The *HYPERGENETOUS*, or *overgrown* monsters, include the well-known species of giants, and individuals possessed of supernumerary parts. Many remarkable examples are on record, and instances both human and animal are frequently exhibited in public.

Under the *DIPLOGENETOUS* order, there are many curious examples to be classed—such as Helen and Judith, the Hungarian sisters, who lived to the age of 21, joined or *fused* together at the lower part of their bodies, and having but one anus and one pudendum between them: the Siamese twins, also, who must now be about 26 years of age, and whose peculiar union by a fleshy and membranous band from sternum to sternum, with a common umbilicus, has been well examined, and often described, by anatomists. I might also mention, as another instance, the Indian child, an account of which is given in the eightieth volume of the *Philosophical Transactions*, which had two heads, one on the top of the other—the upper one being inverted. But, in truth, the examples of this kind are too numerous to admit of, or to need, further detail.

Parasitical fetuses.—Of that species wherein the duplicature is effected by an original penetration—one germ getting within another—M. Dupuytren has given an account of a most interesting specimen examined by him. A *fœtus* was found in the belly of a lad of 14; it was congenital, and lay comparatively inert until the boy was about thirteen years of age. It then became irritable, and produced inflammation of the surrounding parts; there was a cyst investing it, situated in the transverse mesocolon; this cyst sloughed and opened into the colon, whence pus, with hair and other organic matters, were discharged by stool. The lad at length sunk under it. Dupuytren, on the occasion of recording this example, makes the apposite remark, “that in such cases, so contrary to ordinary experience, while it is the duty of the philosopher, on the one hand, to admit no more than is rigorously proved, he is not, on the other,

rashly to circumscribe the powers of nature."

Suppose a case,—that the subject of a monstrosity like the preceding were a female, might not the contained fetus be mistaken for the consequences of impregnation? And how should the medical jurist distinguish?—The absence of the signs of pregnancy, uterine or extra uterine, would go far to remove doubt; but the chief explanation would be derived from an examination of the embryo itself, when it would doubtless be found to bear evidence of its long sojourn in the place where detected; parts of it, if not all, would exhibit the appearance of being too old and too well developed for a recent conception, especially when the normal state of the uterus and its appendages would be taken into consideration.

I think it unnecessary to occupy your time with an enumeration of those cases in which the penetration is incomplete. The case of the Chinese, A ke, who had a

small parasitical brother protruding from his abdomen, is well known: the model is familiar to all visitors of museums. In the works of Pare, Bartholin, Zacchias, Winslow, and others, similar monstrosities are noticed, but they have no special medico-legal interest.

Of the HETEROGENETOUS monstrosities, examples are sometimes met with which are very striking. In the last two species given in the table—*ectopia* of the heart, with hernia, thoracic or cephalic—the displacement is always fatal, for the heart is merely covered with a thin pellicle, and in other respects exposed.

Transposition of the viscera—Not so when the displacement is within the chest, and not attended with hernia. There are instances of remarkable transpositions of this kind, where the subject has lived for months, years—nay, has attained the ordinary limits of human life.

Here is a representation of the state of the thoracic viscera in a child which lived

FIG. 20.

A, Heart (a bristle passed through the foramen ovale); B, Pericardium; C, Left lung; D, Diaphragm; E, Trachea; F, Esophagus; G, Arch of the aorta; H, Abdominal aorta; I, Artery going to right lung; K, Vain to right lung; L, Vena cava inferior; M, Vena cava superior; N, Pulmonary veins; O, Pulmonary artery; P, Ductus arteriosus, obliterated.

for nearly ten months. It was a sickly infant, however, and suffered much in its respiratory functions, apparently from a deficiency of lung: the right lung was in a very imperfect condition. The abdominal viscera were not displaced; but the liver was enormously large*.

In a paper read last season before the College of Physicians, Dr. Watson gave a full account of all the best authenticated examples of transposition of the viscera on record. No less than thirty-three cases are noticed in this elaborate memoir, which you will find full of interest on referring to it: it is contained in the eighteenth volume of the *MEDICAL GAZETTE*.

Only four of the thirty-three cases were recognized as such during life; this is partly to be accounted for by the fact that there is nothing in the transposed condition necessarily of a morbid nature, nor requiring medical attendance; and partly that in former days the same degree of care, as at present used in exploring the state of the viscera, was never employed. In future, there is reason to believe that examples of this kind will be more frequently detected; and we shall see, in a subsequent lecture, of how much importance it is to ascertain whether in a given case there be transposition or not, as our diagnosis of wounds must be materially affected by the circumstance.

It was attempted a few years since to raise a theory respecting the moral character of persons thus conformed. It was observed that in a few cases transposition of the viscera was met with in the bodies of criminals anatomised after death, and the conclusion was hastily drawn, that depravity of mind was essentially connected with this cross condition of the body. But if Smithers, who was executed in 1832, for attempting to set fire to his house, was found to have this configuration, and if one or two other malefactors were similarly situated, this was far from being a warrant to justify a general conclusion. On the contrary, it so happens that as in most of the well-observed instances on record, there was no change ascertained in the bodily functions, so neither was there in the moral endowments: if any, the balance inclines to the side of goodness: some of the individuals were remarkable for a steady, upright, and benevolent disposition.

I cannot conclude more appropriately than by quoting what Dr. Watson says on the subject:—"More than one of the subjects of this change happen to have been notorious malefactors, and to have ended their lives upon the scaffold; and hence seems to have arisen the fantastical speculation, that as in them the mechanism of the body was crossly modelled, so, by some

sinister and mysterious sympathy, the mental constitution also may have been warped and perverted, and the physical prodigy have been necessarily combined with moral deformity.

"If a notion so preposterous could merit a serious refutation, it might be found in the fact that many of the persons similarly fashioned were but little remarkable in their lives, either for good or evil; while one of them, at least, as we learn from the interesting statement of Sir Astley Cooper, was distinguished for active benevolence and kindness of heart, and passed through a long life in uncommon freedom from the vices most incident to her social station*."

CLINICAL LECTURES,

DELIVERED AT THE

MEATH HOSPITAL AND COUNTY
OF DUBLIN INFIRMARY,

During the Session 1836-7.

By PROFESSOR GRAVES.

LECTURE III.

Erysipelas in an Epidemic form—Symmetrical spread of Erysipelas on the Body—Maculated Fever, and Irish Typhus—Dr. Lombard's Remarks—Improved Treatment of Fever—Choice of a proper Nurse and Assistants—Air of the Sick Chamber—Necessity of attending to Diet and Nourishment.

I SHALL now resume the subject of erysipelas, which I alluded to in a cursory manner at our last meeting. You will recollect I mentioned that we had a kind of epidemic erysipelas in our fever wards during the months of August, September, and October; this has now almost disappeared, for we have had but one case during the present month. The disease generally attacked the head, commencing in the scalp, or about the nose and cheeks; but in some cases it appeared first on the nape of the neck, particularly in those patients who had been blistered in that situation during the course of fever. The fever which now prevails seldom abates in less than fourteen or seventeen days; and it was generally about the termination of the febrile excitement, and while convalescence was going on, that the erysipelas appeared. Usually, on the fourth or fifth day of convalescence, a change was observed in the patient, and the erysipelatous attack commenced, being ushered in by a feeling of weakness and uneasiness.

* *MEDICAL GAZETTE*, vol. xviii. p. 660.

* *MEDICAL GAZETTE*, vol. xviii. p. 412.

an indistinct rigor, followed by quick pulse, headache, some increase of thirst, and in most cases by a marked change in the tongue, which became dry and parched.

The inflammation was of a superficial character, expending itself almost exclusively on the external surface of the corium, and not affecting to any extent the cutaneous cellular tissue.

You are aware that erysipelas becomes obstinate, complicated, and dangerous, in proportion as the inflammation spreads inwardly. In such cases its characters are more distinctly marked, and it makes a near approach to a very formidable disease—diffuse inflammation of the cellular substance. The affection of which I am now speaking was generally simple, and in most cases limited to the superficial apparatus of the corium. It was characterized

by the ordinary phenomena of true erysipelas, namely, redness, heat, a burning sensation, and slight elevation of the affected parts. There was seldom any remarkable degree of œdema, except in some cases where it attacked the eyelids; and I had no instance of abscesses forming under the skin. It was attended with a considerable degree of constitutional disturbance, and the fever generally continued for four or five days. On looking over the cases of this affection, which have been recorded by the gentlemen who had charge of the patients, I find that in most instances the fever terminated on the sixth day. In many cases a peculiarity was observed, to which I have alluded on a former occasion, namely, the spread of the erysipelatous redness in a perfectly symmetrical manner. I believe I was the first to direct attention to the fact, that when erysipelas commences at any point

on the mesial line of the body, it is very apt to spread in a symmetrical manner. Thus, in the present instance, the inflammation commenced in the majority of cases about the nose, and then extended in a perfectly symmetrical manner over the forehead and down the neck; or when it appeared first on the nape of the neck, it travelled down between the shoulders with a very remarkable symmetry of extent and outline. Sometimes this precise correspondence did not exist; but I can assert that in more than two-thirds of the cases it was extremely well marked. It appears, then, that this occurrence is not very rare as my friend Dr. Johnson supposes. When I first noticed the fact of the occasionally symmetrical spread of erysipelas, he said it was an observation of very little importance, and that it was to be looked upon as a matter of mere curiosity, a phenomenon which a man would not see twice in the course of his life. I have, however, shewn it to many of the

students half a dozen times during the last two months.

The treatment of this affection, which was abundantly simple, and the same in every instance, was entirely regulated by the circumstances under which the erysipelatous attack occurred. No local treatment was employed, nor was any required. It was not necessary to apply leeches, cold lotions, fomentations, or mercurial ointments. The cutaneous inflammation was not either very extensive or intense; and the constitutions of the patients did not admit of any kind of depletion. The internal treatment was determined on, more from a consideration of the circumstances under which the disease had appeared, than from an accurate analysis of the symptoms, or from any preconceived opinions of the nature of the complaint. In the practice of your profession you will be frequently called upon to treat affections, in which you will have to consider not only the existing symptoms, but also the circumstances under which they have originated; and in many instances you will find that your treatment will be determined more by the latter than the former. Here we had a number of patients labouring under erysipelas, at a period when the system was reduced by fever, and the powers of life at a very low ebb. No one could think of using antiphlogistic or depletory measures under such circumstances. Recollecting that our patients had just emerged from a dangerous disease, we adopted a very different mode of treatment; and in all cases, except where the patient's strength was unbroken, the fever high, and the local symptoms of an intense character, we had recourse at once to tonics, narcotics, and stimulants. We first gave an emollient injection, and then administered sulphate of quinine in the form of enema, to the amount of from five to ten grains, blended with mucilage of starch. This was administered twice a day, and the patient was directed to take small quantities of wine and light nourishment.

Many of the pupils at the time were surprised at this mode of treatment. From the dry state of the tongue, the occasional delirium, the restlessness, and the headache present, they were inclined to think that the patients would be injured rather served, by dietetic and medicinal stimulants of this description. I had, however, witnessed cases of a similar description, and had observed the tongue become clean and moist, the skin soft and cool, the thirst, fever, and restlessness subside, and the local symptoms disappear, under the use of wine. In this instance, also, the value of our mode of treatment was borne out by the result; for, with the exception

of a single case, all our patients recovered. In one instance the disease assumed a malignant form, and carried off the patient in a few hours. She was a young girl of apparently vigorous constitution, and who had got tolerably well through a dangerous maculated fever; towards the middle of the fever she had exhibited symptoms of cerebral excitement, for which we deemed it necessary to blister the scalp. At the time when the erysipelatous attack came on, she had been for several days ill, and was in that low state in which the skin has a great tendency to become ecchymosed, and form bad sores. This tendency I have observed in many instances of low fever, and it is a condition which is always pregnant with danger. The occurrence of ecchymosis, excoriation, and superficial gangrene, in such cases, is not so much the result of pressure, as of the general debility, and the impaired condition of the fluids and solids of the body. It was in this state of the system, and with her scalp still suffering under the inflammation produced by the blister, that this poor girl was attacked with erysipelas of the face. Unfortunately, at the time the erysipelas attacked the sound skin of the head, the blistered surface was attacked with gangrene; and two dangerous local affections became thus suddenly conjoined. Under this unfavourable complication her constitution sank with great rapidity, and she died in twenty four hours from the commencement of the attack.

I shall now, in pursuance of my intention, proceed to speak of the treatment of fever. I may observe here, that we are now at a point of time possessing no common interest for the reflection of medical observers. It is now nearly two years since my attention was first arrested by the appearance of maculated fever, of which the first examples were observed in some hospital patients from the neighbourhood of Kingstown. This form of fever has lasted ever since, prevailing universally, as if it had banished all other forms of fever, and being almost the only type noticed in our wards. Within the last four days, however, a change appears to have taken place. Scarcely any cases of maculated fever have been admitted within the last fortnight, and the majority of fever patients at present under treatment are free from the cutaneous eruption so frequently observed during the last two years. The cases which we have recently admitted present no spots, or maculae, and have been termed, perhaps improperly, simple typhoid fever. And here permit me to observe, that it would be very wrong to conclude, from this circumstance, that our recent cases are of a more favourable description than those which preceded them; the disease, it is true, ap-

pears to have lost a character which is always looked upon as bad and unfavourable, but it may be just as dangerous a modification of fever as the eruptive typhus. During the predominance of the latter form, all cases without maculae were in general simple and free from danger; but it is probable that this is not the case at present. There are two cases of this non-maculated typhus in the female ward, which are of an extremely doubtful character, and in which it would be difficult to predict the result. Indeed, were I to make any prognosis, I should say that the chances, if not against them, are at least very fairly balanced.

Now, gentlemen, as it appears we have come to a change, and that we may have to treat a new modification of fever, it behoves us to be extremely vigilant. I invite you to watch and study, with the closest attention, the cases of fever which come before you. Let us, in the first place, endeavour to ascertain whether we have seen the close of one epidemic, and are now at the commencement of another. The number of cases of simple typhoid fever have, you perceive, increased in a very remarkable manner, and the number of cases of eruptive typhus have become remarkably scarce. But there is another and a more important reason why we should study these cases with all due diligence and attention. They may be the first examples of a new epidemic, and every new epidemic, as it has its peculiar characters, so has it its peculiar treatment. We cannot follow the same track which we have pursued for the last two years—we cannot apply our remedies with the confidence of experience—we must now strike into a new path, and for some time our practice must be tentative and experimental. It was only after a good deal of experimental observation that we were able to arrive at a plan of treatment adapted to meet the exigencies of the maculated form of fever: and it is very probable that this new fever may prove at first extremely difficult to manage; and it may be some time before the diminished rate of mortality will show that we have at length discovered its true character, and the remedies best calculated to arrest its progress*.

Let me now direct your attention to some practical points connected with the treatment of the maculated fever which has prevailed for the last two years, and which has spread to a very considerable extent in this city and its environs, attacking alike the upper, middle, and lower

* Since this lecture was delivered, many cases of typhus without maculae have been admitted, but the maculated form of fever still continues very common.

classes of society. It is not my intention to enter into a detailed history of the origin and progress of this fever, its varieties, symptoms, and pathological phenomena; my purpose is to furnish you with a brief but comprehensive outline of its treatment, and of the remedies which have been found most successful in its removal, as well as the most appropriate time and mode of their application. But as many of the students are unacquainted with this form of fever, I shall premise by observing that it is the same fever which has been frequently observed in this country, and of which a full account has been given in the Report published by Dr. Cheyne and Dr. Barker. You will also find a sketch of its principal characters in one of my lectures, published in the 172nd No. of the London Medical and Surgical Journal for May 1835. It is generally insidious in its first attack, and the symptoms are by no means proportioned to the subsequent danger. From the third or fourth to the seventh day, generally about the latter period, an eruption of dark red spots appears on the skin in various parts of the body. Towards the latter stage, this fever is characterized by great nervous derangement, either with or without symptoms of cerebral congestion. It rarely lasts less than fourteen or seventeen days, and very seldom terminates by a well-defined crisis. It has spread extensively through this country, and has been observed at Liverpool, Glasgow, Birmingham, Manchester, Edinburgh, and London. In this country it has been for many years the prevailing type, and, although its spread as an epidemic may have been checked, and its course interrupted, by the occurrence of other diseases, it is always found in this country, and prevails in a distinct form. It may originate spontaneously, or from contagion. From what I have seen of it, I have no doubt of its double origin. I am also inclined to think that it never attacks the same individual more than once, and that when a man has had the true maculated fever, he never gets it again. In this point, as well as in the eruption, it bears a close analogy to the exanthemata. It is so much more common in Ireland than in any other country of Europe, that my friend, Dr. Lombard, of Geneva, calls it the Irish typhus. Whether it be from the moisture of our climate, or from the poverty and wretchedness of the people, I know not; but it is a fact that typhus is more prevalent in this country than in any other European nation. This may be easily seen by comparing the proportion of fever patients treated in the hospitals of the various capital cities, with the number treated in the same way in Dublin. Dr. Lombard

also states, that the British towns which have most intercourse with this country, have more of this fever than those which are more remote, or have less intercourse with us. Thus there is more maculated fever seen in Liverpool and Glasgow, than in Edinburgh, Birmingham, or London. He looks upon it as a fever peculiarly Irish, originating in this country as an endemic, from causes the nature of which are not well understood; and that when it appears in English or Scotch towns, it is the result of contagion imported from Ireland. You will find some very interesting observations on this subject in his papers, published in the 28th number of the Dublin Medical Journal.

In the fever of which I speak, there is nothing which would lead to the conclusion that the disease arose from inflammation. Many persons have regarded fever as produced by inflammatory affections of some organ or system of the body, and have asserted that it is in every instance preceded and accompanied by some form of local inflammation. One class of pathologists have placed the seat of this inflammation in the brain, another and a more numerous class in the digestive system; and all have believed that inflammatory action, whether limited to one or more organs, is the cause of fever. No opinion can be more unfounded, so far as typhus is concerned. Local congestion and inflammations may and do frequently arise in fever, but they are merely super-added to it, and form no part of its essence. I have now witnessed many cases in which fever ran through its course to a fatal termination without any distinct evidence of local inflammation or even congestion; and I have dissected numerous cases of fever in which there was not any appreciable trace of inflammatory action in the organs of the three great cavities.

Having made these general observations, I may observe, in addition, that in the whole range of human maladies there is no disease of such surpassing interest and importance as fever; and I cannot dwell too much on the necessity of your applying most attentively to the study of its pathology and treatment. If you compare the mortality from fever with that resulting from any other disease in this country, you will be struck with the overwhelming fatality of this affection, and will readily admit the inestimable value of a thorough knowledge of its nature and treatment. Recollect, too, that fever is a disease which numbers among its victims persons chiefly in the prime of life, and during the most active and useful stage of existence,—fathers and mothers, persons who are the ornament or the stay and

support of their families, the intellectual, the industrious, the efficient,—those whose lives are most valuable to their friends and to society. This gives an additional interest to the study of fever, and should stimulate you to endeavour to arrive at a correct knowledge of its nature and treatment. And here let me observe, that there is nothing more untrue than the assertion, that the treatment of fever is a matter of indifference. It has been the custom to look upon every plan of treating fever as idle and absurd, and until very lately there were many persons in this country who believed that patients recovered, not from having had the advantage of treatment, but from goodness of constitution or some favourable accident; and it was usual with such persons to appeal to the experience of Dr. Rutty, who, in recording the history of the epidemics of his own time, observes, that the mortality was greatest among those who were best attended to, and that those who were left to God's providence, and got nothing but cold water, recovered. And, indeed, I must admit that the treatment of some of the cases of fever which I witnessed when a student, would seem to justify the quaint and sarcastic observation of Dr. Rutty. At that period, whether it was from bad treatment, or from what has been termed the *nimia diligentia medici*, it is a fact that the maximum of mortality was among the rich, and that those who were most attended to died most speedily. In the epidemics of 1816, 1817, 1818, and 1819, it was found by accurate computation, that the rate of mortality was much higher among the rich than among the poor. This was a startling fact, and a thousand different explanations of it were given at the time; but I am inclined to think that the true explanation was, that the poor did not get so much medicine, and that in them the *vis medicatrix* had more fair play. I could appeal to the practice of those times in proof of this opinion, and as we go along I shall have an opportunity of alluding to this part of the subject again, and contrasting the practice of the present day with that which was generally followed thirty years ago. If you look to Dr. Cheyne and Dr. Barker's Synopsis of the plan of treatment employed by the physicians of those days, you will be prepared, from a mere inspection of it, to admit, that it was at least as hard to escape the physician as the disease. Since that period our practice has greatly improved, and things are much changed; the preponderance of fatal cases is now to be found among the poor, and the mortality among the rich, or those who have proper medical advice from the com-

mencement, is not one-third of that which is found among the indigent, who are generally neglected at the commencement of the disease. I am therefore fully prepared to deny that, in the present state of medical knowledge, our practice is a matter of indifference; on the contrary, there is no disease in which diligent attention and skilful treatment are more frequently successful than in fever, nor is there any affection of equal importance in which our therapeutic means are more efficient and valuable.

Now, when called on to treat a case of fever, there are several things which require your attention. In the first place, you should examine the state of the family arrangements. This is a matter which men are apt to overlook or treat as a matter of indifference, but in my mind it is of no ordinary importance, and should always be attended to. You should never, if possible, undertake the treatment of a case of fever where the friends or relations of the patient supply the place of a regular fever nurse. The mistaken tenderness of relatives, and their want of due firmness, presence of mind, and experience, will frequently counteract your exertions and mar your best efforts. Affection and sorrow cloud the judgment, and hence it is that very few medical men ever undertake the treatment of dangerous illness in the members of their own families. The sympathy which a nurse should have for her patient should be grounded on a general anxiety to serve, and a strict sense of duty, as well as a laudable desire of increasing her own reputation; it is, in fact, a sympathy analogous to that which a physician should have. Again, it will not do to have a nurse who has been usually employed in other diseases; your assistant must be a regular fever nurse, and the man who undertakes the treatment of a long and dangerous case of fever without such an assistant, will often have cause to regret. I could mention to you many cases illustrative of the truth of this assertion. I could tell you, that where I have permitted the continuance of the services of one of the family, or of a common nurse, I have been almost invariably annoyed and disappointed. I now make it a general rule to refuse attending any dangerous and protracted case of fever without a properly qualified nurse.

In the next place, when treating a case of bad typhus, do not think that it will be sufficient to see your patient once a day. But you will say, perhaps, that our hospital patients here do very well, and yet they are visited only once in the twenty-four hours. True,—but then we have experienced nurses to look after them at all hours; we have the valuable sur-

ance of our apothecary, Mr. Parr; we the attendance of the resident pupils, of the gentlemen who take charge of cases. You see, then, that they do depend on a solitary visit. How

has Mr. Parr, the resident pupil, is it necessary to change the treatment ordered at the morning visit? How

have the remedies of which we had given a hint in the morning, been fully and energetically employed before the close of the day; and how often lives been saved by the valuable notions to which I have just alluded? One should attend a case of fever without having proper medical assistants. My

vice, in general, is to visit my fever patients two or three times a day, and when I have a bad or a dangerous case to manage, I always have a competent medical assistant to stay by the patient and to attend every change of his malady. I do

know how they manage this matter elsewhere, but in this city we have so many intelligent students, so many young medical friends, and so many well-educated apothecaries, that we are never at a loss for an assistant. This fact is, I think, a sufficient answer to the objections forwarded by Dr. Johnson, in the last number of the *Medico-Chirurgical Review*.

He says that tartar emetic is a double-edged sword, an agent powerful alike for good or evil, and in the administration of which no ordinary circumspection is required. All this I am willing to admit; there is no remedy capable of producing more mischief when abused, but when properly watched, it is, I am confident, the means of saving many valuable lives.

He says also, that Dr. Graves cannot give that share of attention to his patients which the employment of such a remedy demands. He is quite mistaken on this point. I am never at a loss for a skilful person to remain with the patient, watch the operation of each remedy, and modify or change it according to circumstances. The want of proper assistants may be an objection to the administration of tartar emetic, but this objection does not hold good with respect to liniment.

One or two more observations of a general nature. Some persons have such a current of foul air in cases of fever, that you find all the windows in the house

thrown open, not even excepting those of the patient's bed-chamber, and wherever you turn, you are sure to meet with a current of air. Now this is an unnecessary practice, likely to entail disease on the family, and local inflammation on the patient. The bed-room of a patient labouring under fever should be well aired, without what is termed thorough air,

and it should, if possible, be a quiet back room, away from the street. In the next place, it should be sufficiently large to hold two bedsteads conveniently; and you should order the attendants to have two well aired beds in readiness, from one of which the patient should be changed to the other every twelve or twenty-four hours. You can scarcely have an idea of the comfort this affords to a person in fever. The room can be kept properly ventilated by a fire, and the temperature can be regulated by a thermometer. Some persons are in the habit of constantly sprinkling the room with vinegar, others with the chlorides. I do not know that it is necessary, and I think the use of chlorine is doubtful, if not improper, and may prove injurious to the patient.

Having made these few general observations on the steps to be taken by those who enter on the treatment of typhus, I shall now proceed to speak of diet and medicines. In a disease like fever, which lasts frequently for fourteen, twenty-one, or more days, the consideration of diet and nutriment is a matter of importance, and I am persuaded that this is a point on which much error has prevailed. I am convinced that the starving system has in many instances been carried to a dangerous excess, and that many persons have fallen victims to prolonged abstinence in fever. This was one of the errors which sprung from the doctrines of those who maintained that fever depended on general or topical inflammation. They supposed that fever arose from inflammation, and immediately concluded that to treat it successfully, it was necessary to reduce the system by depletion and low diet, and to keep it at this point during the whole course of the disease. Hence the strict regimen, the *diète absolue*, of the disciples of the physiological school, and of those who looked on inflammation as the essence of fever. The more the symptoms appeared indicative of inflammatory action, the more rigorous was the abstinence enforced. If a patient's face was flushed, or his eyes suffused, no matter what the stage of the fever was, they said, "here is inflammation of the brain, and nourishment will exasperate it." If he had red or dry tongue, and abdominal tenderness, they immediately inferred the existence of gastro-enteritis, and all kinds of food, even the lightest, were strictly forbidden. That this proceeds from false notions on the nature of fever is beyond doubt, and I pointed out this fact many years ago, long before the appearance of Piorry's work. Let us in the first place examine the results of protracted abstinence in the healthy state of the system. Take a healthy person and deprive him of food,

and what is the consequence? First, hunger, which, after some time, goes away, and then returns again. After two or three days, the sensation assumes a morbid character, and instead of being a simple feeling of want and a desire for food, it becomes a disordered craving, attended with dragging pain in the stomach, burning thirst, and some time afterwards, epigastric tenderness, fever, and delirium. Here we have the supervention of gastric disease and inflammation of the brain as the results of protracted starvation. Now these are in themselves very singular facts, and well deserving of being held in memory. Read the accounts of those who perished from starvation after the wreck of the Medusa and the Alceste, and you will be struck with the horrible consequences of protracted hunger. You will find that most of the unhappy sufferers were raging maniacs, and exhibited symptoms of violent cerebral irritation. Now, in a patient labouring under the effects of fever and protracted abstinence, whose sensibilities are blunted, and whose functions are deranged, it is not at all improbable that such a person, perhaps also suffering from delirium or stupor, will not call for food, though requiring it, and that if you do not press it on him, and give it as medicine, symptoms like those which arise from starvation in the healthy subject may supervene, and you may have gastro-enteric inflammation, or cerebral disease, as the consequence of protracted abstinence. You may, perhaps, think that it is unnecessary to give food, as the patient appears to have no appetite, and does not care for it. You might as well think of allowing the urine to accumulate in the bladder, because the patient feels no desire to pass it. You are called on to interfere where the sensibility is impaired, and the natural appetites dormant; and you are not to permit your patient to encounter the horrible consequences of inanition, because he does not ask for nutriment. I never do so. After the third or fourth day of fever, I always prescribe mild nourishment, and this is steadily and perseveringly continued through the whole course of the disease.

ON

THE ORGANIC GLOBULE;

A PHYSIOLOGICAL MEMOIR.

By THOS. GORDON HAKE, M.D.

Physician to the Brighton Dispensary, &c.

To direct with enlarged views the philosophic mind through what is useful and instructive in the *living science* of

physiology, and to pass silently over opinions which enfeeble the cause of reason, and make nature appear level with the understandings of the unformed, are the objects which the writer proposes to himself to accomplish. There is truth enough to swell the pride of volumes in the functions and disordered manifestations of the living body; and of these so many remain unanalysed, that the task which is undertaken, of pointing out the way to a more intelligible system of physiology, if in any measure successful, cannot be unattended with good. Facts are numerous, but a legitimate application of their value is rare in physiological inquiries.

It is the character, therefore, of hypotheses, but not hypothesis itself, which merits disrespect. For physiology is the most metaphysical science throughout the range of things; more so than intellectual philosophy, since the mental faculties are manifestly allied to highly organized matter; but in the depths of physiology subsists an invisible world: causes are hidden altogether; effects consequently emerge as objects of wonder rather than research. Those who, with a kind of intellectual creativeness, display a talent of bearing analogies into the arcana of life, which casts a glimmering ray of light on the responsibilities impressed on organization, are not to be blamed as hypothetical. From a suggestion may spring a theory sufficiently important to elicit contradiction; this swells the catalogue of facts; and, finally, a master-spirit may appear, to arrange collected materials anew, and to re-arrange until the picture is so like to nature as to be acknowledged and received.

Because the highest order of intelligence is seldom expended on physiology, it does not rank as the first of the sciences. Another*, owing its dignity to the extent of its machinery, the grandeur of its parts, and not to the superior greatness of its laws, has assumed the pre-eminence, and attracted the largest share of talent, although its laws pertain to the substances of which life is formed, even before the building of its fabric has commenced. It is on the ground, then, that the laws of physiology begin where those of the physical sciences terminate, that the lovers of this branch of philosophy take their stand. Those who

* Astronomy.

meet with no impediment in other pursuits enter on this to find the measure of their understanding, and to acknowledge, that there is none other so expressive of nature's great successes.

The difference between an organic and inorganic body, independently of their functions or use, may be found in the nature of their composition, and expressed by what best defines, in contrast, the regular contexture of the one, and the conformation of the other, as respects the disposal of the primitive elements which gives to each its state. The constituents of either may be alike; it is not, therefore, in component parts that the difference is to be discovered; for four elements, named oxygen, hydrogen, nitrogen, and carbon, may constitute animal or brute matter, their proportions being exactly the same. Nor is it to any superadded principle, as the vital, that the difference can be traced; for organic matter retains its form after that principle is destroyed. Two equal portions, for example, of a membrane being separated from a living body, and the one being preserved, while the other is submitted to total decomposition,—fruitless as it would be to mingle the elements again, with a view to restore the organic state, no other known process than the one by which they were organized being competent to recover to them that past form, they still contain within themselves the capacity of being organized, for the very same elements, in the membrane which was not submitted to analysis, remain organic after their life has ceased.

Organized substances, therefore, may be considered as differing from unorganized in their contexture, of which the primordial cause has remained unknown to the most acute observation and steady perception that reasoners can command; and although individual minds, by urging their invincible desire after truth through the effects, may have an occasional and indistinct vision of a formative cause, no impression of that phenomenon has ever been sufficiently vivid to be retained, or to enable the philosopher to describe to others, or to satisfy mankind of his superior knowledge.

Organic matter is resolvable into parts of the same, although less perfect; and these again may be reduced to sub-organic masses; so that, as human skill can succeed thus far, it is probable that the most perfect state of organization is

built up of even hundreds of other states less perfect, and in a mutual state of dependence.

Between these organic elements of the solids, and the organic globule which appears to form the basis of the living body, no intermediate state of matter has yet been found, unless the rudiments of those discovered in the circulating system be brought forward as shadowing forth the more perfect shapes, and affording an easier transport for the mind along the early gradations of animal formation. In this view the fluid elements of organization may take precedence of the solid, the liquid globules of the fixed, although we have no evidence of a less composite state in these former; so that they must be considered as indebted to their greater relative simplicity rather than to that of their constitution, for the intermediate grade they are here allowed to fill.

It is most impressive to contemplate with due profundity the progress made in the elementary laws of matter by means of combination. A simple body alone has no apparent law; placed beside a second they both manifest a quality; and the same process being continued through a series, a body is formed, the organic globule, which not only resembles, but in its highest type forms a part of that which is conscious of its existence.

Although the link between two kingdoms of nature appears broken by the sudden transition from inanimate to organic, the qualities of the first are only concentrated in the second, and rendered capable of intensest action.

The first step, then, made by inanimate bodies towards complete organization is the globule. This body, however, which is no greater than one seventy-five thousandth part of an inch in diameter, is equally inanimate with the elements of which it is shaped. The formative progress which oxygen, hydrogen, &c. have made on attaining the organic globular state, and passing the intermediate grades of composition, is very great; even this cannot be traced: still the globule, when formed, is as inanimate alone as an elementary gas, or any other simple form, and equally inert. If it is allowable to judge of the composition of the globules by that of the tissues which they constitute, the cellular tissue globule is the most simple. It ultimately consists of oxygen

hydrogen, carbon, and azote; proximately of gelatine, and perhaps fibrine and albumen; but each of these substances is composed of the same elements, of which the proportions only differ. Of either, about one-half is car-

bon, while four-fifths of the remainder consist of oxygen and azote in nearly equal parts, hydrogen constituting the rest. This is the analysis of The-
nard :—

	Carbon.	Oxygen.	Hydrogen.	Azote.
Fibrine	53.365	19.865	7.021	19.934
Albumen	52.883	23.872	7.540	15.705
Jelly	48.881	27.207	7.914	16.998

It has been asserted that the globules described above may be resolved, by further microscopic aids, into other globules of much inferior dimensions.

The second globule which may be considered is the muscular tissue globule, a body separated in its nature and composition from the first. Of this molecule it is difficult to trace the constituency, or define its limits, surrounded as it is by so many heterogeneous tissues. Fibrine may be considered its principal component; albumen may perhaps be added; gelatine, extractive matter, osmazome, phosphates of soda, ammonia, and lime, sulphur and potass, muriate, phosphate, and lactate of soda.

As not the globules themselves, but the fibres which they form, have yielded the above analysis, it is a matter of great difficulty to decide which of the substances, or if all, enter into the composition of the organic molecule called muscular, and which into the connecting media. The probable truth is, that such of the above elements as belong to cellular tissue, a connecting medium of muscular fibre, pertain to it alone; while some of the salts, not being discoverable in the blood which circulates in muscle, belong exclusively to its substance; unless the analysis itself, having been carried too far, may have led to a deceptive recombination.

According to observations much to be relied on, the muscular-tissue globule is of the same magnitude as the cellular, and—that which next follows in the order of consideration—the nervous-tissue globule.

Like the other two, the nervous-tissue globule has been found to consist of parts resolvable into parts more simple, and these have been separated until analysis, ranging the grades of highly

combined matter, has reached the simple elements, and expanded all its force.

Vauquelin has supplied the following analysis of nervous tissue.

Water	80
White fatty-matter	4.53
Red fatty-matter70
Albumen	7.00
Osmazome	1.12
Phosphorus	1.50
Acids, salts, and sulphur	5.15

Nervous globules, which these elements give rise to, have been variously described. Although the correct Edwards has compared their size to that of muscular and cellular corpuscles, and convinced himself of their coincidence, and of the unique diameter of every species of nervous globule, it has been asserted on the other hand, that this body in its least degree of development is as much as the four thousandth part of an inch in diameter, and in its greatest the two thousand four hundredth, the median size being the three thousand four hundredth part*.

The nervous-tissue globule thus dividing itself into classes, observation believes that it has ascertained to which the greater corpuscles, and to which the lesser, belong, and has named, from pre-existing reasons, the former medullary, and the latter cineritious.

So much uncertainty existing in regard both to the exact composition and magnitude of the organic globular corpuscle, science would be altogether at a loss for further information on subjects whereon precision is so hopeless, but for one fortunate truth, that principles are chiefly to be desired, and that they are deducible with as much ease from the more coarse, as from the most

* Bauer.

precise experiments. What knowledge of analysis could teach us more than this;—organization is composed of the same elements as the rest of the universe; its high gradations, which present complexities most curious, and compounds so intricately formed that the accompaniment of some extraordinary effect is demanded, are attended with functional powers both wonderful and new; that the elements, when urged by some irresistible agency into extensive and unprecedented union, unable from the vastness of the force used to blend into ordinary forms such as milder causes might induce, and still less incapable of separating each other, obey the omnipotent force, rise above the most complicated forms of ordinary matter, and are established as organic in the beautiful and surprising form of globular corpuscles, the basis of living tissue.

The nervous tissue globule contains its nervous matter in cells of excessive minuteness.

There is an intermediate substance, of a fatty aspect, among the nervous corpuscles. Should this be considered the fatty matter which the analysis of nervous substance yields?

As we ascend in tracing the organization of causes, those which attach to themselves effective powers equivalent to their high natural sources, it may appear surprising that so perfect a regularity should pervade systems, when slight and apparently inevitable deviations from their established harmony would proceed to more alarming derangement, and finally interfere with the continuance of order. This is prevented by the immutability of the inorganic pervading the organic laws. The latter enjoy a derived, the former an original fixity. So perfectly unerring are the laws of elementary matter, that philosophers have even ventured to name them *eternal*. This immutability pervades every state of combination, and is as manifest in each result as in the simple bodies whence higher effects are obtained. Still, though the laws of matter remain immutable, their manifestations vary with their union, and when this is carried to the highest point, the organic, these laws are so strengthened by each other as to appear to superficial observers suspended; whereas they are only so actively poised among themselves, that their united

forces can resist agents which, from a less perfected union, would call into visible existence the simple qualities of the parts pertaining to this now self-defending organization.

Thus the qualities of the organic corpuscle are the united powers of its component elements, arranged under the influence of some agent more potent than any known, or of a series of agents, and amid a vast series also of modifying circumstances; and the meaning of these creative causes can only be ascertained by an incessant and subtle observation of structure, and reflection on the phenomena which are attendant on organization.

ON THE FUNCTIONS OF MECKEL'S GANGLION

AND THE GLOSSO-PHARYNGEAL NERVE.

To the Editor of the Medical Gazette.

SIR,

THE numerous discussions that have been held this some time past respecting the functions of Meckel's ganglion, and the glosso-pharyngeal nerves, and the experiments lately performed by Dr. Alcock, of Dublin*, have induced me to bring forward the opinion which I hold on these subjects; in doing so, I will confine myself as much as possible to the support of my own opinion, without attempting to controvert those of others, as nothing, in my estimation, tends more to impede the progress of scientific research, than too free disquisitions on the opinions of others.

The situation of Meckel's ganglion, its connexion with the fifth pair of nerves, which possess so marked an influence over the organ of vision, the distribution of its branches to the nose and palate, the remarkable course of its chorda-tympani filament, which passing backwards through the vidian canal, enters the hiatus fallopii, communicates with the glosso-pharyngeal nerve, traverses the cavity of the tympanum, and finally, emerging from it through the glaserian fissure, joins, and is lost with the gustatory nerve, are circumstances which have at all times given rise to much discussion respecting the uses of these nerves, especially when it is recollected that the parts to which they

* MED. GAZ. p. 295, present volume.

are distributed are abundantly supplied with nervous influence from other sources, both for the purposes of common and special sensations. What can be their use? It is, in my opinion, to connect the senses of smell, sight, hearing, and taste together,—to be, as it were, the sympathetic nerve of these senses.

That a remarkable sympathy exists between these senses, every day, nay every hour, affords us numerous examples. The sight of the rose, or other fragrant substance, immediately excites in us the desire of smell; we almost involuntarily apply it to the nose. The habitual snuff-taker, on beholding a snuff-box, perceives a remarkable titillation in the nares, which can only be appeased by partaking of his accustomed stimulus. The sight of his favourite dish, and still more so the smell, arouses in the gourmand an urgent desire to gratify his taste with the object of his wishes; he smacks his lips, and already enjoys the banquet in anticipation, whilst the salivary glands pour forth their secretions in increased quantities. The apple suspended from the tree awakens in the youth the recollection of former enjoyments, and he longs to gratify his taste with the distant treasure. A piece of cinnamon taken into the mouth and chewed, whilst the nose is kept tightly closed, tastes like a piece of deal; an onion, under the same circumstances, like an apple. All those facts prove a remarkable sympathy between the senses of sight, smell, and taste: how many more might be adduced? But how do we show the sympathy between these and the sense of hearing? Very simply. The voice of a well-known friend recalls to our recollection his figure, and we desire immediately to behold him. The sound produced by the pouring of his favourite beverage from one vessel to another—nay, even the uncorking of a bottle—excites in the drunkard an ardent thirst, which can be only appeased by indulging in his usual propensity. The grating noise caused by cutting a piece of cork, paring a piece of slate-pencil, &c. awaken in some most unpleasant sensations, and “set the teeth on edge.” How can we account for these varied sympathies but from the distribution of the branches of Meckel's ganglion?—what other use assign to them?

Some may, perhaps, attempt to ex-

plain them through the agency of the general sympathetic system; but why resort to a general when we can prove a direct cause of sympathy? Others may assert, that in some of the lower tribes of animals these sympathies are present to a certain extent, in which Meckel's ganglion does not exist; to these I would reply, that man is the most highly organized of the animal creation, and that in no particular is the perfection of his organization more apparent than in the great, the universal sympathy, which exists between all parts of his structure, and that, what in other animals may be effected through the agency of the general system, requires in him additional structures; and this observation applies to many parts of the human body, which, in this age of comparative anatomy, have been considered in him nearly or altogether useless; because, forsooth, they are absent in, or may be removed from, the brute creation with impunity. These wholesale deductions from the inferior tribes of animals, and their application to the human system, appear to me to possess much absurdity.

Not less complicated is the distribution of the branches of the glosso-pharyngeal nerve. This nerve, immediately after its exit from the cranium, sends off a band to communicate with the chorda-tympani nerve; after this several branches proceed from it to join the seventh, pneumo-gastric, and sympathetic nerves, and pharyngeal plexus; it then distributes filaments to the stylo-pharyngeus muscle, the constrictors of the pharynx, the lingual muscle, and the constrictor isthmi faucium; numerous branches are also derived from it which supply the mucous membrane lining the pharynx and fauces, the tonsil, and neighbouring mucous glands, the mucous membrane covering the root of the tongue and epiglottis, and the glosso-epiglottic folds. What an extraordinary distribution is here! Filaments distributed to muscles, mucous membrane, and glands, and holding an intimate connexion with the neighbouring nerves; and yet a nerve which is simple in its functions, if we may argue from the simplicity of its origin. What is, then, the function performed by the glosso-pharyngeal nerve? I consider that it connects in sympathy the several parts concerned in the act of deglutition,—that it, in fact, produces that sympathetic action of the muscles of the

tongue, larynx, fauces, and pharynx, on which the integrity of that act depends; at the same time endowing the surrounding mucous membrane and glands with a degree of sympathy which contributes to this action. There can be no doubt that this sympathetic action exists; the rapidity with which the act of deglutition is performed, requiring a consent of action and feeling between so many parts, is abundant proof of it; but many more can be brought forward. A foreign body—a feather, a portion of mucus irritating the mucous membrane lining the fauces—produces immediately a convulsive action of the pharyngeal muscles. A portion of food, or any other substance, impacted in the pharynx, causes immediate death by suffocation; and this is produced, not by compression of the larynx, inasmuch as the cricoid cartilage, which forms a complete ring, prevents this taking place, nor by the direct irritation of the muscles of the larynx, the crico-arytenoidei postici (dilators of the rima glottidis) being most immediately affected, but by the spasmodic action of the constrictors of the larynx, which are called into action whilst deglutition is being performed,—an action which continues as long as the foreign body is allowed to remain. But I have said the glosso-pharyngeal nerve communicates with the chorda-tympani nerve. Can we from this explain that convulsive action produced in hydrophobic patients by the sound of water pouring from one vessel to another, or by the sight of this or other fluids? I think so. This theory respecting the use of the glosso-pharyngeal nerve is supported by the experiments performed by Dr. Alcock. He states as follows:—“I have divided both glosso-pharyngeals in several dogs, with the following results: in two of them, each time that either nerve was taken upon a hook, preparatory to its division, a most violent action of the pharyngeal muscles was excited, resembling precisely the pharyngeal effort to reject the matter, which most persons must have experienced, when something nauseous or revolting has got beyond the power of the tongue, and entered the pharynx; and it was so imperative, that the animal struggled to get upon its feet, and was with difficulty restrained. In a third, a similar effect, only less marked in degree, was produced by pulling

upon the nerve with a ligature passed underneath it; and in one of the three the root of the tongue was at the same time depressed, and rendered concave side to side.” “In every instance deglutition was more or less impaired.” “But in those instances in which the nerves were perfectly divided, deglutition was so very much interfered with, as in some cases to be impossible. The animal took and masticated the morsel as usual, and swallowed it from the mouth into the pharynx freely; but then, after repeated and unavailing efforts to get it further, it made equal efforts to get it back again, in which it often experienced so much difficulty, as to become much exhausted, or to seem even in danger of suffocation, before it succeeded.”

If the foregoing opinions be correct, we possess a satisfactory explanation of the uses of the several nerves distributed to the organs of the senses. To some the nerves of the tongue may appear to form an exception to this remark, as it is difficult to decide what is the office of the gustatory nerve: does it endow the tongue with common or special sensation, or both? I consider that it presides over both common and special sensation. That most of the branches of the fifth nerve endow with common sensation the parts which they supply, is generally admitted; that its gustatory branch performs this office cannot be questioned, from the fact that its branches are freely distributed to the surrounding mucous membrane, the gums, &c., which possess common sensation only. That it also presides over the special sense of taste is, I consider, equally evident, from the numerous experiments performed on this subject, the greater part of which tend to establish this position, and from the circumstance that taste is most perfect in that part of the tongue, viz. the anterior portion, in which the nerve is lost. Against this supposition I am aware that it may be stated, that division of the gustatory nerves will not wholly destroy the sense of taste; but such an experiment cannot be conclusive, as, even after the nerve has been divided, a certain portion of the sense may be conveyed through the numerous anastomoses of its branches, unless the trunk of the fifth nerve be divided; and even in this instance the experimenter must take into consideration, in operating on animals, which

can only be the subject of experiment, how much of the apparent remnant of taste may depend on the integrity of the other senses, and particularly on that of smell. I have no doubt that experimenters have often been mistaken from this cause.

Another objection has been brought forward against this theory—as by Mr. Noble and others, namely, that taste has frequently been lost in an individual, whilst the common sensation has not been impaired, and *vice versa*; but how often do we meet with a similar occurrence in other parts of the body, confessedly supplied by one nerve, with two different powers, viz. that of sensation and motion. It frequently happens that one of these is destroyed, whilst the other remains perfect; so may it be in the tongue: either special or common sensation may be destroyed separately, whether resulting from disease at the origin of the nerve, or a disordered state of its ultimate ramifications, which may no doubt be locally affected, is not necessary at present to be determined; nay, the mucous membrane itself may be in so inflamed or otherwise morbid state, as to increase, diminish, or totally destroy, either or both sensations. Thickening of it, an increased deposit of mucus upon its surface, or effusion into the submucous cellular tissue, may produce all those results, without the nerves participating in the disease.

In the preceding observations I have taken but little notice of the opinions of others: allow me to state to those who have lately written on this subject, that it is not from want of respect for them, but solely from the opinion entertained by me, as at first stated, that the cause of scientific research is frequently impeded in its course by too free disquisitions on the opinions of others; and assuredly, if we wish to illumine our path, it is an injudicious plan to commence by extinguishing our neighbour's light.

In conclusion, I hope ere long to offer some further remarks on this subject, supported by experiment and observations on disease. Should Dr. Alcock, or any other individual, in the meantime continue their investigations, I shall be most happy to receive any arguments that may be brought forward, either for or against my opinions. From a partial knowledge of Dr. Alcock, I feel convinced that all his observations

will be conducted with a single eye to the elucidation of truth, and the consequent benefit of the profession.

I remain, sir,
Your obedient servant,
MALCOLM W. HILLER,
Lecturer on Anatomy and Physiology
at the Westminster School of Medicine.

January 5, 1837.

OBSERVATIONS

ON

MR. EVERITT'S REMARKS ON

THE NEW PHARMACOPŒIA

To the Editor of the Medical Gazette.

SIR,

PERMIT me to make a few observations on Mr. Everitt's criticism on the London Pharmacopœia, which appeared in the last number of your journal.

Intending to prove the folly of directing medicines to be prepared on a small scale, because they can be obtained more cheaply on a large one, Mr. Everitt says—"Thus, A is a maker of carbonate of soda from salt; he gets hydrochloric acid at the same time. B is a maker of sulphate of magnesia from bittern; he also gets hydrochloric acid at the same time; and this acid, procured from distilling sulphuric acid with muriate of magnesia, is just as good as that obtained from salt by sulphuric acid, provided care be taken to have it pure." Now it is readily admitted, that provided two portions of hydrochloric acid are equally strong and pure, that they are equally good, but it does not follow that the modes of procuring them are equally eligible; and until bittern can be obtained free from common salt, the sulphate of magnesia procured from it by sulphuric acid must be mixed with sulphate of soda. This case has, I grant, but little to do with the processes of the Pharmacopœia, but it proves that Mr. Everitt is not happy in the selection of his illustrations.

Mr. Everitt afterwards says, "we will now give a few instances illustrative of the *great care with which the work has been executed*; the italics are Mr. Everitt's, and were not required to show that he meant the great want of

care; he then mentions, "*Ammonia liquor* defined 0.960," and proceeds to state that only two fluid ounces of water should be added to one fluid drachm,* (meaning fluid ounce) of the liquor ammonia fortior to reduce its sp. gr. to 0.960.

When Mr. Everitt's correction is corrected, I admit that he is right; and it was originally stated that these proportions should be employed; the error, I believe a misprint of *tribus* for *duabus*; it is one which I presume Mr. Everitt will pardon, for an error somewhat more difficult of commission, he states that "much of the commercial *liq. ammonia* contains chloride of *colchicum*, meaning *calcium*†.

With respect to the present method of preparing liquor ammonia, Mr. Everitt says it was, "perhaps, the worst of those in the old edition;" and he adds that "the alterations are merely to suit the new measures;"—that is, the alterations are no alterations at all. This, however, is a very incorrect representation of the circumstances of the cases. In the late Pharmacopœia, eight ounces of hydrochlorate ammonia, six ounces of lime, and sixty-four fluid ounces of water, were directed to be used to procure twelve fluid ounces of liquor ammonia. To make a liberal allowance, let it be supposed that one-fourth of the water remained diffused through the lime undissolved; we should then have to heat forty-eight fluid ounces of solution to procure twelve fluid ounces of liquor ammonia; whereas, by the present process, the same quantity of solution yields eighteen fluid ounces of product. In this operation, therefore, smaller vessels, less fire and time, are employed, than in the former one.

Mr. Everitt then shows (and I admit the accuracy of his statement, without allowing that of the inference deduced from it), that, in the present process, half the ammonia of the muriate is lost, and he proposes a method by which this is to be remedied: although an experienced person might advantageously employ some modification of this plan, especially if metallic vessels were used, yet I prefer the loss of ammonia to the complication of Mr. Everitt's apparatus, and the danger which is incurred in distilling under pressure with glass ves-

sels. And I assert that it was not from want of care that a process similar to that proposed by Mr. Everitt was rejected; though whether it was from want of judgment, is a subject fully open to discussion.

The advantages which Mr. Everitt represents as to be derived from his process, show, to use his own expression, with what facility an operation may be "*bungled*." Thus, he says, that if liquor ammonia, of specific gravity 0.960 = 10 per cent. ammonia, be wanted, it may be obtained by passing the ammonia liberated from 10 parts of hydrochlorate into 30 parts of water, until they have increased to 35 parts; and then he adds, "that nearly all the ammonia will have passed over." Now, if 35 parts of solution of ammonia, containing 10 per cent. of the alkali, can be obtained from 10 parts of the hydrochlorate, not only has the whole of the ammonia passed over and been condensed, but the salt must have yielded more than it contained; for 35 parts of solution must contain 3.5 parts of ammonia, requiring 11.1 parts of hydrochlorate for their production, instead of only 10.—I am, sir,

Your obedient servant,

R. PHILLIPS,

F.R.S. L. & E., &c.; and Lecturer
on Chemistry at St. Thomas's
Hospital.

Jan. 12. 1837.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abrégé."—D'ALEMBERT.

Observations on the Construction and Use of the Respirator. By JULIUS JEFFREYS. 1836.

THE "respirator," it may be necessary to explain, is an instrument intended to warm the respired air as it passes through it, so as to prevent the injurious consequences to the lungs of breathing too cold an atmosphere. It must be obvious that the low temperature of the air during a great portion of the season in this country is one of the most fertile causes of pulmonary complaints; and that any contrivance by which persons might have the benefit of fresh air and bodily exercise without the risk arising

* So in the Lancet.

† So in the Lancet.

from cold, is a great desideratum. It appears to us that this purpose is in great measure attainable by means of the instrument described in the pamphlet before us. The principle consists in interposing between the lungs and external atmosphere at the mouth, (or at the mouth and nose jointly), a little apparatus, having metallic gauze so arranged that the air must pass through several folds of it, with minute distances intervening. The heat of the breath is abstracted on expiration, and retained by the apparatus as the air passes out, and is as readily yielded back to that which enters on inspiration; so that before the air reaches the lungs, even on a very cold day, it has already attained an agreeable temperature. The impression which the first description of such an apparatus communicates is, that it must be productive of a sense of closeness and confinement — impeding the respiration, interfering with the voice, and being productive of disagreeable moisture, — in fact, something like breathing through a piece of muslin.

The number of persons who may be seen on a cold day with their handkerchiefs at their mouths, sufficiently shows that some such contrivance as the "respirator" would be very acceptable to them. Now all the advantages they could desire, are professedly afforded by this little instrument. It is an ingenious, clever thing, and so far as we can judge, the principle appears to us excellently suited to its purpose. Two circumstances appear essential to the perfection of the instrument — that it should be sufficient to arrest the heat, and yet not calculated to impede the breathing. Both objects seem to be amply provided for in the "respirator" of Mr. Jeffreys: the wires nearest the mouth are one three hundredth part of an inch thick, and the same distance apart from each other; there are from eight to twenty layers of wire, and those most external are attenuated till they are no more than one six hundredth part of an inch in thickness. The following short extract will perhaps give a better idea of the principle:—

"Since the temperature of any one substance must be lower than that of any other before it can receive heat from the latter by conduction, it is plain that

a single layer of metal could only take a part of the heat from the breath; even if the contact were of longer duration than it is, the breath would lose no heat after it had raised the metal up to its own temperature. In order to extract more heat from the breath, it must be carried through another layer of metal, which, being much colder than itself, can abstract heat from it. As the breath and this second layer approach towards the same temperature, this second layer will not be able to abstract more heat from the breath. It must, therefore, pass through a third still cooler layer, and, for the same reason, through several. In practice, six or eight will not prove too many; and in the coldest weather double that number may be employed. In this series of laminæ, each is warmer than the one in front of it, from the exterior one, which is nearly of the temperature of the atmosphere, to the innermost one, which is perhaps within ten or fifteen degrees of the temperature of the breath. These laminæ would not remain one instant of time at so different states as to heat, if they were placed in contact with each other. In order to preserve the progressive difference in their stocks of heat, they must be kept apart; and it will be found, that during the short period of one respiration, a very small separation will suffice for the purpose. An interval for each of one-fortieth of an inch, including the metal, is more than enough; six or eight layers may therefore lie in one-eighth of an inch. These layers having been warmed during an act of expiration, and being each warmer and warmer as they lie nearer the mouth, are enabled to give heat in the most advantageous manner to the fresh air entering from without, which takes up a parcel of heat in traversing each; since, although it grows more and more warm, it is sure to find every layer it comes to warmer than itself, which is, of course, a relative condition necessary for the communication of heat to the air."

The instrument costs two guineas (we believe), and we recommend it to the attention of those who have delicate lungs. It may be fastened without difficulty by means of a ribband round the head, and would not be more remarkable than spectacles must have appeared when first introduced.

A Practical Treatise on the Diseases of the Skin, arranged with a view to their Constitutional Causes and Local Characters, including the substance of the Essay to which the Royal College of Surgeons awarded the Jacksonian Prize, and all such valuable Facts as have been recorded by Continental Authors on these subjects, to the present time. By SAMUEL PLUMBE, &c. &c. Fourth Edition, revised, corrected, considerably enlarged, and with additional engravings. Sherwood. 1837.

A MEDICAL work must have some merit to come to a fourth edition, and this proof Mr. Plumbe's Treatise on the Skin now possesses—to say nothing of numerous other evidences of the same fact. We observe several methods to be adopted in works on the skin—one set of writers trust entirely to description, without plates (as Mr. Green); others depend, if not exclusively, at least principally, on plates (as Alibert); and yet others combine both methods—as Willan, Bateman, and Rayer. Mr. Plumbe's book does not exactly belong to any of these; he trusts principally to description, and gives but very few plates—nay, he maintains that good descriptions have great advantages over plates, “unless executed with extraordinary skill and at enormous expense.” Now we cannot quite agree in this opinion, and we find it contradicted by Mr. Plumbe's own plan, which combines plates with description. If our author did not feel the advantage of plates, why did he give any? The simple statement of the case we conceive to be this,—that plates render all such works so dear, that they do not meet with ready purchasers; but no one, we conceive, who has to study diseases of the skin, will admit with Mr. Plumbe, that descriptions in words are not prodigiously aided by a simultaneous appeal to the eye. Neither, certainly, can we admit that the excellent engravings of Willan and Bateman “have sunk into utter inutility,” although their expense renders them less generally accessible than could be desired. Nor do we think the argument of the superiority of verbal description quite a safe one for Mr. Plumbe, because, in this case, we apprehend that the minute, elaborate, and valuable work of Rayer, as translated by Dr. Willis, and containing

1238 closely-printed pages for the sum of £1 8s., must be a better bargain to the purchaser than his volume containing less than one-half that number of pages, and not nearly so closely printed. But then Mr. Plumbe's volume has four very good plates; and here again is a practical contradiction of his own position. In fact, the object of our author's remarks about the relative value of plates and text seems to be pretty much this—to intimate that his volume contains just so much text, and just so many plates, as to occupy the golden medium between the two extremes.

Though we smile at the special pleading on the above points, we by no means wish to speak disparagingly of Mr. Plumbe's book. Quite the reverse; we really think very favourably of it. The present edition contains two additional figures, and has numerous extracts (some of them amounting to ten or twelve successive pages), from the translation of Rayer, &c. We recommend to him to follow the French author in another respect—namely, to accompany his fifth edition (for we doubt not we shall see it at no distant period) with an atlas, on the plan of his fellow-labourer in the same field. At present Rayer's book is, in reference to the quantity of its materials, by far the cheapest: next to it comes the one before us.

Theoretisch-praktisches Handbuch der Chirurgie. (Theoretical and Practical Manual of Surgery.) Herausgegeben von Dr. J. N. Rust. 1830-1836. Berlin und Wien. Schloss.

THE Germans have evidently a much more enlarged idea of the nature of a manual or handbook than we have, when they call by that name a work, like that before us, in seventeen goodly octavo volumes. It is what we should call an encyclopædia of surgery, alphabetically arranged; and so far as we have had an opportunity of examining some of the articles, it is a production worthy of the learned editor and his able collaborateurs. Dr. Rust has written a very considerable number of the articles himself, and seems to have carefully superintended all, so as to give a uniformity and consistency to the whole. A very useful supplement, in a thin octavo, accompanies the work, presenting a systematic view of

the theory and practice of surgery, in the shape of a *catalogue raisonné*, with abundant reference to the contents of the volumes. To the scientific surgeon, familiar with the German language, this publication must be invaluable.

Handwörterbuch der reinen und angewandten Chemie. (Dictionary of Chemistry, pure and applied.) Herausgegeben von Dr. J. LIEBIG und Dr. J. C. POGGENDORFF. Erste und Zweite Lieferungen. Braunschweig, 1837. Schloss.

Handwörterbuch der Praktischen Apothekerkunst. (Dictionary of Practical Pharmacy.) Von W. L. BACHMANN. Nürnberg, 1836.

Of the first of these dictionaries we are inclined to form very sanguine anticipations: the names of the editors are indeed a strong guarantee for its success; but there are as yet only two parts out, and the whole is announced as likely to extend to five volumes. We shall be anxious for its steady and regular appearance until complete. Of the second work, we can only say that it is likely to be useful as a dispensatory; it is to be completed in two volumes.

Aufsätze und Abhandlungen aus dem Gebiete der Medicin, Chirurgie, und Staatsarzneikunde. (Essays and Papers on Medical, Surgical, and Medico-legal subjects.) Von Dr. J. N. RUST, &c. Zweiter Band. Berlin, 1836. Schloss.

WE noticed the first volume of this collection some time ago. The papers now published are of a similar character: they are chiefly surgical; but the appendix contains some of a miscellaneous nature,—particularly an interesting account of hydrophobia. An excellent representation of a dog labouring under rabies appears as a frontispiece.

Handbuch der Medicinischen Klinik. (Manual of Medical Clinic.) Von Dr. M. E. A. NAUMANN, Professor der Med. zu Bonn. Sechster Band. Berlin, 1836. Schloss.

THIS sixth volume of a work much esteemed in Germany, though we believe little known here, is chiefly occupied with remarks on urinary and calculous diseases.

MEDICAL GAZETTE.

Saturday, January 14, 1837.

"Licet omnibus, licet etiam mihi, dignitas Artis Medicæ tueri; potestas modo venandi publicum sit, dicendi periculum non recuso."

CICERO.

THE MYSTERIOUS MEDICO-LEGAL CASE.

LAST week we published Mr. Girwood's account of the examination of the woman's body found in the Edge-ware Road; in the present number we give the examination of the head, for that part has since been found, under very curious circumstances. It is difficult to say exactly how much of the mystery has been cleared up by this fresh discovery: some light, however, has been gained by it. There is a severe contused wound upon the head, apparently inflicted during life; all the other marks of violence were attributable to its having been so long in the canal, tossed about and struck by the boats passing and repassing. The legs have not yet been found, but no pains are spared by the police to come at the "heart of the mystery." In time, we suppose, it will all out, though there is no immediate likelihood of such an occurrence.

Two opinions are prevalent regarding the discovery of the body; either there has been a most deliberate and daring murder committed, or some person or persons have outraged public decency by mutilating and exposing a dead body in a grossly wanton manner. The weight of evidence (so far as evidence has yet been attained) appears to us, we confess, to preponderate in favour of the first opinion, and we shall state briefly some of our reasons.

It seems highly probable, from the appearances noticed in the medico-legal inspection, that the woman did not die of disease—the viscera were

sound, there was no mark of medical treatment—and what seems to indicate that the death was sudden, and occurred unexpectedly, the stomach contained food—a full meal had been recently taken. As long as the head was not forthcoming, there was certainly room to doubt whether there might not be organic disease in that part sufficient to account for death: but the discovery and inspection of the head has left that room no longer; the brain was found firm, and perfectly free from disease.

The head, however, presents something more than negative evidence: there is a lesion on it which was most probably inflicted during life—such a lesion as would be produced by a heavy stunning blow. This is a strong fact; for it not only suggests the manner of death, but the revolting method adopted to make it sure. It is impossible not to imagine that the unfortunate woman was suddenly stunned by a tremendous blow, that stupor ensued, and that the perpetrator lost not a moment in decapitating and truncating his victim. That this was done *immediately* after death, there can be no doubt, from the complete hæmorrhage that ensued: the body was drained of its blood; and what further shows that extraordinary dispatch was used, the draining still continued after the headless trunk was tied up in the sack.

The supposition that the mutilation was effected by some medical person, and the body packed up for anatomical purposes, is met by circumstantial evidence of a strongly presumptive character. The trunk was tied up in a sack, which one can scarcely refuse to believe belonged to some carpenter; the chips and shavings of wood at the seams of the sack, the peculiar cord with which it was fastened—a sort of sash-line—the rags found in it, with marks upon them such as are produced by wiping edge-

tools which have been sharpened,—when in addition to this we consider the dexterous use made of the saw, we cannot fail to be struck with so many circumstances pointing out the perpetrator of the *mutilation* at least (whoever or whatever caused the death) as being a mechanic, such as a carpenter or cabinet maker. The saw is not the instrument which a medical man would use for decapitation. Besides, no medical man, unless we suppose him involved in the guilt of being at least an accomplice, would proceed to mutilate a body, almost ere life was extinct.

But what rational ground is there for supposing that the body was intended for dissection? The occupation of the resurrectionists is wholly gone: subjects for anatomical purposes are procurable with comparative facility; and there is no inducement to secrecy: on the contrary, every dissuasive from it; for a heavy pecuniary penalty attaches to any contraband or unlicensed meddling with the dead. Admitting, however, for a moment, that there was some such contraband dealing in the case, the suspicion of murder is not a whit diminished by the circumstance: whoever deposited the body at the side of the public road, and threw the head into the canal, must have known how the deceased came by her death: that death was recent; the body had never been exhumed—it was still reeking from the mutilations.

Thus, taking a general view of the facts, without entering into minor considerations, which we doubt not would still further strengthen our position, there can, we think, be little difficulty in deciding which of the two prevalent opinions is the more tenable. There may yet, possibly, be some other mode suggested of accounting for the circumstances, but at present we have no idea of any such.

It is now upwards of three weeks since the body was discovered; this is

another fact in the murder scale : if the deceased had died a natural death, is it at all likely that the certainty of such an occurrence would be concealed so long ?

We have hazarded these brief and desultory remarks, because we think the subject is one on which every member of the community ought to bestow some reflection. The object of such reflection is not mere idle speculation ; it may tend to the unveiling of guilt, or the removal of the imputation of crime. Nor can we allow that, in this stage of the inquiry, there is any impropriety in discussing the circumstances of the case. An inquest has been held ; the evidence has been laid before the public ; and the medico-legal reports, in their most authentic form, have been presented to our readers. Why, then, should there be any obstacle to discussion ? The case would be very different if there were an accused party in question—if any particular individual awaited trial for the alleged crime. But at present judicial inquiry is at a standstill ; it is difficult, then, to see how the ends of justice can be better forwarded than by a free canvassing of the facts already ascertained.

We can only recollect one case bearing a resemblance to the present : we allude to the murder of M. Ramus, which occurred at Paris in the year 1832. The head of the victim was found in the Seine, his legs in another part of the river, and the trunk in the sewer of one of the streets. The discovery of the mutilated remains was made within a week after the murder ; for a murder it proved to be : the unfortunate Ramus was first stupefied with brandy and prussic acid, and then immediately cut to pieces. The mutilations were effected with a butcher's knife. In about six weeks after the medico-legal inquiries, the murderer was discovered ; he confessed the manner in which the

crime was committed, and it exactly tallied with what was inferred previously by the medical jurists.

By the way, if the Edgeware Road case had occurred in Paris, we cannot help thinking what a sensation it would have produced in the medico-legal world : how many voluminous reports, and with what formality, would have been drawn up, signed, and attested ! Here there is a perfect contrast in this respect : we have no special practitioners appointed to investigate cases of this kind ; the parochial surgeon of the locality is immediately applied to—in the present instance, fortunately, a very competent and able person to be entrusted with such a task ; his reports and evidence are received as all-sufficient, and justice proceeds in her inquiries without deviating in the least from her ordinary course.

THE INFLUENZA.

THIS epidemic, of the prevalence of which in Scotland the newspapers have recently given us notice, is now at length prevalent in the metropolis, to a very great extent, and in many instances with considerable severity. In addition to the symptoms of catarrh many have giddiness, pain under the sternum, or at the pit of the stomach, oppressive headache, and a frequent but generally a soft pulse. There is often much thirst, and the appetite is for the most part almost entirely gone. In all there is great feeling of languor, and the convalescence is very slow. In some the chest affection is very formidable, being accompanied by inflammation of the wind-pipe and air-passages generally ; in others there is inflammation of the lungs or pleura. Most of the medical men in London have been in full employment for the last week, and some of them are quite overwhelmed with business. By the way,

the "general practitioner" has an immense advantage over the physician in such an epidemic. The latter, who may see, perhaps, five or six, and sometimes even more members of a family, generally gets but his usual *honorarium*, of a guinea, for his visit; the former having to furnish each patient with medicine, lays all under contribution, and thus a visit to one family is as productive to him as to five or six ordinary patients.

THE NEW UNIVERSITY.

LORD BROUGHAM has withdrawn his name from the New University—a fact strongly indicative of his opinion as to the chance of its success.

Dr. Locock's name does not appear in the published version of the charter, although he holds a seat in the *Senatus*: we presume that he has some "friend at court," who procured its omission as an act of kindness.

REPORT

OF AN

EXAMINATION OF THE HEAD OF A FEMALE

FOUND UNDER MYSTERIOUS CIRCUMSTANCES; WITH REMARKS.

By G. F. GIRDWOOD, Esq.

A SEALED parcel, obtained from the superintendent of the police, was opened by Mr. Girdwood, in the presence of Mr. Thornton, the churchwarden, and Mr. Bennett Lucas, Lecturer on Anatomy; Mr. Birtwhistle, Surgeon, Mile End; Mr. Webster, Surgeon, Connaught-Terrace; Mr. Trewick Jones; and Mr. Parrott; the parcel was identified by Mr. Birtwhistle as the one found in the canal, near Mile End.

The head is that of a female, and of a middling size; the skin is fair; the hair is of a brown—a dirty brown colour, with a trace of grey here and there in it, the longest tresses two feet long.

The eye-brows are well marked, and, with the eye-lashes, which are not very

long, are of a dark-brown colour. The eye is grey, with a shade of hazel in it. The frontal sinuses are strongly marked, and extend over the eye to the outer edge of the orbit. The nose is at the upper part flat, and a short way above the point, is depressed; the tip itself has a slight twist to the right side, occasioning the right nostril to be somewhat more dilated than the left. The mouth is middle-sized. The lips large, more especially the upper, and prominent. The front teeth are good; the enamel at the points of all of them is much worn from friction; they were, of course, in life, directly opposed to each other. The chin is small, and round; but its exact shape cannot be well ascertained on account of its mutilated state, and from fracture of the lower jaw, on the left side.

The profile struck all of us as being very much that of the lower order of Irish.

The ears are flat; and there is the mark of pressure on the upper part of the concha; both ears are pierced for the ring; the left ear for that purpose has been pierced a second time, the original hole having apparently given way from being too near the edge of the ear. This circumstance, we are satisfied, has not been recent, the notch being completely skinned over.

The section which has removed the head from the body proceeds across the neck anteriorly through the skin, immediately under the fold formed by the junction of the chin with the neck, as far as the sterno-cleido mastoideus muscle, on each side; it then becomes jagged in appearance, and slants downwards nearly two inches, so that the posterior cut of the neck is exactly on a line with the section of the vertebral column.

On examination, it is found to be the fifth cervical bone that is sawn through, leaving the posterior spinous process. The sterno-cleido-mastoidei muscles are retracted about an inch; the carotid is also somewhat retracted.

The face is very much bruised and wounded; the under-jaw is fractured on the left side, opposite to the second bicuspid, and the coronoid process on the right side is also broken.

One wound only presents an ecchymosed appearance. It is one received on the right eye. Around this organ exists a broad ecchymosis, extending

downwards as far as the end of the nose. The cheek under the eye is puffy. The eye itself is wounded, ruptured, and collapsed, all the humours having escaped.

The wounds that have no ecchymosis around them are, one on the nose on the right side, another over the external commissure of the right eye, another on the right cheek under the zygoma, a large bruised one over the lower jaw on the right side (being evidently the same injury that has fractured the bone), another on the right commissure of the mouth, tearing the cheek through for about half an inch, and a very large wound, in the form of a crescent, on the left cheek, extending from the internal edge of the orbit to about an inch external to the left commissure of the mouth, and under it is another bruised wound, apparently proceeding from the same cause that broke the under jaw on the left side; there is also a wound of the scalp, near the crown of the head, also without effusion around it.

An incision was made through the scalp from ear to ear, and the flaps turned anteriorly and posteriorly. A large ecchymosis presented itself, three inches in diameter, on that part of the periphery of the cranium exactly opposite to the right eye. There is a little coagulated blood under the scalp, and the scalp itself is thickened.

On raising the calvarium, the dura mater was of a natural colour, except opposite to the situation of the bruise just alluded to it was redder, and some bloody serum was effused underneath it. The larger vessels, usually filled with blood on the surface of the brain, were empty. The arachnoid membrane presented a few opaque patches. Sections made throughout the cerebral mass and cerebellum, presented no abnormal peculiarity.

The wound of the right eye had not injured the orbitary plate.

The body, without head and legs, on which an inquest was lately held, was exhumed. The head now under examination was placed with the two cut surfaces of the neck in apposition; they were found in every way exactly to correspond, even to the superficial cut noticed at the inquest as existing on the right side of the neck.

The head and trunk, when placed together in a manner so as to ensure

accuracy, were found to measure in length 33 inches.

The report that has already appeared in the GAZETTE was confined to medical facts, with the exception of some allusion to the appearance of the bag. The child's dress and pieces of rag placed round the body, and the cord that bound it round, were minutely examined. The dress is sufficiently described.

The two pieces of rag were common calico: they were in part dry, in part clotted with coagulum, and wet with serum. In addition, they were stained with something black and greasy: these marks, when rubbed by the finger, so as to make a smooth surface, showed many minute glistening points, like plumbago or the oily side of a razor-strop. Most of them were without any definite shape, but several were straight in one of their edges; and one more especially presented the impression of something whose edge must have been slightly acute — something less than a right angle. The pieces of cord consisted of a bit of common cord, a bit of blue blind-line, and a bit of sash-line, much worn at one end, and particularly on one side of the line.

Referring to my former report, it may be added, that the carunculæ myriformes existed; and that where the spots appeared in the small intestines, there was no corresponding structural derangement on either the mucous or serous surfaces.

An interesting question or two suggest themselves in relation to the body. The fact of the death being sudden, and whilst in health, and shortly after a meal, is already disposed of; how, then, has this person met her death?

The state of the wound of the eye, with the bruise on the occiput correspondent with it, differing from all the other wounds and bruises, by having coagula and ecchymoses upon them, and evidently both produced by the same blow, imply their occurrence before death. This blow was enough to occasion stupor, if not death.

The incision around the neck, the cut through the skin being two inches above the cut that separates the trachea and vertebra, implying thus much retraction of the skin while the operation was going on, suggests the idea that

the decapitation was performed with the head in a depending position, and so, probably, after death.

Another question has occurred;—who has been the agent in this affair?

The bag, the cloths, used evidently to wipe edge-tools after being sharpened—the blind-line, the sash-line, worn exactly in the manner in which the pulley passing it would have worn it—form a group of circumstantial evidence pointing out the *employment* of the individual. His trade, in all probability, was that of a carpenter.

148, Edgeware Road,
Jan. 12, 1836.

DISTURBANCE IN THE BOROUGH.

We cannot suffer the following letter to pass without some remark: what we have to say shall be subjoined.

To the Editor of the Medical Gazette.

SIR,

By the manner in which you have alluded, in your last number, to the late disturbance at St. Thomas's Hospital, you have (perchance unwittingly) raised a prejudice against an accused and unheard party, in a way which is scarcely consistent with the duties of a British journalist.

The discredit of that transaction is made by you to rest solely with the students of Guy's Hospital, for which your only authority must be the *ex parte* statement of their accusers. Their defence is still unknown to you; and as the cause now awaits the decision of a jury, you have not only assumed as correct that which remains to be proved, but have conveyed an impression to your readers to the prejudice of gentlemen who are compelled for the present to lie under an accusation, the proper opportunity for answering which has not yet arrived.

None are more ready than the accused to agree with you in denouncing the disturbance as "a most discreditable affair," and none would have more gladly witnessed its conciliatory termination; but the gravity of the charges publicly made against them, and the manner in which they are urged, have left them no alternative.

As defendants, they court, and will now secure, the fullest scrutiny; and no responsibility will attach itself to them if

the result should be otherwise than their accusers anticipate.

Your remarks upon the unsolicited notice taken of the transaction by another journalist, plausibly as you have proffered them, and your subsequent allusion to the recent outrage at Apothecaries' Hall (which was perpetrated by a pupil of St. George's Hospital), are so obviously irrelevant to the question, that we forbear to allude to them further than to express our astonishment that you, in your editorial capacity, should have associated them under the title of "Recent Disturbance at St. Thomas's Hospital."

As our object is sufficiently explained by this letter, which we trust that you will insert at the earliest opportunity, we will only add the hope that your journal will not be made the vehicle of party communications, which must of necessity be premature, and can effect no useful purpose. The accused and their friends are well content to abide the time when the part which each has acted will be investigated in all its bearings.—We are, sir,

Your obedient servants,
T. WILKINSON KING.
ALEX. TWEEDIE.
CHARLES GASELEE.

Guy's Hospital,
Jan. 9, 1837.

It would be difficult to imagine any confirmation of the justice of the remarks which we made last week, or of the extent to which they were called for, more strong than is afforded by the preceding letter. So far from being anxious to "raise a prejudice," or to speak harshly of the accused parties, we attributed what had passed to "a moment of youthful impetuosity," and expressed our deep regret that some accommodation had not been effected, as the course most accordant with the interests of all. But it is clear that our correspondents are equally indignant at the idea of any portion of blame attaching to the gentlemen of Guy's, and at our presumption in offering them advice.

The assumption that the only authority we can have for our opinion is the *ex parte* evidence of their accusers, is incorrect; we were guided entirely by the statements on both sides, as adduced before the magistrates. Neither have we any where said that the discredit of the transaction rests

"solely with the students of Guy's Hospital;" but we remarked, that the scene which occurred was one of "unwarrantable violence," even although it might have occurred in "the maintenance of a right."

The assertion that our reference to the part taken by the Lancet, and to the affair at Apothecaries' Hall, is "irrelevant," leads us to doubt whether the parties understand the meaning of the expressions they employ. Our object was to caution those concerned against supposing that they were on the right side because the Lancet happened to take up their cause; for, as we observed, to serve his own purposes, "Mr. Wakley endeavours to identify himself with the pupils, even where they may be wrong," and we illustrated this by alluding to the striking fact, that he went so far as to justify the personal assault made on the members of the Court of Examiners—than which, so far from being "irrelevant," we maintain that an example more apposite could not possibly have been adduced.

To the hope that our journal will not be made the vehicle of "party communications," we must answer by reminding our correspondents, that they were themselves the parties who began, and who continue, the publication of *ex parte* statements; and that, to comply with the wish they now express, it would be necessary to exclude their own communications.

The fact is, that so far from having been the vehicle of "party communication," this journal, and this journal alone, has been equally open to the statements from Guy's and St. Thomas's indifferently; nor can a stronger proof of our impartiality be given than the insertion of such a letter as the preceding.

If the letter addressed to us is to be received as indicative of any thing more than the opinion of those who attach their names to it, we can only regret that there should be any who suffer their feelings to be so much excited as to blind their judgment. In a cooler moment they will distinguish between the disinterested and conciliatory advice of a journal (which, how-

ever, will never either flatter or truckle them), and the dishonest artifices of a contemporary, who notoriously takes delight in fostering every dissention, and fanning every spark into blaze. His reporting what was obviously wrong, and his unparalleled insolence towards the officers of St. Thomas's, have done the implicated in this affair infinite mischief; and whatever the result may be with regard to individuals, we have no doubt that a total separation of the hospitals will ensue—to the irreparable injury of both—
ED. GAZ.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, January 10, 1837.

MR. EARLE, PRESIDENT, IN THE CHAIR.

A PAPER, by Dr. Hume Weatherhead, on the subject of Inflammation, was read this evening; but in consequence of its length, there was no time left for discussion. On the motion of Dr. Clendinning, seconded by Dr. Johnson, it was arranged that a discussion of the paper shall take precedence of other business on the next night of meeting.

We are prevented this week, through want of space, from giving an abstract of the paper; but it shall be published in due time for those who wish to canvass its merits.

Mr. Earle, before adjourning the meeting, introduced to the notice of the society the Mouth Respirator, lately invented by Mr. Jeffreys, with a strong testimony in its favour: he also mentioned that the inventor himself was present, and would be happy to explain the principles of his ingenious contrivance.

Mr. Jeffreys then gave an account of the various steps by which he brought the instrument to its present state; but as we have noticed Mr. J.'s pamphlet in another part of this number, it is unnecessary to enter into further particulars here.

WESTMINSTER HOSPITAL.

Malignant Tumor of the Mammary Gland.

DEC. 24th, 1836.—This day Mr. Hale Thomson, the assistant-surgeon, amputated the nipple and a portion of the left mamma of Mary Wayland, a woman about

15 years old. The patient has been married several years, but never had any children, nor ever conceived; and for the last two or three years the menses have become gradually more and more scanty: they still appear regularly.

In the summer of 1834 she was in service; and being employed in washing a dog belonging to her master, the animal, in his efforts of resistance, sprung up and struck his head against her left breast. She experienced considerable pain at the moment; this subsided in a short time, but returned at intervals for three or four months.

After this lapse of time she sought medical advice. Leeches were regularly applied three times a week to the affected part, for a considerable period, and various topical remedies were resorted to, with partial success in alleviating the intermittent pain. About twenty months ago, however, a stillation of a dark fluid, very similar to, if not identical with, venous blood, commenced from the injured nipple. This discharge has continued unremittingly ever since, and has uniformly amounted to several drachms a day. After the regular appearance of this sanguinolent issue, the fits of pain became less frequent and pungent, but a soreness was always perceptible on handling the breast.

She was admitted into this hospital on the 29th day of last November. At this time the soreness of the breast was undiminished, and a hardness of the gland was detected. The morbid secretion still continued. Several palliatives have been used without benefit; and to prevent the disease from assuming a more decidedly malignant character, amputation was determined upon.

The part was excised in the usual manner, by two elliptical horizontal incisions. The cellular tissue was removed clean from the surface of the pectoral muscle. Upon cutting into the tumor, a third only of the mammary gland was found diseased. The lactiferous tubes leading to the morbid portion were enlarged, and their lining membrane apparently injected. The veins proper to the part were grown as large as crow-quills. The condition of the surrounding cellular tissue was materially changed, and, in the opinion of some judges present, possessed some characters not unlike incipient carcinoma. The consistence of the cellular membrane, for some distance indeed round the affected part, was certainly firmer than natural.

Dec. 27th.—The patient has experienced no untoward symptom since the operation, and the wound promises to heal by the first intention.

POISONING WITH ARSENIETTED HYDROGEN GAS.

CASES of poisoning with this substance being rare—not more than one or two, in fact, being on record—the following paragraph, which we transcribe from a Cornish paper, will probably be considered interesting:—"On the 5th inst. (December 1836) Mr. J. E. Bullocke, son of Mr. Bullocke, of Penzance, who has for some time resided with Mr. Beard, chemist, in this town (Falmouth), delivered a lecture on the Gases, at the Mechanics' Institute; and, on the 19th, performed a series of experiments in illustration of that lecture. Amongst others, he hazarded an experiment with the arsenietted hydrogen, procured by pouring sulphuric acid on arseniate of zinc: but the gas-jar not having as much water in it as he (being near-sighted) supposed it had, and the atmospheric air above the water diluting the gas, he inconsiderately applied his mouth to draw up the atmospheric air, while the process of generation was going on, and unhappily inhaled a portion of the gas; which being highly poisonous, affected his whole nervous system, and ultimately his lungs. The case baffled the skill of his medical attendants; and although for several days no alarming apprehension was entertained, to the great grief of his father and sister, and a circle of attached friends, he died yesterday (29th)."

POISONING FROM A VIPER-BITE.

CURE WITH SULPHATE OF QUININE.

A COUNTRYMAN, forty-four years of age, was bit by a viper between the fore-finger and thumb of the right hand. On the following day, when admitted into the hospital, the whole extent of the right arm was enormously swollen, and its surface was of a livid red colour. The face and trunk had a jaundiced hue, and the extremities exhibited diffused patches of redness. There was great prostration of all the vital powers; the pulse was scarcely perceptible; the body was bedewed with a cold clammy sweat; the face was convulsed, the pupils dilated, the breathing laborious, and there were frequent efforts of vomiting. Dr. Butazzi, calling to mind the results of some cases recently published in the *Filiatre* and in the *Revue Méd.*, prescribed quinine in large doses, three grains to be taken in a spoonful of wine every hour.

On the following day, the arm remained as much swollen as before, the pulse was scarcely to be felt, and the patient com-

plained of pain in every part of his frame: the dose of the quinine was increased to four grains. On the next day there was a decided amendment; a copious warm perspiration had taken place, the discoloration of the surface abated, and the features were recovering the character of health. The swelling of the affected arm gradually from this time subsided, and, under the use of oily embrocations, altogether disappeared. Two drachms in all of the quinine were taken in the course of between two and three days.—*Filiatre di Napoli*; and *Dublin Journal*, Jan. 1837.

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE XVII.

Further consideration of the Births of Children—SINGLE AND PLURAL BIRTHS—Order of the Births—Earliest medico-legal case on record—Legal evidence of priority of Birth—Frequency of Plural Births—One or two old cases—Twins born at intervals. QUESTION OF SUPERFÆTATION—Occasions for such inquiry—Conditions of Superfætation—Illustrative Cases—Conceptions supervening at considerable intervals—Production of different Races at one Birth—Objections to the Doctrine of Superfætation—Supposed closure of the Os Uteri—Formation of a Decidua—Superfætation in a Double Uterus—Cases—General Conclusions as to the possibility of Superfætation—Authorities for and against the Doctrine.

THE next point of view in which the births of children are to be considered is as they occur singly or plurally.

SINGLE AND PLURAL BIRTHS.

Occasion and antiquity of the inquiry.—To the medical jurist the subject of plural births is important, chiefly with reference to the order in which they occur. Wherever the law of primogeniture prevails, as it does in this country, it is most material that when two or more children are born together, it should be observed, beyond the possibility of dispute, which of them came into the world first. It is worth noticing that the very earliest instance on record of the exercise of medico-legal functions, re-

lates to the ascertaining in a twin case which child was the first born. When Tamar was in labour, one of the twins which were in her womb "put out his hand; and the midwife took and bound upon his hand a scarlet thread, saying, this came out first. And it came to pass as he drew back his hand, that behold his brother came out; and she said, how hast thou broken forth? this breach be upon thee; therefore his name was called Pharez. And afterward came out his brother that had the scarlet thread upon his hand; and his name was called Zarah." (*Gen. xxxviii. 28*)

So it appears it was a midwife who took this medico-legal precaution: but we must not be scandalized by the fact of a female practitioner being the first medical jurist of whom we have any account, for the earliest medical practitioners, of whatever kind, of whom there is any authentic record, were neither more nor less than members of that respectable sisterhood—the midwives.

Legal distinctions.—In cases concerning pedigree, the declarations of relatives are admitted in evidence, to the exclusion of the testimony of mere acquaintances and menials. But the evidence of the medical attendant who may have been present at the birth, is considered superior to any other that can be adduced. The proof of primogeniture depends on the fact of which of the children was actually first delivered; for the ascertaining which fact no one has a better opportunity than the medical man who happens to assist at the labour.

There is a remarkable case on record, which shews how the law decides the question of primogeniture, where there may be no medical evidence to be had—the testimony of an eye-witness being preferred to that of any other authority. In a family of eight children, of which the three youngest were born at one time, and the five eldest died, the priority of birth of the surviving three was questioned in a

suit brought for the inheritance. The names of the children were Stephanus, Fortunatus, and Achaicus, three names which are to be found in this order at the conclusion of St. Paul's epistle to the Corinthians. Evidence was given of the declarations of the deceased father, that this was the order of their births; but this evidence was outweighed, in the opinion of the jury, by the evidence of a declaration of a deceased aunt, who was *present* at the birth, and who used to say, that she tied a string round the arm of Stephanus immediately after he was born, in order to denote that he was the second son.

Frequency of plural births.—A few remarks may here be made on the comparative frequency of twins and triplets: with a word or two on other plural births.

The proportion of twin cases varies in different countries; thus in France and Scotland the ratio is one case of twins to every 95 births; in Germany one in 80; in England one in 92; in Ireland one in every 62. It is calculated that triplets do not occur in more than one case out of 4450 (one in 6500, according to Süssmilch); nor quadruplets in above one in 100,000. Dr. Garthshore records a case in the Philosophical Transactions for 1787, where there were *five* children born at a birth; and this is perhaps the largest number born at once, recorded on good authority by any modern writer.

One or two old cases.—Were we to listen to the statements of some of the old authorities, we should find that seven, nine, nay thirty-six, have been brought forth at a birth. Sigebert, in his *Chronicles*, and Paul the Deacon, relate a curious history. A woman having given birth to seven children at once, they were immediately taken from her, and, like a litter of puppies, thrown into a pond; but Agelmund, King of the Lombards, happening to pass that way, put in his spear, when one of the infants clung to it, was taken out, reared and educated, and ultimately succeeded to the throne. Erasmus and others have noticed the remarkable fecundity of Margaret, Countess of Holland, who, in 1276, brought forth at one birth a progeny as numerous as the days in the year. They were all put into a basin together, where they died the moment they were baptized. An ingenious interpreter has given an explanation of this case, which brings the marvellous within the bounds of credibility. The Countess, instead of 365, gave birth to no more than two or three children; but happening to be confined when there were only a few days of the old year left, it was observed by some one that she brought forth as many children as there were days in the year!—and so the story spread.

Viability and other conditions of plural births.—In plural births the children are almost always diminutive, and less lively than when born singly. In twin cases, for example, each child generally weighs less than a single birth, though taken together they are heavier than a single child. It happens, however, that in some instances each of the twins is as heavy as an ordinary single child; thus Dr. Collins, in his *Practical Midwifery*, mentions a case in which he says, "both children were natural presentations: the first, a boy, weighed $7\frac{1}{2}$ pounds; the second, a girl, 8 pounds; with twenty minutes interval."

It will, perhaps, have been noticed in the table given in last lecture, that more than three children at a birth constitute a *monstrosity*, and are not capable of continuing to live. There is, I believe, no authentic example of quadruplets surviving for any considerable length of time.

The interval that may elapse between the successive births—for the births are always successive, though said to occur simultaneously—is uncertain. In midwifery practice it is not usual to allow any considerable time to intervene. If, after the lapse of half an hour, the membranes of the second child still remain unbroken, they are punctured, and uterine action thus excited: should two hours more pass away without delivery, the feet are brought down, or the forceps applied; for it is generally found that the second child is still-born, if left longer than two or three hours unassisted.

Question of Superfœtation.

There are instances of longer intervals between the births—so long as to raise the question, whether the children might not be the issue of successive conceptions, the product of superfœtation—or in other words, whether a woman already pregnant might not conceive again?

Occasions of inquiry.—I may give an example or two of the mode in which questions of superfœtation may be raised in the courts. A widow is pregnant at the death of her husband; she marries in three or four months after; at the expiration of nine months from the first husband's death, she brings forth a child, and in three months after another. Is this a case of retarded twin birth, or one of superfœtation? Again: a married woman, after having given birth to one child, may in the course of some months produce another, which is either illegitimate, or the product of superfœtation.

Finally, a woman after producing a dead child, may pretend superfœtation for the purpose of introducing a supposititious heir; or she may pretend to carry the

fruit of a second conception, with the object of enjoying the privileges and immunities of pregnancy.

In all such cases it will obviously be the duty of the medical jurist to inquire, first, whether the supernumerary pregnancy exist, and then to ascertain, if possible, whether it be really a superfetation, or only a retarded birth.

Conditions of superfetation.—Whatever be the issue brought forth at one birth, or about the same time (unless it consist of different races—as a white, or a negro, and a mulatto), may reasonably be imputed to a single conception.

Again, there are numerous examples of mature fetuses being born along with others which appear to be no more than three, four, five, or six months. In such cases it is not necessary to have recourse to the supposition of superfetation, for we can conceive the immature offspring to have ceased to be developed at the age which it indicates; and even though such issue be born successively, they do not necessarily imply successive conceptions.

Nor, if two children be born with about a month of difference in the time of birth, yet the first appear somewhat immature, say with the characteristics of an eight months fetus, while the second is perfectly mature, does this imply distinct conceptions.

But when we find two mature children, born of the same woman, with two or three or more months between the births, the supposition is inevitable that there has been superfetation. The interval of some days, seven, for instance, ten, seventeen, or twenty (for there are cases to this extent reported), do not warrant our inferring the issue, though ma-

ture, to be other than twins: even a month may only leave the question doubtful.

Examples.—Among the cases cited by Haller, there are the following:—Successive births, with an interval of two months, each perfect; a fetus born three months after another, both living and healthy; one born six months after another, but feeble; two lively and strong fetuses, one born on the 31st July, the other on the 9th February, so that the latter must have been conceived when the former was about eighty days old in intra-uterine life.

Some cases more recent are perhaps not less remarkable. Mary Ann Bigaud, a woman of Strasburg, aged 37, was delivered of a lively child on the 30th April. The lochia were presently suppressed, and so was the milk: in short, on the 17th September following she brought forth another apparently mature and healthy child, that is to say, in about four months and a half after the first,—which could not well occur without superfetation. The woman died seven years after; and it was expected that she would be found to have a double uterus; but there was nothing abnormal detected about the womb when the body was examined.

It may as well be mentioned here, that such a thing as a true double uterus has never been discovered in the human species; that is to say, two cavities, with a pair of fallopian tubes, ovaries, and appendages, attached to each; but there have been frequent instances of bilocular uteri, with the fundus double, and a septum in some cases continued down into the vagina; the latter peculiarity, however, is comparatively rare, and the more common form of abnormal structure is of this kind. This drawing represents a vir-

FIG. 21.—Example of a bilocular Uterus.

gin uterus which was partially bilocular. The length from the fundus to the os uteri was $3\frac{1}{2}$ inches; the greatest breadth 3 inches; and the length of the septum found between the two cavities into which the internal space was divided, measured $1\frac{1}{2}$ inch*.

A very remarkable case, which can scarcely be accounted for without admitting the possibility of superfœtation, was observed by Dr. Desgranges, of Lyons. A woman was delivered of a seven months' child; none of the usual consequences of delivery ensued; but in five months sixteen days afterwards, another infant was brought forth, which had apparently reached its full time. The only mode of evading the admission of superfœtation here seems to be, by insisting that the so-called seven months' child was no more than a four months' fœtus; or, in other words, that the first was a mere abortion, and the second mature. But it is very unlikely that an immature fœtus of four months (at which age no fœtus has been known to survive birth) would be mistaken for a lively infant of seven months. If, on the other hand, we admit this infant to be what it was represented, and still deny superfœtation, we are driven to the absurdity of supposing, that the period of utero-gestation with a living healthy child might extend to upwards of twelve months!

Some of the opponents of superfœtation endeavour to shew, that in every case so reputed, there must either be a double uterus, or the first birth is premature, though mature to all appearance. We cannot deny the possibility of the first supposition, yet we see that it was gratuitous and unfounded in the case already quoted, as it was in some others. But it is hard to admit that the second supposition is tenable: who can allow that a fœtus of five, six, or seven months, should have all the characteristics of a nine months' child, so as to be mistaken for such? The development of the embryo and fœtus is too regular to justify the supposition of such an anomaly in any circumstances.

The late Dr. Maton published a valuable case in the fourth volume of the Transactions of the College of Physicians. An Italian lady, married to an English gentleman, gave birth to a male child, at Palermo, on the 12th November, 1807; it had every appearance of health, though it died in nine days, owing to some distressing circumstances connected with the accouchement;—the lady, it appears, was hastily delivered on a bundle of straw, in an empty house, at midnight. On the 2d of February, 1808 (*three months minus ten*

days from her first confinement), she was delivered of another male infant, completely formed, and in perfect health.

It was objected to this case, that the first child was probably not "completely formed," as the second alone was said to be; and that therefore it was no more than a case of twins, in which one of the fœtuses came into the world at the sixth, and the other at the ninth month of pregnancy, the ova being quite distinct and separate: the proof was deficient, it was urged, that the first child had reached the full term of utero-gestation. Dr. Paris informs us, that in consequence of these objections (which were made by Dr. Granville), he applied to Dr. Maton for further explanation, when he was told "that both the children were born perfect, the first therefore could not have been a six months' child;" nor were the "distressing circumstances" of such a nature as to cause the labour to be premature. According to Dr. Maton, the facts were these:—"The lady could not obtain better accommodation at the time; the labour, although quick, was not sudden, for the accoucheur was already in attendance; nor was it premature, for the natural period of utero-gestation was supposed to have been completed."

This seems to be the most complete and authentic case of superfœtation on record—the births, mature and lively, having followed each other at such an interval as to render the admission of one conception supervening on another, after a lapse of two or three months, inevitable.

Mongrel offspring.—It is handed down to us in the records of the olden time, that a woman has sometimes betrayed her adultery by bringing forth two children at a birth—one resembling her husband, the other her paramour; like Alcmena, when she bore Hercules and Iphicles, severally begotten by Jupiter and Amphitryon.

Different races.—But this is only questionable evidence of superfœtation, compared with the striking fact of females producing plural births of mixed varieties—for instance, a white and a mulatto at once.

Haller was not acquainted with any cases of this kind, or he would infallibly have quoted them. Since he wrote, however, several have been placed on record.

Dr. Gern, of Wittemberg, gives an account of a woman, who, after sexual intercourse with a European and then with a negro, brought forth twins, one of which was white, and the other a mulatto.

M. Delmas relates a case in the *Annales de Montpellier* for 1806. A woman, aged 36, was delivered, in the eighth month of her pregnancy, of a white child and a mulatto. Both died soon after. The placentæ were intermixed; and the woman

and that she had had intercourse with a negro when she was four or five with child.

Wences published a similar case in which a white maid-servant bore twins, one white and of European structure, the other dark, and of the negro type.

Seale tells us of a negress, who was the mother of twins in the West Indies, one black, the other a mulatto. M. Wilson, Oslander, and others, relate numerous instances of black and tawny twin children.

These are matters of fact, which cannot be invalidated by mere theory; for objections to the doctrine of superfœtation are no more than theoretical.

Objections.—Many opponents of superfœtation deny the fact on the ground of the closure of the os uteri. They hold that the first consequences of conception are the closure of the os uteri—some say immediately, others after a short time. But evidence is there of such an occurrence, which, if admitted, must preclude the possibility of further question? I imagine, of a very conclusive nature. While the contrary supposition, that the os uteri is not immediately closed, but remains open for at least some time, seems to rest on quite as good grounds.

Objection of the os uteri.—This objection, taken at the time, and the more obstinately maintained, perhaps, for that reason, is certainly untenable, for it is not supported by fact or experience. Women, we have seen, sometimes continue to menstruate for a few periods after conception, some have continued to do so throughout their pregnancy. What can be a stronger proof of the patency of the uterine orifice? But there is a more conclusive one: the catheter and the finger can be introduced, without obstruction, into a pregnant uterus.

Haller says on the point is so clear and precise as to show that his mind was perfectly satisfied. "*Claudius Galenus [os uteri] legas a conceptu, et analogia brutorum animalium. nihil est ejusmodi.*" And again: "*uteri nunquam clausum est, ideoque superfœtari non solum a die, sed et trigessimis, aut primis duobus mensibus, sed omni omnino tempore.*" After stating all the arguments for and against the doctrine, with his usual perspicacity, he concludes the subject by expressing his opinion that there is no valid objection to the possibility of superfœtation occurring while yet the ovum has not become fully developed. These are his words:—"Nihil ergo repugnat quo tempore non dum prægravidæ est, quin læta ad aliam sedem uteri se

adaptet, novusque eo loco fœtus subnascatur."

2. *Formation of the decidua uteri.*—John Hunter demonstrated the formation of a deciduous membrane lining the uterus, as one of the earliest consequences of conception. The existence of such a membrane has been urged by Roose and others, as fatal to the hypothesis of superfœtation.

And are all our facts and instances to fall at once before this membrane? Is the growth of the decidua so invariable, and when present is it so well developed and firm as always to resist the impulse of generation? Experience is clearly one way, while theory is the other. Nor can that theory be urged now with the same force that it once was: its supporters imagined that the decidua, in lining the uterus, covered over the apertures of the fallopian tubes. That part of their doctrine proves to be untrue; the decidua does not close the fallopian orifices, and any resistance which it can afford to a second conception must be over the cervix uteri; and recollect that the os uteri is not necessarily closed. That a certain degree of resistance (perhaps even a considerable degree) is exerted by this membrane, we are by no means disposed to deny; it may indeed be owing to this that superfœtations are not more frequent: but because the occurrence may thus be rendered impossible in many cases, does it therefore follow that it is so in all?

In a valuable paper communicated to the Medico-Chirurgical Society, by Dr. Robert Lee, the objection just referred to is revived. The case on which the paper is founded is that of a woman who died of peritonitis, eight days after parturition, and who proved, on examination of her body, to have had a double, or rather bifid, or bicorned, uterus. Here is the appearance of the uterus, as displayed by Dr. Lee. The right cornu had contained the fœtus (and, by the way, the deceased had borne several living children previously); the left was about the ordinary size of the unimpregnated uterus. This latter cornu was lined with a deciduous membrane, forming a shut sac towards the cervix, but it is remarkable that the fallopian tube was not closed, the membrane passing into the opening and leaving it completely pervious.

The discovery of a deciduous membrane in the unimpregnated cornu, appears to Dr. Lee to be of much importance. He thinks it probable that a decidua is similarly formed in every case of double uterus where either of the cornua is impregnated, and he adduces the instance of what occurs in the lower animals, "the membrane which surrounds the product of conception invariably occupying the

FIG. 22.—Double or Bicorn Uterus.

a, The cervix; b, Orifice of the fallopian tube; c, Left cornu, lined with decidua; d, Right cornu, which had recently contained a fetus.

whole inner surface of both cornua." Hence he argues the impossibility of superfetation, even in cases which would seem most favourable to it—namely, where the uterus is bicorn. "The disposition of the deciduous membrane," says he, "in the case I have now related, must have rendered superfetation, or the conception of a second embryo during gestation, impossible, and its history tends entirely to overturn the recent speculations of M. Cassan also, on the possibility of superfetation where a double uterus exists. Menstruation must have been equally impossible in this case as in ordinary pregnancy, where the inner surface of the uterus is lined with decidua*."

I must confess, that notwithstanding these very imposing statements, it still appears to me that the proof of Dr. Lee's position is by no means made out. We have

here but a single case, and notwithstanding the analogy from the lower animals by which it is backed, further examples will be required in the human species before a general conclusion can be drawn. Should it happen, too, that such a structure is found general, it must still be admitted that it may not be equally perfect in all cases, for theory must be subservient to facts, not facts to theory.

It may be added, that perhaps this case no more disproves the possibility of superfetation, than it does the fact of menstruation during pregnancy. Dr. Lee says that menstruation was "equally impossible" with superfetation in this case. Now, as it is generally admitted by some of the most experienced accoucheurs that menstruation may, and often does, occur, at least once or twice, after conception, I am inclined to infer that, in all pregnant women, the decidua is not to be found exactly as in the case just described.

* MEDICAL GAZETTE, vol. xi p. 176

But if the existence of such a decidua as Dr. Lee found over the cervix be admitted as an argument against superfœtation, another point which he noticed in the same case seems strongly in favour of it—namely, the open state of the fallopian tube. Had this been closed, it were then, indeed, perhaps impossible that superfœtation should take place; but being open, what insuperable obstacle can there be to the generative influence finding its way to the ovary, and thus effecting a new conception? Only allow that the first ovum does not completely fill the uterus, and that there is still access to one of the ovaries through a fallopian tube, and there can be no great hazard in supposing that even if there were a decidua uteri forming a shut sac, it would not in all cases present an unimpregnable barrier.

The learned Sir Thomas Browne makes some remarks on the subject, which I shall take leave to quote, not exactly through deference for his physiology, but for his comprehensive and sound understanding. It will be observed in the outset, that he is of the number of those who believe the womb closed upon the occurrence of conception; he does not, however, consider that this decides the impossibility of superfœtation. “Although it be true that upon conception the inward orifice of the matrix exactly closeth, so that it commonly admitteth nothing after, yet falleth it out sometimes, that in the act of coition the avidity of that part dilateth itself, and receiveth a second burden; which, if it happen to be near in time unto the first, they do commonly both proceed unto perfection, and have legitimate exclusions, periodically succeeding each other. But if the superfœtation be made with considerable intermission, the latter most commonly proves abortive; for the first being confirmed, engrosseth the aliment from the other. However, therefore, the project of Julia seem very plausible, and that way infallible, when she received not her passengers before she had taken in her lading, yet was there a fallibility therein; nor, indeed, any absolute security in the policy of adultery after conception. For the matrix (which some have called another animal within us, and which is not subjected unto the law of our will), after reception of its proper tenant, may yet receive a strange and spurious inmate, as is confirmed by many examples in Pliny, by Larissæa in Hippocrates, and that merry one in Plautus, urged also by Aristotle.*”

Superfœtation during extra uterine pregnancy.—There is another condition in which superfœtation may occur, namely, where

the product of the first conception is extra-uterine. I have already noticed a remarkable instance in which a woman bore two or three children successively, while she had a foetus in one of the fallopian tubes. Another example may be mentioned. During the existence of extra-uterine pregnancy a woman conceived again, and in due time was delivered of a mature infant. It became necessary, in consequence of some accidents which supervened, to give issue to the retained foetus: gastrotomy was practised, when an infant was extracted which had been viable, but was now partially decomposed through its long sojourn in the abdomen. The patient recovered.

Another instance may be quoted. Dr. Clet, of Lyons, in the year 1818, opened the body of a woman who had recently died. Behind the uterus, and a little to the right, he found a foetus weighing five ounces, three drachms, and measuring eight inches and a half long. It had attained the fifth month of development. In the uterus was a second foetus, of about the third month.

Superfœtation with a double uterus.—In M. Cassan's thesis (On Double Uterus and Superfœtation, Paris, 1826), there is the history of a case which occurred in the celebrated Mde. Boivin's practice. On the 15th of March, 1810, a woman, aged forty, gave birth to a female infant weighing about four pounds. As the abdomen still remained bulky, Mde. Boivin introduced her hand, but could find nothing in the uterus. Further examination led her to suspect that there was another foetus, either extra-uterine or contained in a second cavity of the womb. At length, on the 12th May, a second female infant was born, weighing not more than about 3 lbs., feeble, and scarcely able to respire. The mother assured Mde. Boivin that she had had no connexion with her husband (from whom she was for some time separated) except thrice in two months, namely, on the 15th and 20th July, 1809, and the 16th September following. The product of the second conception was here perfectly distinct and separate from the first; and the uterus was bilocular.

This is, I believe, the only authentic example on record of superfœtation taking place in a double uterus, although such a structure is generally admitted to be adapted for such an occurrence. Nor indeed are twin cases common in bilocular uteri: when women with this form of womb become pregnant, they generally bear but one foetus, as in Dr. Lee's case, a case described by Tiedemann in Meckel's *Archiv* for 1819, and one by Oslander, in which both the uterus and vagina were

* *Inquiries into Vulgar and Common Errors*, p. 118. Ed. 1696.

completely divided. But there is at least one instance on record of double pregnancy in a double uterus, — in Rust's *Magasin*, Band. xxvii. H. 1. Whether it was a case of superfœtation or not, seems uncertain; but one of the fœtuses, that in the right cavity, was larger than the other: the infant from the left side died on coming into the world.

General conclusions.

The following general conclusions seem to be warranted by what has been already said. Superfœtation is possible,—

1. When sexual intercourse is repeated soon after conception: in this way only can we account for distinct varieties, or different races, produced at one birth—such as white or black, and mulatto children.

2. When the product of the first conception is extra-uterine, or the womb partially occupied by a mole, or a dead or disorganized fœtus.

3. When the uterus is double; for, notwithstanding the theory of a decidua, which would seem to preclude such an inference, facts just referred to cannot be disputed. Where the uterus is perfectly bilocular, and no morbid condition interferes, it is difficult even theoretically to assign a plausible reason against the doctrine.

4. In every case where the uterus is not closed (and the closure, as we have seen, is not general), and where the product of the first conception does not, by its considerable size and the space it occupies in the womb, obstruct all access to one of the fallopian tubes, we cannot but admit the possibility.

5. And lastly, it is unavoidable to admit the fact of superfœtation, when we see lively and mature infants born of the same woman at an interval of three, four, five, or six months between the births. The limit of the interval between successive conceptions during pregnancy is uncertain: Weber hesitates not to extend it to the seventh month; nor does Haller dissent from his opinion.

In the preceding discussion I have avoided any appeal to authorities in the shape of an *argumentum ad verecundiam*, partly because I thought that a reference to facts would be far more profitable, but chiefly because the said authorities have been much divided. In conclusion, however, I need not hesitate to mention that if Hebenstreit, Ludwig, Metzger, Roose, Schmidtmüller, and Blumenbach, be opposed to the doctrine, there are, on the other side, the names of Haller, Harvey, Alberti, Teichmeyer, Ploucquet, Bernt, Henke, Mende, Martini, and most of the modern French school.

Orfila's opinion (in which Devergie

coincides) is guarded in the extreme. I shall quote it, not because I approve of the cautious timidity with which it is expressed, but because, as it seems wrong from the author, it may possibly be entitled to the credit of being the better weighed. After reviewing most of the well-attested cases he could find on the subject, he sums up to this effect, "that the medical jurist ought to admit the possibility of superfœtation, but he ought at the same time to recollect, that cases occur in which it is extremely difficult to prove that it has taken place, the additional children being readily accounted for either as abortions or twins."

LECTURES

ON

MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, Esq., F.L.S.

LECTURE LV.

IN this lecture I propose to examine the family

POLYGONACEÆ,

the most important officinal substance obtained from which, is rhubarb; the produce of some species of

Rheum.

History.—Dioscorides speaks of a root which he calls *Rha*, or *Rheon* (ῥὰ ῥήον), and which has been regarded by some as identical with our rhubarb; but the description he has given of it does not apply to the latter substance, and it is, therefore, fair to presume some other root must have been meant. "*Rh*," by some called *Rheon*, by the Latins *Rhaponticum*, grows," says Dioscorides, "in those countries which are beyond the Bosphorus, and from which it is brought. It is a black root, similar to great century, but smaller and redder, spongy, somewhat smooth, and odourless." Pliny gives a similar account of it, under the name of *Rhacomia*: it comes, he says, from the countries beyond Pontus, resembles the black costus, is odourless, and has a hot astringent taste.

Prosper Alpinus was of opinion that the *Rha* of Dioscorides was the root of *Rheum Rhaponticum*, which Alpinus obtained from Thracia in 1608, A.D. and cultivated at Pavia.

The later Greek writers are supposed to have been acquainted with our rhubarb. Preind says Alexander of Tralles, first mentioned it in weakness of the liver and dysentery. Paulus Ægineta seems to make a distinction between *Rha* and *Rheon*. In the first chapter of the first book of his work, he says, that, for the crudities and vomiting of pregnant women, we may give "the blood-wort, boiled in water, for drink; and likewise dill, and the Pontic root, called *Rha*, in the dialect of that country." In the forty-third chapter of the same book, in noticing the practice of the ancients, he says, "Alvine discharges they promoted by giving turpentine to the extent of an olive, when going to rest; or, when they wished to purge more effectually, by adding a little rhubarb (*Rheon*)." This is the first notice of the purgative properties of rhubarb.

In one of the Arabian authors (Mesue, the younger), we find three kinds of rhubarb mentioned: the Indian, said to be the best, the Barbarian, and the Turkish, which is the worst of all.

Botanical history.—It may not be out of place here, to offer a slight sketch of the opinions of naturalists regarding the plant which furnishes our rhubarb. For a fuller account, I must refer those interested in this inquiry to the late Dr. Duncan junior's Supplement to the Edinburgh New Dispensatory.

Formerly this root was supposed to be obtained from the *Rheum Rhaponticum*. In 1732, the *R. undulatum* was sent from Russia to the Jussieus at Paris, and to Rand of Chelsea, as the true rhubarb. This is the species which Linnæus described as *R. Rhabarbarum*. About 1750, at the desire of Kauw Boerhaave, first physician to the Emperor of Russia, the senate commissioned a Tartarian merchant, a dealer in rhubarb, to procure them some seeds of the genuine plant. This he did, or pretended to do; and on sowing them, two species of *Rheum* were obtained—namely, the *undulatum* and the *palmatum*. In 1762, seeds of the latter species were received by Dr. Hope, of Edinburgh, from Dr. Mounsey, at Petersburg; they were sown, and the plants cultivated with success. The root of this species being found to agree, in many of its characters, with that of genuine rhubarb, led to the belief that the *palmatum* was the true species. The inquiries of Pallas, however, raised some doubts about the correctness of this opinion; for the Bucharrians declared themselves unacquainted with the leaves of the *palmatum*, and described the true plant as having round leaves, with a few incisions only at the margin. This description agreed best with *Rheum compactum*, the roots of which were declared, by

Millar, who cultivated the plant, to be as good as foreign rhubarb. Georgi relates, that a Cossack pointed out to him the leaves of the *R. undulatum* as the true species. These accounts were not satisfactory to the Russians, and in consequence, in 1790, Sievers, an apothecary, went to Siberia, under the auspices of Catherine II., with a view of settling the question; but after four years of persevering attempts to reach the country where the true rhubarb grew, or even to obtain the seeds, he was obliged to be satisfied with negative results only. "My travels," says he, "as well as my acquaintance with the Bucharrians, have satisfied me that as yet nobody—that is, no scientific person—has seen the true rhubarb plant. All that is said of it by the Jesuits, is miserable confused stuff; all the seeds procured under the name of true rhubarb are false; all the plantations, from those of the Knight Murray down to the flower-pot of a private individual, will never yield true rhubarb. Until further determination, I hereby declare all the descriptions in all the *Materia Medicas* to be incorrect." The inflated style of this person, does not, however, increase our confidence in his statements.

Four species of *Rheum*, growing on the Himalayan Mountains, have been described by my friends, Dr. Wallich and Mr. Royle. Of these, one (namely, the *Rheum Emodi*, culled also *R. australe*) was at first supposed to be one of the sources of our officinal rhubarb, though without sufficient reason. I have specimens of the Himalayan rhubarb collected and dried by the natives, and which were given me by Dr. Wallich: they are probably the produce of *R. Emodi*, or *Webbianum*, and have hardly any resemblance to the rhubarb of the shops.

Mr. Royle, in his "*Illustrations of the Botany of the Himalayan Mountains*," after referring to the accounts of different authors, as to the precise locality of the country yielding Russian rhubarb, concludes that it is "within 95° of E. long. in 35° of N. latitude—that is, in the heart of Tibet." And he adds, "as no naturalist has visited this part, and neither seeds nor plants have been obtained thence, it is as yet unknown what species yields this rhubarb."

Characters of the genus Rheum.—The genus *Rheum* is characterized by having hermaphrodite flowers, consisting of a coloured perianthium, composed of from six to nine pieces, arranged in two rows; nine stamina inserted on the torus at the base of the perianthium, free or subconnate at their base; a simple triangular ovary, supporting three styles, which are each furnished with a peltato-capitate

elapses from the time of its collection until it is ready for exportation.

Physical properties and varieties.—In English commerce four kinds of rhubarb are known, namely, *Russian*, *East Indian* or *Chinese*, *Dutch—trimmed*, and *English*.

1. *Russian rhubarb*.—This is the kind known in the shops by the name of *Turkey rhubarb*, because it is said to have been brought formerly to this country by way of *Natolia*. It is now imported from *Petersburgh*. It is described in books by the names of *Muscovite*, *Bucharian*, or *Siberian rhubarb*.

According to the treaty entered into by the *Russians* and *Chinese*, all the commerce between the two nations is transacted at the frontiers. *Kiachta* is the *Russian*, *Maimatschin* the *Chinese* frontier town. All the so-called *Russian rhubarb* is brought to *Kiachta* by *Bucharian* merchants, who have entered into a contract to supply the government with that drug in exchange for furs. It is there examined with much care in the presence of the *Bucharians*, by the apothecary stationed at *Kiachta* for the purpose. The worm-eaten pieces are rejected, the others bored to ascertain their soundness, and all the damaged or decayed parts are cut away. In accordance with the terms of the contract, the pieces which do not pass examination are burned; the remainder is then transmitted to *Petersburgh*, and from thence to us.

It is imported in boxes or cases, covered with a pitched cloth, on the outside of which is a hide. The size of the pieces are various; but in commerce the small pieces are preferred, and they are, therefore, picked out and sold as *radix rhei turcici electa*,—the larger pieces and the dust being employed for powdering. Their shapes are various, being angular, rounded, irregular, &c. The external appearance of many of the pieces seems to show that the cortical portion of the root had been shaved off longitudinally by successive strokes of a knife: hence the angular appearance of the external surface. Holes are observed in many of the pieces: some of them extend completely, others only partially through. Those which extend only to the centre of the pieces have been evidently made for the purpose of examining the condition of the interior of the rhubarb.

Externally the pieces are covered with a bright yellow coloured powder, usually said to be produced by the mutual friction of the pieces in the chests during their passage to this country, though many druggists believe it is derived from the process of *rouncing* (that is, shaking in a bag with powdered rhubarb), before its

exportation. The odour is strong and peculiar, but somewhat aromatic: it is considered by druggists to be so delicate that in all wholesale houses a pair of gloves is kept in the *Russian rhubarb* drawer, with which only are the assistants permitted to handle the pieces. When chewed it feels gritty under the teeth, from the presence of numerous crystals of oxalate of lime; it communicates a bright yellow colour to the saliva, and has a bitter, slightly astringent taste.

Beneath the dust with which the pieces are covered, the surface has a reddish white tint, owing to the intermixture of white and red parts. The yellowish white parts have the form of lines or veins, which, by their union with each other, assume a reticular form. Irregularly scattered over the surface we observe small star-like spots and depressions, of a darker colour. The transverse fracture is uneven, and presents numerous brownish red or dark carmine coloured undulating veins. The longitudinal fracture is still more uneven, and shows the longitudinal direction of the veins, which are often interrupted with white. The surface obtained by cutting is more or less yellow, and often exposes the veins, disposed in groups.

By boiling very thin slices of the root in water, and then submitting them to the microscope, we observe cellular tissue, annular ducts, and numerous clumps of crystals of oxalate of lime (fig. 150). Turpin con-

FIG. 150.—Crystals of Oxalate of Lime in *Russian Rhubarb*.

sidered the presence of these crystals sufficient to distinguish *Russian* and *Chinese* rhubarb from that grown in *Europe*; but in some specimens of *English* rhubarb I have met with these crystals in as great abundance as in foreign rhubarb. According to *Raspail*, these crystals exist in the interstices of the elongated cellular tissue.

The powder of *Russian rhubarb* is of a bright yellow colour, with a reddish tint; but as met with in the shops, it is almost invariably mixed with the powder of *English* rhubarb.

stigma. The fruit is a three-sided caryopsis, winged at the angles, and surrounded at the base by the perianth; the seeds are albuminous, with a central straight embryo.

From this description it will be evident that the genus belongs to class *Enneandria*, order *Trigynia*, of the Linnæan arrangement.

The species hitherto known, agree in possessing large fleshy branching roots, which are brown externally, and yellow, intermixed with red, internally; radical and petiolated leaves; membranous ochrea; and numerous small flowers, arranged in panicles or compound racemes.

The *Rheum palmatum*, fig. 147 (the species

assumed, in the London Pharmacopœia, as the source of the rhubarb of the shop) is distinguished from other species by its palmated form of its leaves; the clefts between the segments being somewhat dilated, the laciniae acuminate. On the upper surface the leaves are roughish, and of a dull-green colour; on their under surface, they are pale and villous. The petioles are slightly furrowed above, and are rounded at the edges. This species grows wild on the mountains of Chinese Tartary, and in Tibet. It is cultivated both in England and Scotland, for the root; which, when dried and properly prepared, constitutes the "*English rhubarb*" of our druggists.

FIG. 147.—*Rheum palmatum*.

FIG. 148.—*Rheum compactum*.

Rheum compactum (fig. 148) has very obtuse, shining, smooth leaves, somewhat lobed, with small teeth. It is a native of Tartary and China.

Rheum australe or *Emodi* (fig. 149) has roundish, cordate, obtuse leaves, rough beneath and

on the margin, with the sinus at the base dilated, and with furrowed roundish footstalks. The branches and peduncles are papillose—scabrous; the leaflets of the perianth oval oblong, finely crenate at the apex. It grows in Chinese Tartary and in the Himalayas.

Preparation.—We are yet in want of a good account of the method followed in preparing Asiatic rhubarb for the market. It is probable, however, that the process varies in different places, since the accounts given by Bell and Sievers do not precisely agree. Bell says, that after digging and gathering the rhubarb, the Mongalls cut the large into small pieces, in order to make them dry more readily, and make a hole in the middle of every piece, through which a cord is drawn, in order to suspend them in any convenient place. They hang them for the most part about their tents, and sometimes on the horns of their sheep. Sievers, however, states, that the roots are cut in pieces, strung upon threads, and dried under sheds so as to exclude the solar rays; and the same author tells us that sometimes a year

FIG. 149.—*Rheum Emodi* or *australe*.

elapses from the time of its collection until it is ready for exportation.

Physical properties and varieties.—In English commerce four kinds of rhubarb are known, namely, *Russian*, *East Indian* or *Chinese*, *Dutch*—*trimmed*, and *English*.

1. *Russian rhubarb*.—This is the kind known in the shops by the name of *Turkey rhubarb*, because it is said to have been brought formerly to this country by way of *Natolia*. It is now imported from *Petersburgh*. It is described in books by the names of *Muscovite*, *Bucharian*, or *Siberian rhubarb*.

According to the treaty entered into by the Russians and Chinese, all the commerce between the two nations is transacted at the frontiers. *Kiachta* is the Russian, *Maimatschin* the Chinese frontier town. All the so-called Russian rhubarb is brought to *Kiachta* by *Bucharian* merchants, who have entered into a contract to supply the government with that drug in exchange for furs. It is there examined with much care in the presence of the *Bucharians*, by the apothecary stationed at *Kiachta* for the purpose. The worm-eaten pieces are rejected, the others bored to ascertain their soundness, and all the damaged or decayed parts are cut away. In accordance with the terms of the contract, the pieces which do not pass examination are burned; the remainder is then transmitted to *Petersburgh*, and from thence to us.

It is imported in boxes or cases, covered with a pitched cloth, on the outside of which is a hide. The size of the pieces are various; but in commerce the small pieces are preferred, and they are, therefore, picked out and sold as *radix rhei turcici electa*,—the larger pieces and the dust being employed for powdering. Their shapes are various, being angular, rounded, irregular, &c. The external appearance of many of the pieces seems to show that the cortical portion of the root had been shaved off longitudinally by successive strokes of a knife: hence the angular appearance of the external surface. Holes are observed in many of the pieces: some of them extend completely, others only partially through. Those which extend only to the centre of the pieces have been evidently made for the purpose of examining the condition of the interior of the rhubarb.

Externally the pieces are covered with a bright yellow coloured powder, usually said to be produced by the mutual friction of the pieces in the chests during their passage to this country, though many druggists believe it is derived from the process of *rouncing* (that is, shaking in a bag with powdered rhubarb), before its

exportation. The odour is strong and peculiar, but somewhat aromatic: it is considered by druggists to be so delicate that in all wholesale houses a pair of gloves is kept in the Russian rhubarb drawer, with which only are the assistants permitted to handle the pieces. When chewed it feels gritty under the teeth, from the presence of numerous crystals of oxalate of lime; it communicates a bright yellow colour to the saliva, and has a bitter, slightly astringent taste.

Beneath the dust with which the pieces are covered, the surface has a reddish white tint, owing to the intermixture of white and red parts. The yellowish white parts have the form of lines or veins, which, by their union with each other, assume a reticular form. Irregularly scattered over the surface we observe small star-like spots and depressions, of a darker colour. The transverse fracture is uneven, and presents numerous brownish red or dark carmine coloured undulating veins. The longitudinal fracture is still more uneven, and shows the longitudinal direction of the veins, which are often interrupted with white. The surface obtained by cutting is more or less yellow, and often exposes the veins, disposed in groups.

By boiling very thin slices of the root in water, and then submitting them to the microscope, we observe cellular tissue, annular ducts, and numerous clumps of crystals of oxalate of lime (fig. 150). Turpin con-

FIG. 150.—Crystals of Oxalate of Lime in Russian Rhubarb.

sidered the presence of these crystals sufficient to distinguish Russian and Chinese rhubarb from that grown in Europe; but in some specimens of English rhubarb I have met with these crystals in as great abundance as in foreign rhubarb. According to *Raspail*, these crystals exist in the interstices of the elongated cellular tissue.

The powder of Russian rhubarb is of a bright yellow colour, with a reddish tint; but as met with in the shops, it is almost invariably mixed with the powder of English rhubarb.

According to Hornemann, Russian rhubarb is composed of—

Rhabarbarin of Pfaff	16.042
Yellow colouring matter of Henry	9.583
Bitter astringent extract	14.687
Oxydized tannin	1.458
Mucilage	10.000
Matter extracted from the fibre by potash ley.....	28.333
Oxalic acid contained in the potash ley	1.042
Insoluble residuc	14.583
Loss in drying the root	3.333
Loss in the analysis	0.939
	<hr/>
	100.000

70 grains of the insoluble residuc obtained from 1 ounce of Russian rhubarb, gave 33 grains of ashes, composed of a trace of potash, 1 grain carbon, 2 grains silicic acid, 1 grain carbonate of magnesia, 1 grain alumina with a trace of oxide of iron, and 28 grains of carbonate of lime.

White or Imperial rhubarb.—When Pallas was at Kiachta, the Buchanarian merchant who supplied the crown with rhubarb brought some pieces of white rhubarb, which had a sweet taste, and was equal in its effects to the best sorts. It is said to be the produce of *Rheum Leucorhizon* of Pallas (the *R. nanum* of Sievers). A good account of it, with coloured figures, will be found in the "*Pharmaceutische Waarenkunde*" of Gæbel and Kunze. Some of the specimens of Russian rhubarb brought to this country have a much whiter appearance than is usually observed.

2. *China or East Indian rhubarb.*—The rhubarb known in commerce by the name of East Indian, or Chinese, is brought to this country either directly from Canton, or indirectly by Singapore, and other parts of the East Indies. It is imported in chests of thin wood, lined with lead. The pieces are frequently cylindrical or roundish, but sometimes flattened; in trade they are distinguished as *rounds* and *flats*. They appear to have undergone a different process of preparation to that of Russian rhubarb. Thus the cortical portion of the root seems rather to have been scraped than sliced off, and hence the surface is not so angular; and on the worst pieces we observe the remains of the greenish-brown or blackish cortex. Among druggists this kind of rhubarb is frequently termed *half-trimmed*, or *untrimmed rhubarb*. The pieces are generally perforated with holes, in many of which we find portions of the cords by which the pieces were suspended. These holes are smaller than those observed in Russian rhubarb, and

that portion of the root forming their sides is usually dark-coloured, decayed, and of inferior quality. The best pieces of this sort of rhubarb are heavier and more compact than those of the Russian kind; they are covered with an easily separable yellow dust. When this is removed we observe that the surface is not so regularly reticulated, is more of a yellowish-brown than reddish-white colour, and has coarser fibres than Russian rhubarb. On the finer pieces we notice numerous star-like spots or depressions. The fracture is uneven; the veins, especially towards the middle, have a less determinate direction, and are of a duller or reddish-brown, and, in very bad pieces, of an umber-brown colour, with a grey substance between the veins.

The odour of this species is much less powerful than that of Russian rhubarb, and is somewhat less aromatic. The taste, grittiness when chewed, and microscopic appearances, are similar to those of Russian rhubarb. The colour of the powder is of a more dull yellow or brownish cast.

Hornemann analysed this species of rhubarb under the name of English rhubarb. Its constituents were as follows:—

Rhabarbarin of Pfaff	14.375
Yellow colouring matter of Henry	9.166
Bitter astringent extract	16.458
Oxydized tannin	1.249
Mucilage	8.333
Matter extracted from the fibre by potash ley	30.416
Oxalic acid contained in the potash ley	0.833
Insoluble residuc	15.416
Loss in drying the root	3.125
Loss in the analysis	0.629
	<hr/>
	100.000

Seventy-four grains of the insoluble residuum obtained from one ounce of Chinese rhubarb gave 39 grains of ashes, composed of a trace of potash, 1 grain carbon, 2 grains silicic acid, 1 grain carbonate magnesia, 1 grain alumina with a trace of iron, 34 grains carbonate lime.

3. *Dutch-trimmed rhubarb.*—In English commerce there is met with a kind of rhubarb known by the name of *Dutch-trimmed* or *Batavian*, and which is brought from Canton and Singapore. It is well known to druggists, and is always quoted in price-currents as a distinct kind. It is not improbable that it is the kind described by Guibourt and others under the name of *Persian rhubarb*. It is imported in chests, each containing from 130 to 140 pounds. In shape, size, and general appear-

resembles the Russian kind; for a portion of the root seems to be separated by slicing, and hence have the same angular appearance of surface that the Russian rhubarb has.

The pieces are frequently perforated in the holes are found the cord by which the root has been divided. In the drug trade this rhubarb is said to be *trimmed*, and to the shape of the pieces they are *flats* or *rounds*. The colour and the pieces are variable.

Himalayan rhubarb.—As already mentioned, it is probably the produce of *Rheum* and *Webbianum*. It has very much resemblance to the rhubarb of the pieces which I have, were procured by Dr. Wallich from the natives, and strung them around the necks of the pieces. The pieces are cylindrical, cut obliquely at the extremities; the bark of the root is not removed; the colour is dark brown, with a slight tint of grey; they are without odour, and have a spongy texture. Mr. Royle says that Himalayan rhubarb makes its way to the plains of India through the Himalaya, and Butan: it has, however, a spongy texture, and sells for only one-third of the price of the best rhubarb, and is in quality the Russian, and is found in India.

English rhubarb.—Two kinds of rhubarb are met with in the shops under the name of English rhubarb: one is *dressed*, so as to resemble the Russian rhubarb, is, I believe, the produce of *Rheum*; the other is sometimes called *French* rhubarb, and is said by Steudner and Churchill to be obtained from *Rheum undulatum*, though, in the opinion of some, it is believed to be procured from young roots of the same species as the dressed rhubarb.

Dressed English rhubarb is the produce of *Rheum* in Oxfordshire. It is the most recently observed in the show-bottles of druggists' windows, and is sold in the streets of London (particularly in the Strand and the Poultry) for "Turkey" rhubarb by persons dressed up as Turks. It is in various sized and shaped pieces, which are trimmed and frequently cut so as to represent Russian rhubarb. The pieces are cylindrical or round, and are evidently segments of roots; others are flat. This kind of rhubarb is very light, spongy (especially in the middle of the pieces), and is moist, pasty under the hand, and has a reddish or pinkish colour, as observed in the Asiatic kinds. It has usually a marbled appearance, the streaks are pinkish, parallel, and have a radiated disposition;

and in the centre of some of the larger pieces the texture is soft and woolly, and may be easily indented by the nail. Its taste is astringent and very mucilaginous; it is not at all, or only very slightly, gritty under the teeth; its odour is feeble, and more unpleasant than either the Russian or East Indian kinds. The microscope discovers in it, for the most part, very few crystals of oxalate of lime.

The *common stick English rhubarb* occurs in angular or roundish pieces, of about five or six inches long, and an inch thick. When fractured it presents the radiated appearance, and the red-coloured streaks, of the kind last mentioned. Its taste is astringent, but very mucilaginous; it is not gritty under the teeth; it breaks very short.

English rhubarb is extensively employed by druggists to adulterate the powder of Asiatic rhubarb.

6. *French rhubarb*.—Rhubarb is procured in France from three species of *Rheum*, namely, *Rhaponticum*, *undulatum*, and especially *compactum*. These plants are cultivated in an establishment, at a place called (in consequence) *Rheumpole*, at a little distance from Lorient, in the department of Morbihan. The cultivation of *R. palmatum* has been abandoned.

I am indebted to Professor Guibourt for two varieties of French rhubarb, the one which he terms *flat*, the other *round*: the first is probably the produce of *R. Rhaponticum*, the second of *R. compactum*.

Hornemann has analysed a rhubarb which he terms *R. Rhaponticum*. It was either French or English rhubarb (Geiger says the latter.) The constituents he found were:—

Rhabarbarin (of Pfaff)	10.156
Yellow colouring matter (of Henry)	2.187
Bitter astringent extract	10.416
Oxydized tannin	0.833
Mucilage	3.542
Matter extracted from the fibre by potash ley	40.208
Insoluble residuum	8.542
Lost in the drying of the root . .	6.043
Loss in the analysis	1.447
Rhaponticin	1.043
Starch	14.583
	<hr/>
	100.000

The insoluble residue yielded only one-tenth of its weight of ashes, composed of potash, lime, magnesia, and alumina.

The difference between this and the preceding analyses consists in the presence of rhaponticin and starch, in the absence of oxalic acid, and in the small quantity of ashes yielded by the insoluble residuum.

Chemistry of rhubarb.—Notwithstanding the numerous experiments to which rhubarb has been subjected by some very eminent chemists, our knowledge of its constituents is still exceedingly imperfect. The most important analyses of it which have been made are those of Schrader, Henry, Brande, Hornemann, and Peretti, while some valuable information has been obtained from the researches of Pfaff, Trommsdorf, Henderson, Vaudin, Meissner, Runge, Nani, Caventou, Carpenter, and others.

Some of these chemists have employed the term *rhabarbarin* to indicate a supposed peculiar principle in rhubarb; but unfortunately this term has been applied by different experimenters to different substances, so that great confusion has been thereby produced. Thus the *rhabarbarin* of Pfaff is the alcoholic extract of rhubarb, prepared by digesting the watery extract of rhubarb in rectified spirit of wine. As might be expected from its mode of preparation, it is a mixture of various proximate principles; according to Hornemann, of incrustallizable sugar mixed with a calcareous salt, extractive, resin, semi-resin, and gallic acid. The same authority also tells us that the *rhabarbarin* of Henry (called by some *caphopierite*) consists of a peculiar substance, similar to fat, or oil, (*rheumin*) infusible in boiling water, and which is reddened by an alkali; of resin, and tannin. The *rhabarbarin* of Caventou is a crystallizable yellow colouring matter. These examples (which might be multiplied) are sufficient to show the confusion existing among authors, in the use of this term.

In speaking of the varieties of rhubarb, I have quoted three analyses made by Hornemann. It may not be amiss to subjoin Henry's analysis of China rhubarb.

Peculiar yellow colouring matter (*rhabarbarin*).

Fixed oil.

Supermalate lime.

Gum (small quantity).

Amylaceous matter.

Oxalate of lime (one-third of the weight of the root).

Potash salt (a small quantity).

Sulphate lime (a small quantity).

Oxide of iron.

Lignin.

1. **Odorous matter of rhubarb.**—On what principle does the odour of rhubarb depend? Guibourt says that the taste, colour, and odour, depend on one principle, — namely, the *rhabarbarin* of Henry; which statement, however, is not very probable, since the colour and odour of this root bear no proportion to each other in the different varieties. By many, the presence of a volatile oil has been suspected. In-

deed Bressy, a physician at Arpajon, announced to the *Académie de Médecine*, that he had obtained it, but the commissaries appointed to repeat his experiments were unable to verify his statements.

2. **Colouring matter of rhubarb.**—The colouring matter of rhubarb is extracted both by water and alcohol. Its tint is not precisely the same in all the varieties of rhubarb, being pinker in some than in others. Alkalies (potash, soda, and ammonia) give it a red colour; and on the addition of an acid the original tint is restored, and a precipitate produced. Lime-water reddens and precipitates it. The acids (acetic excepted) precipitate it from its solutions. Various metallic solutions (as the acetate of lead, protochloride of tin, protonitrate of mercury, and the nitrate of silver), also precipitate it. It is partially volatilized by heat: thus, if powdered rhubarb be heated in a capsule over a spirit-lamp, an odorous yellow vapour is obtained, which communicates a red colour to a solution of caustic potash. Mr. Faraday has observed that solutions of boracic acid, and also of the borates made purposely acid, redden turmeric; but do not affect paper stained with rhubarb. Geiger has proposed this as a means of distinguishing rhubarb which had been dyed by means of turmeric; a fraud, I believe, not practised in this country.

3. **Astringent matter of rhubarb.**—In several analyses of rhubarb, tannin (tannic acid) is mentioned as one of the constituents. The chemical evidence of its presence is the action of the ferruginous salts and of gelatine on the infusion of rhubarb. Thus the perchloride and persulphate of iron strike a green colour with the infusion of this root; while a solution of gelatine occasions a copious yellowish precipitate, which is dissolved on the application of heat, or by the addition of an excess of gelatine. These effects, however, have been said to depend on the action of the tests just mentioned, on the *rhabarbarin* of Henry; but that tannic acid is really present seems to be highly probable from the astringent taste of the root, and from the large quantity of this acid found in other plants of this family, as in *Coccoloba uvifera*, and *Polygonum Bistorta*. Moreover, the vegetable alkaline salts (as sulphate of quinia) produce a precipitate with the infusion of rhubarb, an effect which they also produce with solutions of tannic acid. If, indeed, rhubarb do not contain this acid, we have yet to learn the real characteristics of tannin. The red veins are the seat of this presumed acid, as is shewn by brushing the cut surface of a piece of rhubarb with a weak solution of iron: the change of colour occurs at these parts only.

4. Purgative principle of rhubarb.—The purgative property of rhubarb has been successively ascribed to extractive, to resin, to the colouring matter, and to a peculiar vegetable alkali. Further evidence, however, is required before we can admit any one of these statements. The phenomena of the action of iodine on an infusion of rhubarb, presently to be mentioned, are certainly in favour of the presence of a basic principle. Whatever may be its precise chemical nature, it seems, as met with in rhubarb, to be soluble in water, alcohol, and æther, since all these liquids acquire purgative properties by digestion with this root.

5. Fixed oil.—A bland fixed oil, in very small quantity, is said to exist in rhubarb. It becomes rancid by heat, and is soluble in both alcohol and æther.

6. Gum—Starch—Sugar.—Gum, starch, and, according to Meissner, sugar, exist in rhubarb. If a solution of iodine, or of ioduretted iodide of potassium, be added to a decoction of Russian, East Indian, or Dutch-trimmed rhubarb, a greenish-blue colour is immediately produced. After a little time this colour disappears, the original tint of the decoction returning; and no free iodine can be detected by the addition of starch. Hence it would appear that the iodine must enter into some new combination with a basic substance, forming probably an iodide, and perhaps also an iodate. This is apparently proved by the fact, that the addition of nitric acid restores the greenish-blue tinge of the solution.

If a solution of iodine be added to an infusion of English rhubarb, an intense blue iodide of starch is formed, which does not totally disappear by standing; so that it would appear there is less of the basic substance in this variety than in the Russian and Chinese kinds.

Geiger says that the tincture of iodine produces, with the powder of Russian rhubarb a dark green colour; with that of Chinese rhubarb a brown (not a dark green, except in a few instances); with that of English rhubarb a dark-green, as in the Russian kind; with that of French rhubarb a blue. I have several times repeated these experiments, but have never been able to obtain the above-mentioned distinction between the Russian and Chinese kinds.

7. Oxalate of lime.—The large quantity of oxalate of lime found in Asiatic rhubarb is a remarkable circumstance. It exists in the white veins of the root, and, as already mentioned, according to Raspail, is formed in the interstices of the elongated cells. The crystals of this salt may be recognised by the grittiness of rhubarb when chewed, by a microscopic examination of boiled films of the root, or by rub-

bing these films between two plates of glass. By incinerating rhubarb root the oxalate is decomposed, and converted into carbonate of lime. Chinese is said to contain more of the oxalate than the East Indian rhubarb, though the quantity varies in different specimens of each kind. For the most part English rhubarb contains but little of this salt, though I have occasionally met with specimens possessing it in abundance. In the laboratory we are unable to produce this salt in a crystallized form; in plants, however, it is very common in this state. Its crystallization is here probably produced by the slowness with which its constituents are allowed to come together.

I do not think it necessary to individualize the other constituents of rhubarb.

Physiological effects: (a.) *In small doses.*—Taken in small doses, as from four to eight grains, rhubarb acts as an astringent tonic, its action as such being principally or wholly confined to the digestive organs: thus in debilitated conditions of these parts it promotes the appetite, assists the digestive process, and improves the condition of the mucous secretions. (b.) *In larger doses,* as from a scruple to a drachm, it operates as a purgative, slowly and mildly, though sometimes with a little griping. It never inflames the mucous membrane of the alimentary canal, as jalap, scammony, colocynth, and other drastic cathartics do. Constipation usually follows its purgative effect, and which is referred to its astringent principle; but the same effect is commonly observed after the employment of other purgatives. In febrile complaints and inflammatory diseases (as peripneumony), it is said to accelerate the pulse, and increase the heat of the body, and, therefore, in such cases, is considered objectionable.

Modus operandi.—The colouring and purgative principles of rhubarb become absorbed. Tiedemann and Gmelin found the colouring matter in the blood of the mesenteric, splenic, and portal veins of dogs, to whom this root had been administered. In the urine the colouring matter of rhubarb may frequently be detected by the high tint of this secretion, and by the red colour produced by the addition of potash, which would thereby distinguish the colouring matter of rhubarb from that of the bile. It does not appear, however, to affect the quantity of urine secreted.

That the purgative principle of rhubarb is also absorbed, is shewn by the purgative quality of the milk of nurses to whom this root has been administered.

Rhubarb has for a very long period been considered to possess a specific influence over the liver, to promote the secretion of bile, and to be useful in jaundice. Dr.

Cullen says, he cannot find any foundation for this opinion either in theory or practice. It seems to have arisen entirely from the absurd doctrine of signatures.

Observation does not support the opinion at one time entertained, that rhubarb acted as a tonic to the system generally.

Use.—1. As a purgative. As an ordinary purgative, rhubarb is considered objectionable, on account of the constipation which follows its purgative effect. It is well adapted, however, to those forms of diarrhoea in which some irritating matter is still contained in the bowels: it first evacuates this, and afterwards acts as an astringent. Dr. Cullen has justly observed, that "in many cases of diarrhoea no further evacuation than what is occasioned by the disease is necessary or proper, and, therefore, the vulgar practice of employing rhubarb in every case of this disease, appears to me to be very injudicious."

As an infant's purgative, rhubarb is deservedly celebrated. It is well adapted to a variety of complaints, but is especially serviceable in mesenteric affections, and in those cases accompanied by an enlarged belly.

Sulphate of potash is a very useful adjunct to rhubarb in cases of diarrhoea in adults. For children, rhubarb is usually combined with magnesia or chalk; and when the object is to promote the secretions generally and produce an alterative effect, the *hydrargyrum cum creta* is frequently conjoined.

2. As a stomachic and tonic. In those forms of dyspepsia depending on a debilitated condition of the digestive organs, rhubarb in small doses is given with great benefit.

3. As a vermifuge. It has also been employed against worms.

4. External use. Alibert has used rhubarb by way of friction, with saliva or with lard, on the abdomen. Home used it to stimulate indolent ulcers.

Rumex Acetosa.

As the leaves of *Rumex Acetosa* are officinal substances, we must not pass over this plant, though it is very rarely employed in medicine.

Common sorrel is a well-known indigenous vegetable, belonging to class *Heandria*, order *Trigynia* of the Linnean arrangement. Its flowers are dioecious, and are composed of a six-parted calyx, the sepals being permanent and tuberculated; six stamina; three reflexed styles, with three cut stigmas. The fruit is a nut, with three sharp angles: the embryo is on one side; the radicle superior. The leaves are oblong and arrow shaped.

Sorrel leaves have an agreeable acid, slightly astringent taste, and contain the bin-oxalate of potash, tartaric acid, mucilage,

and secula: moreover, the green colour which the leaves produce with effusions of iron, shows the presence of tannic acid.

In some countries sorrel is eaten as a salad. It acts as a refrigerant and diuretic. A decoction of the leaves may be employed in the form of a whey, as a cooling and pleasant drink in febrile and inflammatory diseases. Laugier has suggested that the use of aliments containing oxalic acid, as sorrel, may, under some circumstances, give rise to the production of calculi of oxalate of lime.

Polygonum Bistorta.

Bistort (*Bistorta*,—*bis torta* twice twisted or wreathed) is an indigenous plant, belonging to the class *Octandria*, order *Trigynia*.

Botany.—It is about a foot and a half high. Its root is large, tortuous, and very astringent; its stem is simple, bearing one cluster; the leaves are ovate, waved—the radicle ones tapering into a footstalk; flowers arranged in spiked clusters, and composed of a monophyllous, divided petaloid stigma; eight stamina, and three styles. The fruit is a triquetrous nut.

Properties.—The root is twice bent on itself; is rugous and brown externally, reddish internally, almost inodorous, and of an austere and strongly astringent taste. It is very rich in tannic acid, as is shown by the blueish-black precipitate with the ferruginous salts, and the tannate of gelatine formed with a solution of isinglass. This root contains also a considerable quantity of starch, and, according to Schcele, oxalate of lime.

Effects.—Its local action is that of a powerful astringent, depending on the tannic acid; its remote action is that of a tonic. The quantity of starch it contains renders it nutritive; and in Siberia it is employed as an aliment after having been roasted.

A decoction of bistort may be employed as an injection in leucorrhœa and gleet; as a gargle in spongy gums and relaxed sore throat; and as a lotion to ulcers attended with excessive discharge.

Internally it has been employed, combined with gentian, in intermittents. It may also be used in passive hæmorrhages and diarrhoea.

Coccoloba uvifera.

The *sea-side grape* is a middle-sized tree, growing in the West Indies, and belonging to the class *Octandria*, order *Monogynia* in the Linnean arrangement. Its bark is of an astringent nature, and from it is said to be obtained an extract at one time introduced into medicine as *Jamaica kino*.

ON THE
THEORY AND PRACTICE OF
PERCUSSION

AS A

MODE OF DIAGNOSIS.

—

Editor of the Medical Gazette.

A number of your journal there is a communication from my friend Dr. King, describing the results of experiments on percussion which appears to be opposed to my views on the subject, as they are reported in your paper, from a communication I read at the time since to the Westminster Medical Society. I have reason to believe that my ingenious friend will not differ with me when my views are placed before him in a clearer manner than that of the report in question. As I venture to suppose that my views will not be unacceptable to some of your readers, I solicit a few of your issues through the medium of communication. This contains the substance of the remarks which I made to the Westminster Medical Society, and in a note I will advert to the objections of your paper.—I am, sir,

Your obedient servant,

CHAS. J. B. WILLIAMS.

1837.

Class of physical signs which are obtained by attending to the character of the sound which different parts of the chest yield on being struck, might be brought under the first consideration, so simple in nature, and so obvious in their production, as to need very little attention to enable us to understand them, and but slight experience to enable us to practise them. But when a student first applies this knowledge to the chest,—when he tries to elicit from the chest and abdomen the respective sounds which are described to characterize different regions,—he is generally disappointed with the obscurity of the results. He sees the experienced auscultator exhibit striking contrasts of results in his own attempts to elicit sounds as obvious and unequivocal.

cal. But he soon finds that there is much more in the manner of using percussion than he has been led to expect. It is a long lesson of experience, and there are very few who have patience and perseverance to learn it. The majority of those who do attempt it are content to go only so far as the results seem obvious and easily obtained, and leave a great number of cases but little elucidated by this method of diagnosis.

But the difficulties of percussion, and the anomalies of its results, do not occur only to students in the practice. Puzzling and deceptive cases sometimes present themselves to the most experienced; and Laennec himself was constrained to confess that he sometimes met with chests which sounded badly, although the parietes were thin, the respiration perfect,—and he could not assign a cause for the defective sound. The deficient resonance of the chest in certain cases of spasmodic asthma, was also to him a matter of obscurity.

The great aid which M. Piorry brought to the practice of percussion, in employing a *pleximeter* or *percussion-plate*, diminishes greatly the difficulties of percussion, by affording a uniformity and firmness of surface, which the natural parietes of the chest do not present; and this mediate percussion with a pleximeter, or what generally answers as well, with one or more fingers of the left hand, is the method now usually adopted. But even this improved method is not without its difficulties; and I continually find not only students, but practitioners experienced in the art, obtain different results on percussing the same subjects; nay, I have seen a very skilful auscultator perplexed at finding the same spot of the chest at one moment give a dull sound, and at the next a pretty clear one, notwithstanding the usual precautions were taken to obtain a uniformity of result. The same difficulties having frequently occurred to myself, I was some time ago led to study the acoustic principle of percussion more fully than had hitherto been done; and I now proceed to state some of the views and practical conclusions to which this study has led me.

The deep or hollow sound which the surface of a healthy chest yields on being struck, has been in a general way vaguely referred to the air contained in the lungs within it. Laennec con-

tented himself with this view, without tracing more accurately the nature of the process. Piorry and Forbes, who have written since more fully on the subject of percussion, give rather the parallel phenomena of inanimate objects, than any exact analysis of the sounds in question. The latter writer, where he is more precise, seems to imply that the vibrations of the air diffused through the lung produce the sound so remarkable for its hollowness, and that liquid or solid effusions prevent this air from receiving these vibrations. We must complete the elements of this view before we can test its accordance with the phenomena observed.

It is well known that different bodies yield different sounds when struck; and it is supposed that as hollow bodies yield the loudest sound, this must proceed from the vibrations of the air within them. Solid bodies, and those containing liquids, on the other hand, give dull sounds, from being destitute of air. So, it is supposed, the chest will yield a sound loud in proportion to the quantity of air contained within it, this air being the most sonorous body. Now this view, which, as far as vague expressions can be interpreted, is the one generally received, I conceive to be opposed by the following considerations.

1. If the sound obtained on striking the chest depended on the vibrations of the air within, it should be deepened in tone by increasing the volume of that air, and raised by diminishing it; just as the note given by any hollow vessel when struck will be deep in proportion to the size of its interior*. Now changing the quantity of air in the chest by acts of respiration does not in this manner alter the sound of percussion: slight changes produce no difference; and a very full inspiration, instead of deepening the sound, actually raises its tone in a very perceptible degree.

2. If the sound of striking the chest originated in the air within it, it should be greatly changed by closing the glottis; for the sound given by a hollow vessel, or India rubber bottle with its mouth closed, is totally different from that which it yields with its mouth open. Now, provided no respiratory

effort be at the same time made, striking the chest gives the same sound whether the glottis be shut or open.

3. The sonorous vibrations of air contained in cavities may be of two kinds. One depends on any impulse communicated to the mouth of the cavity, and resisted by the body of air within, acting in the manner of a bottle, or of a tube closed at one end. This requires that the cavity should communicate with the external air, which we have seen is not necessary to the pectoral sound. The second kind of sound produced in air-filled cavities, is that resulting from the successive reflections of any sonorous impulse from side to side of the cavity; which reflections becoming regular vibrations, constitute a sound of a determinate character. This constitutes the prolonged reverberations heard in empty casks, the tinkling echo of the interior of bottles, cups, &c., the phenomena of metallic tinkling and amphoric resonance heard in various smooth air-filled cavities of the animal body*. But this cannot constitute the sound of pectoral percussion; for in a cavity of the size of the chest, instead of being drum-like, it would be tinkling, as it actually is in pneumo-thorax. Further, the pulmonary tissue, as it prevents the transmission of the voice from the bronchi to the surface, except at points where these are quite superficial, so much more completely will it prevent the transmission and reflection of sonorous vibrations to-and-fro, across the whole interior of the chest.

The last argument will be, to those who are really familiar with the laws of acoustics, quite conclusive against the notion that the air in the chest is the seat of the sound elicited by percussion. There is, in truth, no air-filled cavity, but a heterogeneous sponge, eminently calculated to arrest the vibrations of air, and which does more or less completely intercept those of the voice from being transmitted to the parietes of the chest. To consider the air in the lungs to be the seat of sound of percussion of the chest, is about as reasonable as to suppose that

* A convenient object for illustrating this is an India rubber bottle: when its cavity is diminished by compressing its sides, the note which it yields will be raised in proportion.

* This tinkling resonance is interesting, as it gives rise to several instructive phenomena of auscultation. It may be illustrated by holding the mouth of an India rubber bottle to the ear, and striking the side of the bottle: each stroke is attended, or rather followed, by a metallic clink.—See Pathology and Diagnosis of Diseases of the Chest, 3d edit. p. 115.

a flute or a pan-pipe would yield its tones when filled with wool.

It being thus proved that the air in the lungs is not the seat of the sound elicited on striking the chest, we are driven to the supposition that the solids are the essential seat of the vibrations, and that they derive the character of their vibrations from their own degree of tension, and from the nature of the resistance offered to them by the adjoining, and especially the subjacent, parts. This is the view which I have for some years adopted, and the following remarks will, I trust, illustrate its correspondence with the phenomena, and show how it will materially aid us in the practice of percussion.

The bony frame of the thorax, bound together by elastic cartilages and ligaments, its interstices filled up by the intercostal muscles, and its whole interior lined tensely by the costal pleura, constitutes an elastic box or drum, any part of which may be readily thrown into sonorous vibrations by an impulse applied to its surface. There are, however, superimposed on this frame-work, at certain parts, various muscles, the scapulæ and the mammary glands; and the integuments, with their fatty and cellular tissues, cover the whole exterior. The effect of these is to deaden in various degrees the sound produced on percussion; and they do this both by intercepting and deadening the stroke, and also by their loose mass muffling the vibrations. It is by bringing these soft inequalities into a firm equally tense surface, on which percussion can be effectually practised, that M. Piorry's pleximeter proves chiefly useful; and by means of it, or of the fingers of the left hand applied for the same end, any part of the walls of the chest may be brought to such a degree of tension, as when struck to vibrate *according to the nature of the substance which lies beneath it*. If, for example, that substance is the air-filled tissue of the lung, it offers such a yielding but elastic resistance as gives the part struck a freedom and length of vibration; the sound elicited is therefore clear and deep-toned. If the substance under the point struck is solid and contains no air, as the liver, the vibrations being abruptly resisted, the sound has no depth or continuance, but is dull or *mat*. If a body of liquid be underneath, this will

also check the vibrations, so that the sound yielded will be merely a short dead *tap**. In pneumo-thorax, where the chest contains air instead of lung, the parietes approach more nearly to the condition of the parchment of a drum, and give, when struck, a sound unusually clear. In this sound we may often perceive a hollow or metallic character ("stomacal" of Piorry), which is not present in the pulmonary sound. This character truly *does* depend on the vibrations of the *air* contained in the cavity, which here presents a condition that we have proved to be wanting in the pulmonary tissue. The same character will be found in the sound obtained on percussion of the region of the stomach, cœcum, and other parts of the intestines, which also present the condition of a cavity in which air vibrates, and adds its note to that of the walls percussed.

* Dr. Clendinning will perceive that this view is in perfect accordance with the results of his experiments. The sound obtained on directly striking a piece of lung or of liver, must partake of that character which that piece of lung or liver communicates to the vibrations of the thoracic walls: the lung will yield a sound by the vibration of its membranes distended with air; but as the distension is imperfect unless some pressure be used, the sound will be weak and short in comparison with that yielded by the walls of the chest exactly opposed to the entire air-filled lung. So likewise the liver, as it renders short and abrupt the vibrations of the walls of the chest in contact with it, will, when directly struck, yield its own dead sound, consisting of the same unrepenting vibrations. My worthy friend seems to imply that, according to my view, no particular sound should be yielded by the naked lung or liver; but if this were a deduction from it, how can I suppose these organs to change the vibrations of the walls of the chest? It is by their elasticity that bodies vibrate; and this motion, if sufficiently rapid, is propagated to our ears as sound. It is this same quality of elasticity, which, in different bodies placed in contact, modifies the motions, and consequently the sounds, of any one of these bodies. Sound is resisted motion, and the nature of the sound will depend on the resistance given to the motion. The same property which modifies sound of adjoining bodies, if it be capable of producing any sound, will produce sound of the quality which it communicates to the sound of the adjoining bodies. The naked lungs, therefore, and the liver, if they are capable of giving any sound at all, must give that character of sound which they communicate to the stroke on the walls of the chest. This explanation may seem unnecessarily minute; and it may suffice to most readers that I remind Dr. Clendinning that I do not deny to the solids the power to give sound on percussion, but I deny it to the air in the lungs, because I find that this air is in a condition in which it cannot, according to well-established laws, produce such a sound as that resulting from percussion on the chest. The air, by modifying the condition of the solids, alters their sounds, but by percussion gives no sound of its own.

We now see that the air-filled structure of the lung is not the only condition requisite to render the pectoral resonance deep and clear; a certain elastic tension of the walls of the chest, at the point struck, is also indispensable, inasmuch as these walls are the essential seat of the sound. The anomalous cases, adverted to by Laennec, of badly-sounding chests, where the lungs are healthy, are referable to a defect of this latter condition—elasticity of the walls. In a few cases a peculiar laxity of these walls causes the defect of resonance; but the commoner cause is a drawing in of these walls from certain conditions of the interior. Contractile pleurisies, by leaving adhesions, the constant tendency of which is to shorten, draw in the parietes of the chest, so as to destroy that equality of tension which fits them for vibration; and consequently chests thus affected rarely recover their original resonance. Another cause, which is rarer, and may be only temporary, is spasmodic asthma. In this affection the bronchial muscles are permanently contracted, so as to diminish the size of the whole lung, and the walls of the chest are kept under the constant influence of unequal atmospheric pressure, either from without or from within, which much impairs the freedom of their vibrations. In all these cases mediate percussion on a pleximeter, or on the fingers pressed firmly to the chest, will often obtain a pretty clear sound; and this it obviously effects by the pressure exceeding the force drawing from within, and by thus restoring in a measure the balance of tension.

There is another cause of defective resonance that well illustrates the subject before us. In advanced stages of phthisis, where a large portion of a lung is excavated, and a thin layer of pulmonary tissue on the pleura only separates the cavity from the parietes, this portion of the chest will sound dull, although there is actually more air in it than exists in the healthy state. The thin layer of pulmonary tissue falling loose and flaccid on the parietes, acts as a damper upon them, checking and muffling their vibrations, just as a handkerchief on a violin string will stifle its notes.

We can now understand why, on a full inspiration, the sound on percussion

is higher in tone than usual: the expanded parietes are then brought to a greater degree of tension, vibrate more quickly, and therefore yield a higher note. A forcible expiration has a similar effect, with this addition, that there is a diminution of that elastic material within, which resists like a spring the stroke of percussion on the exterior. Emphysema of the lung, when it is sufficient to give to parts of the chest that rounded convex form which is so remarkable in the extensive degrees of this affection, has an effect on the percussory resonance similar to that of a full inspiration; it renders the sound louder, but higher in key, the distended lung resisting with a stronger spring than usual the impulse of the parietes.

But the most important application of this view is to guide us in regard to the mode in which percussion is to be performed, in order to make its results bespeak the condition of the internal parts. The first precaution to be observed is, that the spot percussed shall be in such a state of tension that it may vibrate; and if this be not the natural condition of the part, a degree of pressure, with the finger or pleximeter, will give this condition to it. With regard to the stroke of percussion, I need not repeat the usual rules, that it should be made perpendicularly to the surface, and on corresponding points on comparing the two sides, &c.; but there is one particular in the practice of percussion that deserves more notice than it has received; I mean *the force of the stroke*.

According as the chest is struck gently or forcibly, so will the impulse be confined to the superficial parts, or it will reach those that are more deeply seated; and as the vibrations will be determined by the nature of the resistance which the impulse meets as far as it reaches, so will the character of the sound vary with the force of the stroke, if the superficial and the deep-seated parts differ in their densities. A want of the knowledge of this fact has been a fertile source of practical error among auscultators, especially the less experienced; and although, even when aware of it, we have still the difficulty of estimating accurately the degree of force used, and of judging between slight differences of sound, yet the following observations will, I think, shew

that attention to this matter will often facilitate the employment of percussion, and increase the number of its useful results.

In all the upper parts of the chest, the lungs in health occupy so great a depth, that the sound elicited by percussion will be of the character called pulmonary, whether the force of percussion be great or small. In the posterior regions, of course, strong mediate percussion will give the best sound, inasmuch as it overcomes the deadening effect of the thick layer of muscles in that region. But in the inferior parts, the heart and the abdominal viscera that rise in the middle of the chest, beneath the vault of the diaphragm, reduce the thickness of the pulmonary tissue in various degrees. On the right side of the chest strong percussion, carried from above downwards, generally detects a diminution of the sound below the fourth rib, which indicates the common height of the arch of the diaphragm and liver in the central portions of the chest*. Below this the sound becomes more and more dull; and in this gradual *shading off* of the sound, it is extremely difficult to define where the pulmonary sound ends, and the pure hepatic sound begins. Very gentle percussion will do this, and will distinctly elicit a pulmonary sound three or four ribs lower, down to the very thin margins of the lower lobes†. In the region of the heart, also, where the thin margins of the lung during full inspiration overlap the organ, gentle percussion will generally indicate how far the thinnest portion of lung reaches, where stronger percussion announces the resistance of the deeper seated solid. It is not equally easy to define the limits of the lung, where it overlaps the stomach or colon; for although deeper seated, the tympanitic elasticity of these organs makes

them susceptible of vibration from a very slight impulse. Still a very perceptible character of pulmonary sound may be elicited by gentle percussion on these regions, which differs from the simple tympanitic resonance of an air-filled sac.

* Such being the properties of the healthy chest as tested by these modified degrees of percussion, we may now see how disease will change them.

Slight effusions, whether pleuritic or hydropic, occupying the lower parts of the chest, separate the lung from its close contact with the walls of the chest, without displacing it altogether. In these cases the relations of the lower parts of the chest to percussion will be the reverse of what it is naturally: the stroke of gentle percussion will not pass through the thin layer of serum, and its sound will be therefore dull; while stronger percussion will carry its impulse to the remaining pulmonary tissue, and its sound will therefore return a certain degree of pulmonary character. Even in extensive effusions into the pleura, a small portion of pulmonary tissue, into which the air can still enter, produces a perceptible difference in the sound elicited by strong percussion, although the impulse has to pass through some inches of liquid. In practising percussion on the mediastinal confines of a pleuritic effusion, the stroke should be gentle, and perpendicular to the surface; for forcible percussion, especially if it be at all oblique, will often borrow an elastic resonance from the opposite side*.

* That the diaphragm rises thus high in the chest is a fact described indeed by anatomists, but little attended to by physicians. My attention has been directed to this matter by my friend Dr. Edwin Harrison, who has taken great pains to investigate it.

† The best mode of making this gentle percussion is by *flipping* on a finger of the left hand pretty firmly applied to the surface. The slight abrupt impulse thus given does not reach the deeper seated parts, and yet gives a sound loud enough to be very characteristic of those which are more superficial. This mode is very useful in exploring the state of the abdomen. If it be done with care, the tenderest parts may be percussed in this way without giving any uneasiness.

* I have been for some time acquainted with the fact, that the resonance of a portion of lung could be detected through a considerable stratum of liquid; but the experiments of Dr. Clendinning and Dr. Edwin Harrison have proved this to take place to a greater extent than I was aware of. The explanation, however, is easy, in the view which I have advanced. The impulse is propagated without difficulty through a uniform mass of liquid, and if it reaches a portion of air-filled lung, whether that be on the same or on the opposite side of the pleura, that lung will affect the nature of the vibration which the impulse produces, and the sound of the stroke on the surface will be more or less pulmonary in character. Observe, the sound *on the surface* partakes of the pulmonary character, although the lung is several inches distant: no sound is heard *in the lung*, but at a remote part of the parietes, where the stroke is applied. This is another fact illustrating the position which I have advanced, that the sound which we hear on percussion of the chest is essentially in the parietes, although the character of that sound is communicated to these

Pneumonia, or pulmonary apoplexy, situated in the margins of the lower lobes, will remove the distinction given in the natural state by degrees of force in percussion; and if the disease be, as it frequently is, circumscribed, that gradual shading off of the sound on strong percussion, which I have described as perceptible in the natural condition of these parts, will be absent. In these cases, therefore, gentle as well as strong percussion produces a dull sound; and by tracing the outlines of this dullness, we shall generally find its shape to differ from that resulting from a liquid effusion.

Emphysema in the same situation will have a contrary effect, and will make it easier than usual to define by gentle percussion the limits of the lower lobes. If the emphysema be excessive, besides an unusual resonance, the sound will be higher in key than usual.

In pneumo-thorax the *shading off* ceases, the sound having every where a tympanitic character; and if, as is usually the case, liquid effusion be also present, gentle percussion will shew with great precision the level of the liquid.

In the early stages of phthisis, while the indurations are still of small extent, gentle mediate percussion will be the most likely means of detecting them. As tubercles most usually infest the summits of the lungs near the surface, and often produce pleuritic adhesions at those points, they will generally affect the sound of *gentle* percussion on the clavicles, or on the space below them; whereas forcible strokes would overcome the resistance of these small superficial deposits, and give sounds not to be distinguished from those of the healthy chest. In this very obscure and difficult point of diagnosis another rule with regard to percussion deserves attention. Aggregated tubercles can be most easily detected by gentle percussion limited to the spot. Military granulations scattered through the tissue are more likely to affect the vibrations, by

the combined resistance of many; and the stroke should be therefore applied to a larger surface. Gentle percussion on a single finger, or a small pleximeter, will be the most likely to afford indications of the presence of the former; while scattered granulations may be better detected by mediate or immediate percussion by the fingers of the flat hand applied over some inches of surface. In examining a doubtful case, both these methods must be used at different periods of the respiratory movements; and I can state, from some experience, that attention to these particulars will leave many fewer of the cases of incipient phthisis in that negative uncertainty that has been the reproach of even the present improved state of diagnosis.

It is unnecessary to dwell on other applications of these principles, to indicate how percussion in its modifications may be rendered an easier and surer test of disease: as, for instance, flat percussion, in humid bronchitis, first stage of pneumonia, and œdema of the lungs, giving some mark of the extent of the effusion; strong percussion giving an outline of an enlarged heart, or of any deep seated condensation; gentle mediate percussion indicating with exactitude the state of the more superficial contents of the chest and abdomen; and so forth. But having called attention to the principle of percussion, and having, as I trust, made that principle intelligible in the more important of its applications, it remains for an accurate knowledge of pathology, and the opportunities of a varied experience, to make it more useful than any further description of mine could render it.

ON THE

SENSE OF TASTE.

To the Editor of the Medical Gazette.

SIR,

I CERTAINLY had no intention to wound the feelings of Dr. Alcock in my communication which appeared in the GAZETTE for December 17th, commenting upon the conclusions at which he had

parietes by the subjacent parts. When lung lies under them, the sound is what is called pulmonary; when liver, it is dull; but when both liver and lung, the sound is not double, as if proceeding from both as sources, but between both, as if consisting of vibrations which result from the elasticities of both simultaneously influencing the vibrations of the walls. So it is, also, when a layer of liquid adds its effect.

arrived relative to the nervous connexions of the sense of taste; and I trust that much of the soreness of spirit which his reply to my remarks evinces, will be found to have originated mainly in the misapprehension of part of my meaning, to which I may further allude in the sequel.

Dr. Alcock ranges under three heads what he is pleased to call my imputations against him. I will follow the example which he has set me, and discuss the topics of difference between us under three distinct heads. If any accusation of want of candour have been brought by me against Dr. Alcock, it rests upon these grounds—that he, in his paper, as published at length in the *Dublin Journal*, prefatory to any account of the experiments which he had performed, offers a variety of considerations, drawn from various sources, to show the independent character of the sense of taste, and yet omits a reference to cases demonstrating the fact. But further, it appears to me, and may appear to others, that the first case published by me, in connexion with this subject, leads to inferences totally at variance with those of Dr. Alcock. In this way: the case of Mrs. Williams, to which I allude, furnishes an instance of complete paralysis of the *sentient* portion of the fifth nerve on one side, and yet the patient *tasted perfectly* on the corresponding half of the tongue. Dr. Alcock artificially induced paralysis of the tongue in a dog, by division of the lingual branch of the same nerve, and discovered that a very material diminution of the sense of taste was the consequence. Now I do not say that here are contradictory results, because the data are not precisely similar; but it does appear to me that the difficulty should have been fairly met by Dr. Alcock, inasmuch as he was evidently not unacquainted with my papers upon the subject. It is true, as stated by him, that whilst my own data were pathological, his were purely physiological; but nevertheless, in deducing a general inference, neither class of phenomena can be so insulated as to exclude all communication with the other, more especially when any discordance appears to exist between the two; for in all such cases the appearance of discordance must be made to vanish, or the conclusion is inevitable that error exists somewhere. On these grounds,

then, do I regret that, in assuming to have determined the question relative to the nervous relations of the sense of taste, Dr. Alcock had not the candour to refer to what had been previously offered to the profession, in apparent opposition, by myself. But, says Dr. Alcock, the cases which I have published “require to be confirmed and put beyond doubt.” In regard to this, I have only to observe, that the experiments upon the first case have several times been repeated, with uniform results,—that, as stated by me in the *MEDICAL GAZETTE*, the second case was furnished by Mr. Ker, before whom and Mr. Walker the particular examination was made,—and that I had the perfect concurrence of those gentlemen in the accuracy of the investigation and of the results. And in further confirmation, I may refer to the corroborative instance furnished by your correspondent, Mr. Bishop, and published in the *MEDICAL GAZETTE* for February 6th, 1836, who, towards the conclusion of a paper written in *opposition to my own reasoning* on this subject, most honourably and faithfully observes—“A case in illustration of this theory has been brought to my notice by Mr. Roberts, in a woman, aged about 45 years, who has nearly lost the common sensibility of the whole right side of the face, including the eye, nostril, and tongue, which latter part, however, retains a slight perception of touch, but the taste on that side is entirely abolished, so that neither vinegar, salt, nor ordinary aliments, produce the slightest impression,—a circumstance exactly agreeing with the experiments of Mr. Noble.”

When Dr. Alcock states that “every tyro in physiology knows that, according to the popular opinion, taste is as distinct a sense as any other,” and that the doctrine, that taste is a special sensation, was received of physiologists before he was born, I am anxious that we should not misunderstand each other in the employment of terms. To avoid risk of being myself misconceived, I will repeat that the object which I have always stated myself to have had in view in what I have written upon this subject, has been to determine that taste maintains as special and independent a character as the rest of the senses; and, accordingly, that, as in the case of sight, hearing, and smell, we must look for a *special* nervous pro-

vision. And the evidence which I have offered in support of this view is, in my own judgment, of the most satisfactory nature. Nor is mine a novel mode of deducing such an inference. The fact of feeling and voluntary motion not being impaired or annihilated simultaneously, first led to the conclusion that there were distinct nerves for these functions. And so far back as the days of the celebrated Alexandrian School, founded by the Ptolemies, this was maintained on such grounds, and was even taught by Erasistratus. From precisely similar data, from pathological facts, have I contended for distinctness of nerve coincidently with speciality of function in the case of taste and common sensation. Will Dr. Alcock contend that this is a doctrine known to every tyro in physiology, or that it has descended to us from our ancestors? I think he will not. Will he, then, have the kindness to state, in terms equally definite and precise, what he means by a special sensation, and how he considers that taste is proved to be such by his own experiments.

Dr. Alcock asks for my meaning when I state that it is a recognised principle in the physiology of the nervous system, "that a simple and special function must have but one simple nerve for its manifestation." In explanation, I shall be glad to adopt the "strict interpretation of the principle," as furnished by himself—"that the manifestation of a simple and special function *can* have but one simple nerve." But, he goes on to inquire, "where among our senses do we find the confirmation of this?" In reference to this matter, I join issue with Dr. Alcock upon a plain, undoubted, matter of fact; and, in opposition to him, contend that we have such confirmation in *all* the senses,—that the optic nerve is the sole and special medium of vision,—that the olfactory nerve is the special and exclusive medium of smell,—and the auditory nerve that of hearing. Because I have appealed to the authority of Sir C. Bell, Dr. Alcock calls in the aid of Magendie. Now, in reference to the importance of this latter as an authority, I have to observe that Magendie, as an experimenter, must be universally allowed to rank as one of our "leading authorities;" but, as a propounder of principles, few, I am sure, will bow to his name. It will not surely be main-

tained that the one talent necessarily implies the other,—that it is not one thing to hew and carve the stone, and another to arrange and raise with architectural design. If any one should feel disposed to award to Magendie the peculiar genius of Bell, let him just refer to the section on this very subject, on the senses, in the work of the former physiologist, where, if I mistake not, he will find any thing rather than precision of thought and consistency of statement. But Dr. Alcock appeals to direct facts in support of the consistency of his own inferences, and asserts that "smell is not perfect without the fifth nerve." That a material derangement of the function of the fifth nerve may, in many cases, sympathetically affect the function of the first, I feel no doubt; but that impressions of odour are communicated to the brain by any other medium than the olfactory nerve, I entirely deny, and with that positiveness with which Dr. Alcock asserts the contrary. Dr. Alcock next affirms that "amaurosis is the consequence of an injury of the fifth nerve." Is he serious? Why, examples are on record of even total destruction of the fifth nerve, without any such results; and, not to pursue this matter with unnecessary prolixity, I will refer Dr. Alcock to one instance. In the *MEDICAL GAZETTE*, for December 12, 1835, there is a paper by Mr. Bishop, detailing the history of a case of facial paralysis, wherein a post-mortem examination was carefully made by him, in the presence of Dr. Roget and Mr. Robert Wade; and in his account the following observations occur:—"In the case just related the whole of the fifth nerve was completely destroyed, whilst both the eye and nostril of that side had lost their sense of touch, *retaining the faculties of vision and smell.*" This case during life had been seen by Dr. J. Johnson, Dr. Roget, Sir Benjamin Brodie, and Sir C. Bell. Dr. Alcock next observes that, in one of my own cases of facial paralysis, the hearing was imperfect. Well, what of that;—therein is coincidence, but where is the consequence? Again, Dr. Alcock asks how I reconcile with the "recognized principle" my own conclusion relative to the function of the chorda tympani, and other branches of Meckel's ganglion, which he states to belong to the fifth. In answer to this, I can assure Dr. Alcock that I

have drawn no conclusion at all upon the subject, and that far from disliking the term "suggestion," as he appears to think, it is what alone I can recognise as applying to myself. I have never done more than *suggested* a function for these nerves. But are they branches of the fifth, in the ordinary acceptation of the term? Certainly not, but branches of the spheno-palatine ganglion; communicating with the fifth, it is true, but not being derived from it. As well may it be said that the solar plexus of nerves are branches of the par vagum. If I understand Dr. Alcock aright, he means to affirm, in confirmation of his own views, that although the glosso-pharyngeal nerve is simple in its origin, its function must be compound, because of its distribution. This, I apprehend, is a mode of proof which few will deem admissible. When reference is made by Dr. Alcock to Magendie's notions regarding the multifarious operations of the fifth nerve, he surely does not think that he thereby enhances the importance of this physiologist as a "leading authority" in the promulgation of "principles." With respect to the opinion of Dumeril and Serres on the nerve of smell in the dolphin, I refer Dr. Alcock to Bostock's *Physiology*, where he will see good reason for believing that such is not only a mere opinion, but one resting on very slight grounds. These, then, being the leading facts and circumstances adduced by Dr. Alcock in support of his own physiological consistency, it is for your readers to decide how far they tend to overthrow the doctrine of Sir C. Bell and others—that a simple nerve performs only one function, and that a strictly special function requires a distinct nerve for its manifestation.

Dr. Alcock, lastly, complains that I have impeached his veracity, and am thereby equivocal and offensive. Surely such a complaint can only have had its origin in some strange misconception of my meaning. When I said that the accuracy of supposed facts must be established before a necessity arises for modifying the definition of principles, I was obviously alluding to what Dr. Alcock considered himself to have established as matter of fact, that "taste had two media of perception." I distinctly stated, that as I objected entirely to the mutilation of living animals as a mode of "determining the question," I

should not enter into any detailed examination of the contents of the paper; how, then, should I be understood as questioning Dr. Alcock's fidelity of narration? I sincerely hope this explanation will allay the angry spirit he has evinced, and which, I would gladly hope, has only been roused by some such misapprehension.

In conclusion, I can assure Dr. Alcock that he is thoroughly mistaken if he considers that, in this matter, I have been influenced by merely personal considerations. I never charged him, as he supposes, with want of candour towards me; but, considering that certain results, which he had obtained from what I believed to be an objectionable mode of investigation, were irreconcilable with those at which I had arrived by another mode, I expressed regret that Dr. Alcock had not had the candour to refer to them; more especially as he had drawn a similar inference to my own, from what I believed to be opposite data. It is impossible that I should have had any personal feeling on the puerile grounds Dr. Alcock seems to have imagined. On the contrary, had merely personal feeling influenced me, I must have felt gratified with the somewhat complimentary allusion made to myself in his original paper. But I trust that I am actuated by motives of a higher character than he appears to have supposed. I, too, like himself, am "seeking after satisfactory knowledge," and shall not be deterred from taking my own steps to obtain it, or from attempting the confutation of what I believe to be erroneous notions, even at the risk of being misinterpreted, and exposing myself to the ireful declamation of Dr. Alcock.—I am, sir,

Your obedient servant,
DANIEL NOBLE.

Manchester, Jan. 14, 1837.

ACTION OF THE HYDRIODATE OF POTASS,

ACCORDING TO A NEW HYPOTHESIS.

To the Editor of the Medical Gazette.

SIR,

As the purpose of your valuable journal is to afford a medium of instructive

communication to its numerous readers, they, in my opinion, are justified in opposing every new theory or hypothesis which appears to them erroneous, as well as to support that which they approve, by publishing the result of their experience.

Whatever fortunate practical results Dr. Hake may observe in the administration of hydriodate of potass, their publication to the medical world is meritorious; but when he attempts to establish a new doctrine as regards disease, and an hypothesis as to the *modus operandi* of his remedial agent, in an unsatisfactory manner to others, those may be allowed, through the same channel, to express their motives of dissent. Under such an impression have I perused the present communication.

Granting to Dr. H. that the hydriodate of potassa is a tonic and stimulant—that a stimulant produces on the animal economy an increased action, meaning in this instance, I presume, an abnormal one—and that such a condition may be either irritable, inflammatory, or debilitated, or all these occurring in a sequence; Dr. H. having ascertained under which of these diseases his patient labours, for supposition sake be it the inflammatory, he begins by converting that into the irritable, then proceeds with rendering the irritable the debilitative, and the latter he changes into the normal or regenerative. Reasoning thus on the gradation of the primary stage of disease into the secondary, thence that into the tertiary or final one, the induction is obvious;—the stimulant powers of the medicine convert inflammation into irritation, and the latter into debility, at which precise period come the tonic effects into force, to remove weakness, and regenerate the afflicted system.

The acute stages of rheumatism, exanthematous diseases, and gastritis, are excepted, the former on account of "febrile symptoms," and the latter on that of local irritation: and in this exception are also included "those disorders where there may be no excitement of the system, although there exist local irritation of the stomach and intestinal canal." Thence we are to infer it is not to be given when the excitement is general, nor when there is no excitement at all! This amounts to what logicians would pounce upon as a "contradiction of terms;" if not,

then why could not the chemical remove local as effective as excitement, particularly since we are informed of its capacity of converting an inflammatory stage into its sequence, either resolution, suppuration, or gangrene; but, I beg pardon, I mean the Doctor's new theory—irritation and debility. The reply is given in the paper, "we must wait the circumstances attendant on its exhibition being adapted to this kind of action;" by which, I suppose, is meant the medicinal, as that appears to me the relative to the antecedent, and not the morbid action. If I err in the former inference, then your readers are led to consider that the local irritation, or inflammation, is first to be removed, with a view of establishing the sequent stage of disease, when either the stimulant or tonic powers of the medicine come into operation, and cure. A very facile method, yet to me not altogether satisfactorily comprehensive.

In what varieties of chronic rheumatism and diseases of the skin it acts so specifically, the forthcoming cases will prove. In sympathetic gastrodynia, we are told, the "prime remedy" will magically act, provided its stimulating powers be antagonised by internal adjuncts, or counter-irritants of the anodyne kind, for by these the diseased locality is shielded from the injurious effects of an actual contact of the chemical, while its diffusive "tonic powers are active in elevating the natural tone of the debilitated mucous tissues." Thus the local irritation of the stomach, and the remote one of primary disease, are at one and the same moment wonderfully removed. The doctor's episode on the "invisible lovers of science, considering hypothesis as inimical to philosophy," is pretty, but he cannot deny that hypothesisists are too frequently like so many *ignes fatui*,—lead the inexperienced astray, and that these "admirable deceptions of nature" simulate Dr. H.'s favourite hypothesis. It is, indeed, an "admirable deception" of the intelligent hydriodate, by simulating the action of chyle to stimulate the lacteals, *who*, endowed with intelligence, finding the proffered stimulus not chyle, though hungry and thirsty, refuse the nauseous medicine; yes, even when that medicinal stimulus had aroused, excited them to the most active state for absorption.

So those Lilliputians are by the

robignagian laughed at for the vain effort of absorption, without the gratification to act! Tantalizing doom! The doctor tells us this is the reason why the enlarged mesenteric glands are so easily diminished. Mirabile! the mesenteric glands, then, are on the mucous surface of the intestines, surely the non-absorption of the hydriodate implies its presence there! Has it never occurred to Dr. H., that his Plummer's pills might have been, as they often are, so dry, hard, and unassimilable, as to remain in the course of the intestinal canal, until the hydriodate was given, when chemical decomposition may have ensued, and the iodate of mercury formed; a fractional part of a grain of which, in a few repeated doses, would cause the very powerful ptyalism ascribed as a newly discovered property of the hydriodate of potassa. The admirable metamorphic effect of this endowed chemical acts wonderfully well the thousand-and-one antipodian stages of disease, which by its beautiful mutation from malignant to tonic, are to its foe in open plain, vigorous, and in the ambush. Since the hydriodate possesses the "wonderful" property of affecting the nervous system, we might have almost expected an electric shock—the stimulant answering the positive, and the tonic the negative pole. As Dr. H. boasts it of such intelligent power in removing morbid "thickening structures from the bronchial mucous integuments," we may, *a priori*, expect similar beneficial results from its administration in ossifications of the aorta. Your readers will easily perceive with what "wonderful" tact the Dr. supports his doctrine, and deduces his inductions, for which he deserves the palm of ingenuity.

We have in him, *sub rosa*, a supporter of one of the leading principles of Hahnemannism, "a medicine producing a disease it is capable of removing." Finally, the wonderfully intelligent hydriodate produces pain in cases of enlarged prostate, while, Oh, beautiful deception of medicinal remedial nature! with what tenderness she diminishes the parturient throes of the aged female.

Apologising, sir, for the length to which my remarks have unwarily drawn me, I pass over others, and trusting that

this letter may find a place in your widely circulated journal,—I remain,

Yours obediently,

W. W. MORGAN, M.R.C.S.

Surgeon to the Bury Dispensary.

Bury Dispensary, near Manchester,
Jan. 7, 1837.

MORBID APPEARANCES IN AN AGED BEDRIDDEN PERSON.

To the Editor of the Medical Gazette.

SIR,

HAVING lately witnessed the post-mortem examination of an aged person, bedridden for thirty-one years, and whose case presented some very obscure symptoms, I send you this outline of the inspection, thinking it might be worthy of publication.

John Evans, of Towcester, aged 75, died 19th September last. He was very corpulent, and large in stature; his faculties were good almost to the last; his disposition was irascible; only a few months before death he attempted to cut his throat.

His appetite for food was not bad, and he rested tolerably well at night, considering his infirmities. Bowels generally regular; voice strong.

A difference of opinion prevailed respecting the disease he laboured under: some supposed him to be the subject of calculus, though the symptoms of this were obscure. Many years ago he was a patient in the Northampton Infirmary, under the care of the late Dr. Kerr; but after remaining there for many weeks he was discharged, his case being considered too obscure to admit of any immediate or beneficial treatment. Notwithstanding his labouring under the above symptoms, together with an irreducible inguinal hernia on the left side, it was conjectured by many persons that his complaints bore stronger indications of imposture than of real disease.

On dividing the integuments of the abdomen, a thick layer of fat was cut through, an inch in depth, before arriving at the tendinous expansion. The parietes being divided, and the viscera exposed, the peritoneum was found healthy,

containing about half a pint of serum tinged with blood. The great omentum was curled upwards to the arch of the colon. Stomach and intestines looked healthy. The liver rather small, of a pale brown colour; its structure by no means firm. The gall-bladder contained forty-five calculi, the size of small peas, with a small quantity of green bile; ducts pervious. In the right kidney were found seven calculi, embedded in its substance, each about the size of a nutmeg, forming a sort of cluster. The left kidney was devoid of such obstruction, though its structure was much softer than natural. The right ureter was pervious and healthy; the left was somewhat larger, and within it were found three irregular portions of calculous concretions, just at its entrance into the pelvis: how long they had been lodged there it is impossible to say. In short, the right kidney and left ureter presented an aspect totally different from the left kidney and right ureter.

On cutting through the urinary bladder, a large calculus was found inclosed in the fasciculi of the viscus, just behind the symphysis pubis. When removed it appeared smooth and firm, of an oblong shape, and weighed twelve drachms and one scruple; composed of phosphate of lime. I think it not improbable this stone had existed a great length of time. Two smaller calculi were found lying loose in the cavity of the bladder, near its base; these were of the same consistence: one weighed a drachm and a half, the other two scruples.

The coats of the bladder were much thickened; its mucous lining exhibited much redness. The prostate was not larger than usual for his age.

It would appear that the urine was principally secreted by the left kidney, as being the more healthy of the two. The patient voided his urine at proper intervals, without much difficulty. I do not think he ever required the catheter of late years; but I am informed that he frequently had a discharge of fluid from the umbilicus, exactly resembling urine both in smell and colour. He had always been of a temperate habit.—I am, sir,

Your obedient servant,

JOHN COLLIER, M.R.C.S.

Brackley, Dec. 30, 1836.

OPIUM IN TYPHUS FEVER.

To the Editor of the Medical Gazette.

SIR,

ALLOW me to send you the following remarks on the efficacy of opium in typhus fever, for insertion in the GAZETTE, should you consider them worthy.—I am, sir,

Your obedient servant,

CHAS. A. CADDY,
M.R.C.S., &c.

Bideford, Devon, Jan. 14, 1837.

Vol. 14th of the MEDICAL GAZETTE contains two excellent clinical lectures on typhus, by M. Chomel. The mode of invasion and appearances after death, &c. are therein accurately described; and to them I beg to refer, as preliminary to my remarks on the treatment.

In the year 1827, typhus was very prevalent in this neighbourhood, and the mortality very great. I attended at that time, amongst others, the family of a respectable farmer: five were ill, and three died. An old, experienced practitioner, visited with me. The treatment then adopted was the one recommended by the late Dr. Armstrong, and consisted of bleeding in the onset, with rhubarb and calomel, and purgatives, with a partial sponging of the body with cold water, &c. Not any of the preparations of opium were given.

In the autumn of 1834, I had about one hundred and twenty cases of typhus under my care, and the only fatal one was that of a girl about nine years old, who was in the third stage when first visited by me. The treatment adopted was the free use of the tincture of opium, in addition to those other means recommended. I shall endeavour briefly to illustrate the treatment by the following cases:—

On the 14th of November, 1835, I was called to visit John G—, a labourer, aged 32. I found him in the third stage; skin hot and dry; face dark red; delirious; sordes about the teeth, and the tongue brown and dry; and with tenderness over the stomach, &c. Applied a blister over the pit of the stomach, gave him thirty drops of tincture of opium in a little water, and ordered free applications of cold water externally, with change of linen twice

a-day, the removal of all unnecessary furniture from the room, &c. Diet, gruel and toast-and-water. The after-treatment consisted of two grains of rhubarb and three of magnesia every four hours, with a full dose of opium twice daily. He gradually recovered.

On the 16th, on my visit to the above, my attention was directed to his brother, aged 14, who sat pale and shivering over the fire. He had complained of fatigue and shivering on the previous evening. He was ordered to bed, and took an emetic, followed in two hours by twenty-five drops of the tincture of opium. On the following day all symptoms of fever were gone.

When aperients are required, to counteract the astringent effect of opium, or otherwise, I have found castor-oil the safest; but if the bowels are irritable, instead of rhubarb and magnesia, I substitute two grains of Dover's powder, or the compound powder of chalk, or carbonate of soda; restricting the diet, in all cases, to gruel, arrow-root, coffee, tea, and toast-and-water. No fruit or preserves, or animal broths, during the existence of fever. Bleeding is generally required after the first shock is past; and in all cases where the first stage is fully developed, cupping or a blister over the stomach. I have had many cases of typhus under my care during the last autumn, and in all opium was given, and with the greatest success; acting as a charm on the cerebral affection so generally attendant on typhus.

MIDWIFERY.

EXPULSION OF THE PLACENTA BEFORE THE BIRTH OF THE CHILD.

To the Editor of the Medical Gazette.

SIR,

By inserting the following obstetric case at your earliest convenience, you will much oblige

Your obedient servant,
J. H. BULL.

Lindfield, near Cuckfield, Sussex,
Jan. 5, 1837.

On the morning of the 7th of December, I was summoned to attend a poor

woman in labour with her sixth child, residing at Ditchling Common, about five miles from hence. Upon reaching her abode the nurse immediately came down stairs, and informed me that about two hours before she had had most alarming hæmorrhage, from the effects of which much exhaustion ensued; however, on the recurrence of her labour pains she had expelled the placenta, and the foetus still remained *in utero*. To my great astonishment, on visiting the patient, I found the nurse's statement quite correct. The placenta was placed in a receptacle on the bed, the funis not as yet separated, and, of course, no pulsation perceptible; and, to add to all the foregoing disasters, there was a presentation of the arm as high as the axilla. Notwithstanding which, to my great satisfaction there was powerful uterine action. After encountering some difficulty, I succeeded in turning the child, and delivered her forthwith. I attribute the child's death solely to the expulsion of the placenta, as, from all appearances, its demise was of recent occurrence. Suffice it to say, the poor woman has had scarcely an untoward symptom since, and is now quite recovered.

SUPPOSED RUPTURE OF THE INNER COATS OF THE BLADDER,

WITHOUT INJURY TO THE INVESTING
PERITONEUM.

To the Editor of the Medical Gazette.

SIR,

Should you consider the following case sufficiently interesting to the medical profession to deserve insertion in your valuable publication, it is at your disposal.

I remain, Sir,
Your obedient servant,
WM. T. KEAL.

Oakham, Dec. 20, 1836.

Early on Tuesday morning, Dec. 29, 1835, I was requested by a medical friend to accompany him a few miles, to advise in the following case: the particulars were communicated by my friend in our way to the village:—

The subject of the case was a young man, about two and twenty years of age: he had been labouring under stricture of the urethra about a fortnight, the consequence of a recent gonorrhœa, when he was knocked down by a horse, on the 26th, about noon. The horse in stumbling fell upon the lower part of the patient's abdomen; he felt pain soon afterwards about the pubic region, accompanied with a more frequent desire to pass his urine, which he accomplished with no more than the ordinary difficulty. In about eight hours after the accident the difficulty increased, and soon retention became complete.

Up to that period there had been no discolouration of the urine. The retention continued till Monday evening about eight o'clock, when he passed a moderate quantity, which relieved him from pain, and he slept from ten till two o'clock. On awaking there was much pain, with an extreme desire to make water.

His medical attendant was now for the first time sent for, and upon his arrival, finding the retention accompanied with much agony, immediately returned home (a distance of two miles) for a catheter.

On his return the patient informed him, that during his absence, in attempting to evacuate his urine, he had experienced a sudden "crack" (to use his own expression), and an immediate sensation of cold pervading the pubic region, at the same time finding relief from the distressing pains under which he was previously suffering. Upon our arrival we found our patient comparatively easy, though there was tenderness of the abdomen, with a sense of distension, but no circumscribed tumor, as in cases of retention without laceration. I immediately suggested the introduction of the catheter, and at least two quarts of bloody urine were drawn off. The stricture caused considerable impediment to the introduction of the catheter.

The patient experienced much relief after the operation. The pulse being full, I advised a copious bleeding from the arm, to be followed by leeches to the pubic region, with subsequent fomentations. I also suggested a saline aperient, afterwards calomel and antimony in repeated doses, and an opiate at bed-time. It was considered essen-

tial to pay due attention to the frequent use of the catheter.

I did not see the patient again, but was informed by my friend, that after using the catheter for two days, he was able to pass his urine without its aid, and was free from all abdominal pain; and he considered him recovered from the injury of the bladder. The stricture was subsequently cured, as was also an attack of orchitis. The patient has continued free from any consequences whatever of the injury.

THE NEW PHARMACOPŒIA.

NOTE FROM MR. EVERITT, IN REPLY TO MR. PHILLIPS.

To the Editor of the Medical Gazette

SIR,

I AM quite at a loss to see the appropriateness of Mr. Phillips placing, in relief, in his letter to you, misprints which did not occur in your journal, although they did appear in the *Lancet*.

Mr. Phillips attributes the error in the Latin edition, of ordering three measures of water in the room of two (or more correctly, one and three-quarters), to be mixed with one measure of the strong liquor ammoniæ, to reduce it to the weaker, to a misprint; by a curious coincidence, the same misprint occurs in his English translation. The last paragraph of Mr. Phillips' letter, in which he apparently has me on the hip, will lose all its point when a reference is made to that part of my communication to which he alludes. Every one knows how changed the meaning of a few words may become by separating them from their associates. In giving the process for making liquor ammoniæ, it is very evident I confined myself to a general description, and did not intend to give the exact strength of the product; for I said, "put about" (a little word omitted by Mr. Phillips) thirty parts of water into the receiver; and then, a few lines further on, I contended that ten ounces of sal-ammoniac can, in practice at any rate, make thirty fluid ounces of liquor ammoniæ of .960, in the room of only fifteen, as prescribed.

	Grains of Ammonia.
10 oz. of this salt contain ..	1511
fluid oz. at .960 contain ..	1260
<hr/>	
se very liberal allowance)	251
6th) for loss	

ce, I think, I did not wish to get ammonia out of the salt than it led; although, on the other I do contend, that the process of Pharmacopœia, where 881 grains 1511 are admitted to be lost, is rich no manufacturer will follow, which ought not to have been in tion of 1836.—I am, sir,

Yours sincerely,

THOS. EVERITT.

Medical School,
Ex Hospital, Jan. 16, 1837.

ASES OF NORTH SHIELDS, D THE SURROUNDING DISTRICT.

Editor of the Medical Gazette.

R,
y not be uninteresting to some of readers who reside in parts of the om remote from this, to learn ing of the diseases which have prevailed during the past year district, together with the state weather during their rise and ss; and as the weather during eriod has been of a marked and al character, so have diseases as- somewhat of a peculiar nature.

winter of 1835-6 was unusually he thermometer being rarely be- , except on two or three occasions, we had slight frost, which never ued more than six and thirty at a time; this mild weather con- until nearly the end of February, the whole of which time little int seemed to exist; in point of have invariably found mild open s infinitely the most healthy, in of the old proverb: the only com- which manifested itself during eriod was the small-pox, which ntinued to hold its course up to the t time, apparently quite unin- ed by atmospheric changes of any

At the end of February, the east et in with even more than its usual ess, bringing in its train coughs, broats, and inflammatory com-

plaints, more especially of the lungs and air-passages: an epidemic resembling influenza made its appearance, not un- frequently accompanied by bronchitis; measles also prevailed, with a great ten- dency to croup; acute rheumatism was also of common occurrence; altogether a decided inflammatory diathesis per- vaded all diseases occurring at this time, and I had occasion to call the lancet into requisition more frequently than for three or four preceding years. Things con- tinued much in this state until the be- ginning of June, up to which time no rain had fallen, occasioning a serious want of herbage: early in June rain began to fall, and continued with little intermission during the whole summer and autumn, the wind being for the most part W. and S. W., the weather being cold, and thunder of frequent oc- currence. A visible change was effected in the nature of diseases by this altera- tion in the weather; the inflammatory diathesis disappeared, as also did mea- sles, which was succeeded by scarlet fever, and an extraordinary hæmorrhagic tendency manifested itself, appearing most commonly as hæmoptysis, but also in the tendency of the exanthemata to terminate in purpura, and in the fre- quency of abortion and of uterine hæmorrhage after delivery. I may also here state, that cutaneous diseases were more common, and strumous tumors of more than usual frequency, probably from the functions of the skin being im- paired by the state of atmosphere; but what is not a little singular, I did not see or hear of a single case of autumnal cholera, nor even of diarrhœa.

In October we had a considerable fall of snow followed by a succession of rainy weather, which abated at the beginning of December, from which time it con- tinued mild and dry until the 23d, when a snow storm set in, accompanied with thunder; a severe frost succeeded, and the snow lay until the 5th of January, since which time we have had a rapid succession of frost and thaws. I am the more particular in noticing this, as the influenza made its appearance on the 6th, and has gone on increasing ever since, and I am certain I do not over- rate it, when I say that at this moment ten per cent. of the population of this district are labouring under it: its usual mode of attack here is, by cold rigors, intense pain in the head, coryza, irrita- tion about the trachea, incessant cough,

extreme lassitude, and pains in the limbs. The best mode of treating it seems to be, to confine the patient to bed; diet, warm diluents; and such remedies as will keep the skin open, and promote expectoration. *Mist. salinæ* and *vin. ipecac.* seems to answer both indications. I have seen no case in which bleeding was requisite, or even admissible; and one peculiarity of the disease is, the disposition to fainting, which is readily induced by active purging, rendering it advisable to administer such aperients as do not lower the system.

In taking a review of the diseases mentioned in the foregoing relation, we can feel no surprise that the cold east winds should have given rise to inflammatory complaints; but it is by no means so obvious what could occasion so great a tendency to hæmorrhage. How far cold and moisture, together with a highly electrical state of the atmosphere, is capable of producing such results, the present state of our knowledge does not admit of our being able to determine; but it is a subject well worthy of attention, and one whose investigation will probably lead to important results.

I remain, Sir,

Your obedient servant,
EDWARD GREENHOW, M.D.

North Shields, Jan. 14, 1837.

STRANGULATED INGUINAL HERNIA.

OPERATION AND RECOVERY.

To the Editor of the Medical Gazette.

SIR,

I AM induced to offer the following case of hernia for insertion in your valuable journal, on account of an appearance which I believe to be unusual. I allude to the peculiarity of the contents of the sac.

Samuel Hart, æt. 45, drayman, states that he has been subject to a rupture (oblique inguinal) on both sides for fifteen years, which he has always been able to return with readiness. Having lately obtained a new truss, and finding the pressure from it uncomfortable, he took it off on Saturday morning, December 30th. Shortly afterwards, whilst walking from the fire to his bed, the

rupture on the left side came down, and he was not able to return it. He soon began to feel pain across the abdomen, attended with vomiting, which continued with little intermission. The rupture, which at first was not larger than a walnut, had been gradually increasing; and when I saw him, for the first time, on the following morning, at 10 o'clock, it presented these appearances:—Its form was pyramidal, measuring about six inches from the external abdominal ring downwards, and about three inches and a half in its transverse diameter; it had a tense and elastic feel; no pain was experienced upon pressing any part of the tumor, except at a point immediately over the seat of the stricture. He complained much of pain in the abdomen, just below the umbilicus, which was also aggravated upon pressure. The abdomen was soft and yielding; pulse 100, somewhat incompressible; tongue moist, and slightly furred; bowels not open since yesterday morning; countenance very anxious. After fruitless efforts to return the rupture, I bled him to faintness, and again renewed the attempt, but was equally unsuccessful. He was then ordered to keep ice constantly applied, and an active purgative was prescribed. At half-past two my father accompanied me to visit the patient. We found him nearly in the same state, but stercoraceous vomiting had supervened. After again employing the taxis, a tobacco enema was administered: great depression of the vital powers ensued, but the hernia continued irreducible. We then judged it better to leave him for an hour or two undisturbed, directing him to continue the application of ice, being determined, if after that time the hernia remained irreducible, to proceed immediately to the operation.

At half-past six, having once more endeavoured to return the intestine without any better success, I proceeded to perform the operation, in the presence of my father and Dr. Rowland. It is unnecessary to describe all the stages of the operation: the sac having been exposed, there was considerable difficulty, on account of its great tenseness, in pinching up a portion for the purpose of dividing it. An opening being made, about four ounces of serum gushed out. When the sac was laid open, a large mass of coagulable lymph presented itself, having the appearance

of calf'-foot jelly, only of a darker colour, not adherent, and which totally concealed the protruded intestine. This jelly-like substance, which formed the bulk of the tumor, being removed in one large mass, a moderately sized knuckle of intestine was observed, in a highly vascular state, with laminae of lymph adherent to it, of the same colour as that contained in the sac. The sac itself was quite free from inflammation. The stricture being divided, the operation was completed in the usual manner. An opiate was given at bed-time, and he passed the night without much pain. In the morning he took some castor oil, which not having produced any effect at noon, an injection of warm water with some salt was administered. The bowels were soon freely opened, from which time he has recovered without one untoward symptom.

I remain, sir,

Your obedient servant,

HENRY TAYNTON.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALKBERT.

Practical Observations on Nervous and Sympathetic Palpitation of the Heart; particularly as distinguished from Palpitation the result of Organic Disease. To which are prefixed some General Remarks on the Use of the Stethoscope and the Employment of Percussion, in the Diagnosis of Diseases of the Heart and Lungs. By JOHN CALTHROP WILLIAMS, M.D. Edinburgh.

THE object of Dr. Williams is to point out the distinguishing marks of palpitation dependent on functional disturbances. We do not find, in the general remarks which he makes on the use of the stethoscope and the employment of percussion, any thing of particular interest or novelty; indeed that part of the work is almost entirely composed of extracts, while the writers referred to are nearly all "learned and talented," and their works all either "valuable" or "very valuable." A distinct, if not a general view, is given of nervous and sympathetic palpitation, and several very good cases adduced in illustration. In one the disease originated in the

sudden communication of distressing intelligence, which led to movements of the heart not violent, but tumultuous, with a thrilling sensation in the limbs: occasionally the palpitations were accompanied by a "cooing sound," and at other times the pulse was intermittent. The patient recovered gradually under the use of aperients and tonics, particularly iron, which was freely administered. In the second case, a young lady addicted to starving and tight lacing, became affected with palpitation.

"She could not bear to lie down because of the heart's pulsations, which she was constantly counting; she had at times the fear of suffocation; her appetite, which she had long refused to gratify, in the course of time left her; an annoying dry spasmodic cough, the sound of which was noisy and metallic, supervened; her legs swelled; and feeding her imagination with every kind of apprehension of evil, she became so reduced and so irritable, that she was obliged to withdraw from society. She always described the movements of the heart as of a fluttering kind, accompanied with a sensation of sinking, and a feeling of emptiness in the epigastrium. They varied much in regard to the degree of intensity; and at times, even when she complained of them as very distressing, they were scarcely perceptible to the observer. The sound proceeding from the contractions of the chambers of the heart, always appeared clearer and louder than natural."

This patient also did well, the treatment consisting in anti-spasmodics with digitalis, followed by mineral and vegetable tonics.

The third case, given as one of nervous palpitation, appears to us to have been attended with organic disease, relief having been afforded for a time by the remedies employed.

The case which follows next is extracted from the Hospital Reports of La Pitié. After which comes one treated by our author, in which the heart affection depended upon the irritation caused by tape-worm. The history is interesting.

"A young lady, 22 years of age, was affected not only with the ordinary symptoms of tænia, viz. fixed pain in the left hypochondriac region, voracious appetite, restless nights, disturbed dreams, febrile exacerbations, occasional syncope, and other similar phenomena;

but she suffered, likewise, distressingly from periodic attacks of sympathetic palpitation, accompanied at times by great cerebral excitement—to such a degree, indeed, that she was obliged to pass the night in an upright position, in an easy chair, otherwise she became temporarily delirious—a state which on several occasions threatened to assume a lasting character. The oppression and sense of suffocation she endured during the more violent paroxysms, were truly distressing, and would have led any one, not conversant with the diagnosis of the organic disease of the heart and lungs, to suspect that something beyond morbid sympathy created the extreme constitutional derangement she suffered. During the paroxysms, the heart, it is true, beat most violently, and with a loud clear sound; the latter, however, proved that the organ was not affected with hypertrophy, for then the sound is generally dull and obscure. The attacks were periodic, and occurred always half an hour or so before the regular hours of repast, and were relieved by repletion. This would scarcely have been the case, had the palpitations depended upon structural disease. The action of the heart was not greater at one part of the præcordial region than at another, nor was the sound louder in any particular situation. The action of the organ was regular, though quicker and more forcible than in a state of health. The entire organ appeared to labour under an increase of irritability, and the consequence was, that every part acted more energetically than it should have done,

The lady whose case I have just related, was treated with daily doses of oil of turpentine, jalap, calomel, colocynth, and other purgatives. The irritation of the system was relieved by the frequent application of leeches to the temples, the employment of refrigerants to the head, and the internal use of anti-spasmodics, such as valerian, castor, camphor, hyoscyamus, and opium, as the varying circumstances of her case demanded; and her restoration was finally completed by a course of vegetable and mineral tonics. During the space of fourteen months, she voided, in separate portions, many yards of tapeworm, varying in length from an inch to upwards of a foot and a half. She is now in the enjoyment of perfect health.

The last case adduced is simply one

in which the application of cold to the feet, during menstruation, was followed by a sudden cessation of the discharge, after which palpitation supervened. It presents nothing remarkable.

The general directions given by Dr. Williams, in judging of the nature of the palpitation in any given case, are contained in the following extract:—

“We must ascertain by the hand, ear, and stethoscope, whether the abnormal action of the organ be universal or not, over the whole extent of the præcordial region. If it be found on both sides of the heart, and not on one part more than another, it leads to the conclusion that the palpitation is merely a functional disturbance; but this does not constitute positive proof. We must examine, at the same time, by striking over the region of the heart, either by the fingers, or through the medium of the pleximeter, whether the dull sound peculiar to this region be not of greater extent than natural. This induces the conclusion that there is no dilatation, nor effusion into the pericardium.”

A Bed-Side Manual of Physical Diagnosis applied to Diseases of the Lungs, Pleura, Heart, Vessels, Abdominal Viscera, and Uterus. By CHARLES COWAN, M.D. Author of the Translation of LOUIS on “Phthisis.” Sherwood. 1836.

This little volume has the unusual recommendation of being precisely what it professes. It gives a concise but clear account of the most important physical signs of disease, as connected with auscultation and percussion. It costs half-a-crown, and will burden no one's pocket. Pupils would do well to have it always with them, in going round their hospitals.

MEDICAL GAZETTE.

Saturday, January 21, 1837.

“Licet omnibus, licet etiam mihi, dignitatem Artis Medicæ tuæ; potestas modo veniendi in publicum sit, dicendi periculum non recuso.”

CICERO.

THE EPIDEMIC CATARRH.

Two facts connected with the prevalent epidemic must press themselves on the notice of every member of the commu-

nity—the numbers cut off by it, and the severity with which it attacks the old. The daily obituaries in the newspapers are swelled prodigiously beyond their ordinary dimensions, and we question whether even in the cholera times those lists were so heavy. The inference from this, perhaps, is not exactly that the mortality is greater, but that it falls more on people in the upper and middle classes. The cholera raged destructively among the poor, and carried off comparatively few victims from the upper classes; but the epidemic catarrh, in its insidious march, seizes indiscriminately on all sorts of persons, and, while much less formidable in its specific mortality, is found in its results to be little less alarming; for its absolute mortality is made up from a wider range.

We mentioned last week how actively the profession have been employed since the epidemic has prevailed: their activity and full occupation have not diminished since; but in a few weeks, we presume, their services will be less required; the disorder will have subsided and been forgotten.

This is but too frequently the history of epidemics amongst us: while they prevail, they create a sensation; the method of treatment is attended to, but little if any notice is taken of the producing causes, or of the mode by which the community might be protected from future attacks. The essential features of the disorder are not observed in such a manner as that they would be recognized again on a subsequent visit, and so these epidemics come and go, free as air, and making at most but a temporary impression.

Much is lost to medical science by the apathy among those who profess to cultivate it in respect to these matters: there is no concert, no understanding, as to how diseases which widely

affect the community are to be observed, — no general inferences are drawn which might promise security to the public health. It is obvious that much good might be effected in the attainment of these ends by the impulse which an able and efficient Government Board could give: but as it is, and proverbial almost as is the jealousy which the medical practitioners of this country have ever entertained of being governed or directed by any Board in authority, nothing can be expected from that source. There is still an alternative in the voluntary union of the members of the profession; and it is with pleasure, mingled with sanguine anticipations, that we recollect it is one of the avowed objects to be pursued by the Provincial and Branch Associations—to gather ample information respecting epidemic disorders, to study their phenomena, ascertain their laws, and to counteract, if possible, their baneful influence. We hope that the opportunity afforded by the present malady, which prevails so extensively throughout the country, will not be lost, and that by the united labour of many, concentrated afterwards by the sound judgment of a few deputed to generalize the results, we may become perfectly acquainted with the causes, characters, and, in short, the laws, of at least one epidemic, which seems likely to visit us often, as it has, no doubt, been with us before.

Were we called upon to point out the character and distinctive features of the prevailing disorder, we should say that its chief peculiarity has consisted in the extent to which the lungs have been implicated, the mucous membrane lining the air-passages being in many cases inflamed, and after a few days overloaded with viscid secretion, interfering with the arterialization of the blood. The oppression of breathing is in many cases urgent, and attended by

great pain along the lower edge of the ribs, and in the epigastrium. The pulse is for the most part soft, and depletions are borne very badly: in those in whom they are carried too far, delirium is apt to supervene. Numerous cases have proved fatal, and post-mortem examination has shewn the membrane lining the air-passages to be inflamed, from the trachea into its minutest ramifications, with condensation of portions of lung, but the pleura suffering comparatively seldom. Even in slighter cases the recovery is tedious, and the patients go grumbling on for many days, with loss of appetite, great languor, and something of ill humour.

The cause of the general seizure is freely talked of as no mystery. It is traced to the change which so suddenly occurred in the atmosphere, from great dryness to great humidity, both states being accompanied with a severe depression of temperature. It was not any remarkable alteration in the degree of temperature that gave rise to the morbid consequences, for we have had scarcely an hour of warm or even temperate weather these six weeks, but the profusion of cold damp moisture with which the air became loaded on the occurrence of the thaw, has been, undoubtedly, a main source of the disorder. There may be, and doubtless are, other qualities in the air which are influential as causes of the prevalent catarrh: yet of these we must, at least for the present, be contented to remain in ignorance; they cannot be appreciated by any powers of analysis which our chemists or meteorologists possess.

A violent alternation from great cold to comparative heat has sometimes originated an epidemic. One of the most extensive and destructive epidemic catarrhs with which Europe was perhaps ever afflicted, was owing to this cause. It commenced in Russia, in a locality where

the thermometer, after standing for some time at -35° Fah., rose in the course of twelve hours to $+5^{\circ}$, indicating a change of temperature to the amount of *forty* degrees. Forty thousand persons were almost immediately seized with epidemic catarrh.

But what happened on the spread of this very epidemic? It traversed Sweden, Denmark, Upper and Lower Saxony, and other regions farther west, without apparently requiring any similar change of temperature in the places it visited; at least no change in any way remarkable was observed.

That cold weather is peculiarly favourable to the rise and progress of the disorder, we know from statistical facts. M. Andral, in an able sketch of some of the chief epidemics which have prevailed in Europe, states that, of fifty-six catarrhal seizures like the present, twenty-two occurred in winter, twelve in spring, eleven in autumn, and five in summer; while in respect to epidemics of other kinds the case has been very different,—of fifty epidemics of dysentery, for instance, thirty-six prevailed in summer, twelve in autumn, one in spring, and one in winter.

How much the winds, and certain supposed electric states of the air, may have influence, it is exceedingly difficult to say. East and north-east winds have been considered in this country as prejudicial to health, yet they can scarcely be connected with the origin of the present catarrh, for there has been no remarkable prevalence of winds from those quarters. And as to electricity, the inquiry is equally barren of satisfaction. The air changes frequently from a positive to a negative state, without, in the great majority of instances, giving rise to any appreciable result in regard to health. The deficiency of electricity in the air, rather than any surplus of it, would seem to be favourable to the pre-

valence of epidemics; for in those lofty flat regions, far above the level of the sea, electricity is almost wholly absent from the air, and epidemics are common. On the other hand, Volta himself analysed and compared the atmospheres of countries attacked with, and free from, epidemic disease, without being able to find any sort of difference between them.

We have noticed the fact, that in the present epidemic the persons most susceptible to its influence are the elderly: this may be considered as a peculiarity of the disorder, for on other occasions the young and adult have been equally, if not more, exposed. But there is the greatest diversity in this respect: individuals of every age, of every temperament and constitution, are liable to epidemic attacks at different times. Sometimes the feeble are attacked, sometimes the robust. In one of the epidemic catarrhs which was formerly very destructive in this metropolis, persons of a sanguine temperament were its chief victims. Children were spared in the Russian influenza, while the robust and stout were the principal sufferers.

What are the chances in epidemics of this kind? It is very important to observe, that the prognosis of a disease prevailing epidemically is always more serious than when the same disease is met with in a sporadic form: what would in the latter shape be slight, may prove in the former mortal,—in statistical language, the cypher of the mortality is raised. But much must depend on the age of the persons attacked, and their stamina: it is to be recollected, also, that the prognosis varies considerably according to the period of the epidemic. In the onset, or presently after, the danger is greatest; it declines as the visitation approaches its close.

Ozanam, in his *History of Epidemics (1817-1823)*, gives the following as an estimate of the mortality of the princi-

pal diseases which attack large numbers of mankind simultaneously:—

Catarrh carries off per cent. . .	2
Scarlatina	5
Dysentery from 18 to	40
Croup	30
Typhus fever	60
Puerperal fever	66
Malignant pneumonia	70
Yellow fever from 75 to	80
Plague	73 to 80

In glancing at this list, however, we must not be deceived: some of the disorders with the lowest cyphers may happen to prove the most destructive; and it is possible that even catarrhal fever, with its low rate of specific mortality, may carry off as great a number of victims as the plague. We do not ourselves rate the specific mortality of epidemic catarrh so low as it is stated in the preceding table; but even if we did, we should still see sufficient reason for apprehension when we consider the vast numbers of persons attacked. The comparatively slight symptoms which mark its invasion, together with the many instances of escape, appear to deprive it in great measure of its terrors: we doubt not, however, that were it possible to obtain a correct return of the number of victims, the contemplation would be not a little appalling.

COLLEGE OF PHYSICIANS.

TRANSLATIONS OF THE PHARMACOPŒIAS.

AN advertisement has been going the round of the newspapers and journals for the last month, announcing that a translation of the new Pharmacopœia, from the pen of Mr. Phillips, is forthcoming, and that the College of Physicians will “resist” the publication of any other. Now we have always understood that the copyright of a work did not extend to translations of it; and it is therefore our belief that the College have no power to “resist,” as they call it. But if any such exclusive

power did exist, we should like to know why some member of their body was not entrusted with the task of editing the translation? If this be intended as a mode of remunerating Mr. Phillips for his assistance in regard to the chemical manipulations, we must take leave to say it is about the very worst that could have been devised. On former occasions translations of the Pharmacopœia have appeared without the College *resisting*; what, then, in the name of common sense, has induced them at the present moment, and under existing circumstances, to publish such a stupid, illiberal, impolitic, and empty manifesto? We have been told, indeed, that the College have not sanctioned it, and know nothing of it. We sincerely hope that this may prove to be true; but if so, we are again compelled to ask why was it not instantly—(within the first twenty-four hours)—contradicted? Do they think that these are times in which they may quietly repose in apathetic indolence, trusting to character, forsooth, as their safeguard? They have active enemies in every quarter; and if they are not prepared to show a corresponding degree of energy by taking the lead in every measure which is for the general good of the profession, instead of attempting to establish any trumpery monopoly like the present, we would advise them to give up the struggle at once, and resign themselves to their fate with what degree of complacency and gracefulness they may.

SEPARATION OF THE ST. THOMAS'S AND GUY'S HOSPITALS.

THIS event, to which we alluded last week merely as a probable result of the recent unfortunate occurrences, has actually taken place, as appears from the following resolutions. We think the circumstance is very much to be regretted.

At a General Quarterly Court of Governors of St. Thomas's Hospital, held on Wednesday the 18th instant, the subjoined resolutions of the Committee were confirmed, and passed unanimously:—

Resolved,—That the Committee having taken into consideration the letter received from the physicians and surgeons of this hospital, and having adverted to the recent outrage committed by some of the pupils of Guy's Hospital in the operating theatre of St. Thomas's, are of opinion that the pupils of Guy's should no longer be permitted to attend the surgical practice and operations of St. Thomas's, unless they are also pupils of St. Thomas's.

In coming to this conclusion, the Committee desire to express their regret that the union of the two hospitals, which existed for a long period of time, beneficially alike for the schools of both, and for the public advantage, to the year 1825, should then have been dissolved by the authorities of Guy's, without consultation with, or the consent of, the Governors of this hospital.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

IN our report of the proceedings of last meeting (Tuesday, Jan. 10th) we were obliged to omit the following abstract of

Dr. Hume Weatherhead's Paper on Inflammation.

The object of the paper is to illustrate and determine the essential nature of Inflammation, by an analysis of its deducing them all as one consecutive series of effects, dependent for their relations on one another.

The author prefaced his remarks by observing that all the phenomena of the living system, both morbid and healthy, owed their origin to nervous influence; that it was the nerves that determined, in the first instance, the rush of blood to a part inflamed; that the increase of temperature, as a symptom of inflammation, was the result of this afflux; that from the same source proceeded, directly and indirectly, the tension and tumefaction, and that the attendant pain had a similar origin.

The first effect of an excitant or irritant, he went on to observe, was to attract the blood to the seat of the irritation; but if this effect was kept up beyond a certain period, or carried beyond a certain degree,

while the excitation continued to attract as much blood as before, the power of the capillaries to forward it diminished proportionately with the exhaustion produced by their prolonged over-action. As long as the increase of action in the capillaries was in a ratio with the increased supply of blood, inflammation could not be said to exist; but as soon as the inverse of this took place, by which one became disproportionate to the other, this very circumstance of itself constituted and established that morbid condition we call inflammation.

The author next defined the distinction between this state and congestion. In the former the plethora existed in the capillary arteries, while in the latter, the turgescence had its seat more particularly in the capillary veins.

The paper proceeded to treat of and to exemplify the power of the arteries to determine blood to particular parts independent of the heart, and then deduced the increased temperature of a part inflamed from the difference of capacity for caloric the blood underwent in changing from arterial into venous, and how the release and evolution of the latent caloric which went on in the capillary system, kept up the temperature of the surface in health, and how its inordinate evolution alone made it a morbid symptom as, most conspicuously, as well as conclusively, exemplified in scarlatina.

However, while there existed in the acute stage of inflammation an increased determination of blood to a part, the moment it entered vessels not intended in their natural state to convey red globules, a state of hæmostasis necessarily ensued. From this state of engorgement proceeded an effusion of serosity into the cells of the contiguous cellular membrane in common phlegmon, or into serous cavities, when serous membranes were the seat of inflammation. It was from this circumstance (most manifestly exemplified in certain vesicles, and by the effects of a blister) that the author adduced proofs that pus was nothing else than serosity of a particular quality, which, by a spontaneous change its albumen undergoes, and a partial absorption of its lymph, had been converted into pus—an opinion he sustained by quoting the celebrated experiment of Van Swieten on ulcers, the purulent change which serosity undergoes under our eyes in various exanthematous pustules, how promoters of serous secretion were also promoters of suppuration, and lastly, how strictly pus and serosity were identical in their chemical composition.

The author next took a review of anasarca and its causes, as furnishing addi-

tional confirmatory illustrations on the morbid physiology of the capillary system; how both œdema and anasarca invariably proceeded from vascular hæmostasis, and that the former could be produced artificially, as by a ligature; why the fluid effused in these diseases did not change into pus (the deficiency of that which forms the globules of purulent matter, albumen.)

He next explained the pathological formation of an abscess, elucidating his views on the subject by analogy with the change of a vesicle into a bleb—the breaking down of the cellular septa—how that tumefaction was always greatest where cellular membrane most abounded, and was most lax—how serous and fibrous tissues seldom suppurated, and when they did it was always sparingly; and why a common phlegmon should readily suppurate, and a boil should not.

Pain as a consecutive symptom of inflammation next came under notice; and it was shewn that this was mainly attributable to the distended state of the blood-vessels extending or stretching the tissue or structure in which the inflammation was seated; and that, *ceteris paribus*, the pain was always most severe in those tissues that yielded with the greatest difficulty.

Gangrene and sphacelation were next briefly referred to, as results rather than phenomena of inflammation, since both are to be regarded, the one as a partial, the other as a total, extinction of the vital powers of the part—results that may be induced without any previous inflammation.

The paper closed with some detached observations introduced as corollaries, and referred chiefly to serous effusions. The author was inclined to regard the principal function of the cells of the lax cellular membrane as reservoirs spread over the surface of the body, to receive a portion of the circulation when from some morbid cause the blood in the superficial capillaries was stopped or impeded in its course. The splanchnic cavities performed a similar office to the large viscera when obstructed; and the author concluded his observations with narrating an unusual case of ascites from scirrhus liver, in which several of the exhalants opening on its anterior aspect were so enlarged, as readily to admit the end of a probe.

[It has been arranged, as we mentioned in our last, that the discussion of this paper is to take precedence of other business at the next meeting on Tuesday next.]

BRITISH MEDICAL ASSOCIATION.

MEETING AT EXETER HALL.

A MEETING of the medical profession, convened by the new Association, was held at Exeter Hall on Thursday evening last. The weather was extremely unfavourable; notwithstanding which, upwards of a hundred gentlemen were present. Many were unavoidably absent in consequence of the prevailing epidemic. A few minutes after 7 o'clock Dr. WEBSTER, the Chairman, attended by several members of the Council, entered the room, and was loudly greeted.

The CHAIRMAN, in opening the business of the meeting, said that it was convened for the purpose of listening to a statement of the principles and objects of the Association, and of the means by which it was proposed to carry those objects into effect. At a provisional meeting which had been held, it was resolved that the Society should be called THE BRITISH MEDICAL ASSOCIATION; that a council should be formed, and officers appointed; and that a code of laws to regulate the proceedings of the Association should be drawn up, subject to the consideration of a subsequent meeting. The names of the gentlemen who composed the Council would now be read, and the code of laws would be submitted to the meeting.

The names of the Council being read,

The CHAIRMAN proceeded to read an address of some length, for the purpose of explaining more fully the principles and objects of the Association. It first referred to the unsettled state of the medical profession of England, as it regarded the consulting physician, the surgeon, and the general practitioner. Three causes were assigned for that state; first, the neglect of medical affairs by the legislature; secondly, the selfishness and misgovernment of those who ought to encourage medical science, and protect the profession; and thirdly, and chiefly, from the apathy, jealousy, and disunion, existing in the body itself. Various attempts had been made to redress their grievances, but in vain. The burden was, at length, become almost insupportable. Systematic attempts were still made to degrade and lower the respectability and usefulness of medical practitioners; and the cup of endurance had risen to overflowing. The profession was now aroused to a sense of the duty it owed to itself, and the present was regarded as a most fit time to obtain redress. Many divisions and distinctions prevailed which were unnatural and degrading. The interests of the three branches were placed in

variance; and one was often accused of infringing on the other's provisions. At the fountain heads, as they were called, of professional honour and dignity, the colleges and corporations, unseemly distinctions prevailed, inconsistent both with what was due to the members themselves, and to the public at large. Those institutions possessed undue powers, and were governed by defective laws. Even if the antiquated charters of Henry VIII. and of James I. also of George III. together with more recent provisions, were duly executed, they would still be totally inadequate to the wants and requirements of the profession, as well as incompatible with the spirit and intelligence of the times. In some cases the powers those institutions possessed had been employed for the purposes of persecution and oppression. The address then referred to the College of Physicians, and complained of the unjust and degrading division of the Fellows and the Licentiates. The first were a sort of aristocratic rank, pluming themselves on their supposed superiority, in having been educated at Oxford or Cambridge, though the fact was, that at those Universities the facilities for acquiring a knowledge of anatomy and medicine, as well as the mode of teaching, were far less than at many other places. The Licentiates, on the other hand, though degraded and insulted, had generally received a thorough education in all the branches; they were nevertheless accounted unworthy of a single post of honour in the College, and were generally excluded from Court and public appointments. Yet, by a recent return to parliament, the whole number of Fellows was 113, of whom 60 resided in London, while the Licentiates amounted to 274, of whom 142 are resident in the metropolis. But the College of Surgeons was still more illiberal, monopolizing, and exclusive. It was governed by a Council of 21, who were self-elected, and continued for life. The members of the commonalty were said to amount to 12,274; yet the bye-laws of the College excluded all members who were general practitioners from having any voice in the election of the Council. Counsellors could only be chosen from among the consulting, or pure surgeons, who amounted to about one hundred in London, and nearly the same number in the large towns; but the latter were not eligible. Persons, even among those, if known to be of liberal principles, were passed over, or could only take their seats by turning traitors to their principles, and as the reward of their apostacy. Then as to the Company of Apothecaries: what monstrous and absurd powers had

been granted to that trading company!—powers which were almost thrust upon them by the jealousies and impolicy of the Colleges of Surgeons and Physicians;—powers at which they themselves were greatly surprised;—powers of which they ought long ago to have been deprived. There were, it was true, some distinguished and amiable men in all those bodies, but in their corporate capacities were exhibited the natural and unfortunate effects of irresponsible powers, and the rottenness of the whole system, at present, of medical policy.

The address then referred to the changes which might be produced by the introduction of wholesome laws—by institutions properly elected and duly responsible—by due encouragement to real talent, &c. There would then be no exclusive teachers—no favourite schools, apart from real skill—the great hospitals would be purified from misgovernment and nepotism; there would be legal competition; honours and dignities would be accessible to all who deserved them; unqualified and illegal practitioners would be restrained; quackery would be put down, or greatly diminished; chemists and druggists would be duly registered, and not allowed to practise or prescribe. Then no poor-law commissioners, or their deputies, would be able to control a class of gentlemen, or introduce their pretended self-supporting clubs, or advertise for parochial surgeons, or for attending on the poor by tender. For the attainment of such objects the Association was formed, and now sought the co-operation of the whole profession. It was not intended to assume a literary or scientific character—that was deemed unnecessary; its intention was to confine itself chiefly to what was called the business of the profession. Its central situation, its contiguity to parliament, its vicinity to the Colleges, &c. rendered it remarkably adapted to that purpose. Meanwhile they wished to encourage the formation of Provincial Associations, who might contribute the requisite funds, collect evidence and information as to the existing evils, watch the workings of the Poor-Law Commissioners' schemes, forward petitions to parliament, &c. &c. The present period was remarkably favourable to such a union of liberal-minded men. The legislature and the government seemed quite willing to interfere. They had lately afforded assistance to a highly-talented member of the profession, who was also a member of the House of Commons (Mr. Wakley), in obtaining the Medical Witness Bill; and further assistance was promised him by Lord John Russell, in the formation of a committee for inquiring as to the medical relief afforded to the poor in the Unions. The great

principle had also been acknowledged in the new charter of the London University, that degrees could be conferred in the metropolis, and without reference to any religious opinions or distinctions.

The address then adverted to two provisions made in the code of laws; the first of which was the appointment of a Court of Honour, for the adjustment of any misunderstandings between members of the profession; and secondly, the formation of a benevolent fund, for the assistance of decayed members of the profession, and their widows and orphans. The address concluded by an urgent recommendation of the principles and objects of the Association, and a call upon all present for vigorous and persevering co-operation.

Mr. EALES, the Secretary, then read the laws and regulations of the Association.

Mr. POWELL proposed a resolution, to the effect that the meeting cordially approved of the objects and intentions of the Association; that it approved also of the code of laws which had been read, and recommended their adoption; and that the address delivered by the chairman be printed and distributed among members of the profession. He lamented that any jealousy or disunion should prevail amongst members of the medical profession, as that was one cause why their injuries had been so long perpetuated. They were not behind the professors of law, or of theology, in their aims to benefit their fellow men, and yet there was no body of men so generally disregarded. The fault he believed to be altogether their own. They had not stood before the public in their just position; they had been estimated as a set of tradesmen; and, though they laboured hard, they often lived poor and died in want. He was anxious they should assume their proper station. Efforts had sometimes been made, but, because of some pecuniary loss, individuals had been discouraged, and their privileges were not obtained. He sincerely wished that invidious distinctions were at an end, and that regard was had to talent, irrespective of minor considerations. Where there was real talent, it would be found out by the public, and they would patronize it. He adverted to some of the provisions made by the code of laws, and expressed his earnest expectation that, by unity of effort, they should succeed, however small their beginnings, to accomplish all they wished.

Mr. HOOPER dwelt on the importance of the Benevolent Fund, and lamented that the medical profession should be so far behind some of the most ordinary trades. He also adverted to the protection which they needed against unjust

prosecutions. Some might say, "Apply to the College of Surgeons to assist you;" but he believed that he might as well apply to St. Paul's Church Yard. He seconded the resolution with much pleasure.

Dr. MURRAY, of Lincoln's Inn, had been induced to desert the profession, because of the difficulties which lay in the road to eminence—because empirics and quacks had been allowed to practise with impunity—and because, in the corporate bodies, a system of exclusion and nepotism prevailed, by which persevering talent was often excluded from dignity and honour. That state of things had arisen out of the want of union in the profession, and from the want of proper laws to punish mere pretenders, and to protect men of real talent. The proposed Court of Honour would have very little to do if such an Association prospered. The profession would not then be subjected to insult from deputies and subalterns of poor-law commissioners, nor be treated as though they were errand boys to the poor. Then the quack, on one side, would not be able to thrust his drastic pill by hundreds down the throats of his wretched patients, nor would a fashionable quack, on the other hand, stand by the couch of expiring mortality prescribing the decillionth of chamomella. Had such an Association been formed some time ago, he should not have abandoned the profession of medicine for a profession which was far more arduous, but which presented no barrier to persevering industry. He wished to know whether one object of the Association would be to obtain a consolidation of the various laws in reference to the profession.

The CHAIRMAN, in reply, stated that such an object would be desirable, as well as the obtaining of new laws which should embrace the whole profession. He thought the profession might be divided into two general classes—the general practitioners, and the consulting practitioners.

Dr. J. JOHNSON agreed that talent ought to form the only distinction in the profession; but he thought that as such objections were urged against the College of Surgeons because they excluded general practitioners from their Council, it was equally objectionable on the part of the Association to exclude surgeons and physicians from its Council. Such exclusions were neither liberal nor politic, and though he was not personally affected by them, he could not but think it would be best that talent should be the qualification, irrespective of the particular line of practice.

The CHAIRMAN intimated that such an alteration ought to be introduced, if the Council saw fit, as he wished the Association to be placed on the broadest basis.

He should wish it to preserve the character of a representative society.

Dr. A. T. THOMSON thought they had not acted wisely to set out by vilifying any individual or corporate bodies. He was not prepared to oppose the formation of the Association, nor was he prepared to go the length of what had been stated in the address. He could not thus join to vilify public bodies.

The CHAIRMAN wished to know what body had been vilified.

Dr. THOMSON referred to what had been said about the Colleges. The Association ought to have been one of inquiry, and not of censure. Such inquiry might be productive of much good. Let not the Association plunge at once into a radical reform which can only do injury. He would fain become a member of the Association, but he could not support that portion of the address, and should be very sorry to see it published.

Mr. POWELL replied that inquiry was altogether unnecessary where abuses were so palpable. They might proceed in a namby-pamby course of inquiry, asking the corporate bodies to assist them—currying favour with the men who had been trampling upon them for twenty years. The abuses were well known, and he would have them seek relief where alone it could be rationally hoped for—namely, from the legislature of the country.

The CHAIRMAN disclaimed all intention to vilify any individuals or body of men, and deprecated all new inquiry, as altogether unnecessary.

Mr. BODY said that he had seceded from the Association on the very ground taken by Dr. Johnson. The address was most pleasing and delightful with that exception. He wished all distinctions to be done away with, he hated them, though he loved the men who bore them. The *dubs* would fain make them appear little men, that they might stride over them as so many Colossuses.

Mr. LUCAS contended that as pure surgeons laboured under grievances in common with general practitioners, the latter ought not to act so ungenerously to the former as to exclude them from this Association, and thereby aid in preventing them from obtaining redress.

Mr. WEBB said that he read the advertisements by which the present assembly was convened, and he determined upon appearing amongst them, and joining the Association. He had, however, been much displeased with the address which had been read, and had resolved to give a silent vote against it. Observations had since been made which had led him to the conclusion that it ought not to appear before the public that the general

practitioners unanimously concurred in the remarks which had been made against the three corporate bodies. The chairman had asked what those corporations had done for the profession; in reply to which he (Mr. W.) would simply answer, that to them they were indebted for nearly the whole of the medical literature which they possessed.

Mr. MEADE, in reply to Dr. Thomson's observations, contended that if they wanted reform in the medical profession, they must not have recourse to milk-and-water speeches regarding the Colleges. If they went before those institutions cringing, they would be spurned from their doors. No spirit should induce the general practitioners to dis sever themselves. The Colleges of Physicians and Surgeons could not withstand the united exertions of the medical profession. They had too long borne the oppressive measures of those chartered bodies. The Society of Apothecaries had opposed the most beneficial measures, and had done but little to raise the profession in the estimation of the public. They did not protect medical men from quacks,—on the contrary, they had shewn a disposition to prosecute members of the College rather than those who had no diploma whatever. He was sure that the address was sufficiently mild, and though he had listened to it with great attention, he had not heard any terms which could be construed into vilification. He was sure that on subsequent reflection Dr. Thomson would come to the conclusion that the terms which he (Dr. T.) had employed were unjustly severe. He trusted that this Association would go on and prosper.

Mr. LUCAS was desirous of knowing whether it was competent to an individual to offer a motion with regard to the rules.

The CHAIRMAN replied in the negative. They must remain unaltered till the meeting in March. He could assure Dr. Thomson that the address had not been drawn up in a hostile spirit. It was of no use to make inquiries: they knew that grievances did exist. What boon had the Society of Apothecaries conferred on the profession? Did they hear of the Society prosecuting a quack, or adopting any other measures calculated to promote the interests of the profession? With respect to the College of Surgeons, it had opposed the very act which had been lauded by Dr. Thomson—the Apothecaries' Act. It was disgraceful to place such power in a trading body: it ought to have been invested in the hands of those who were neither surgeons nor physicians. Had the power been conferred on stone-masons, they might have ap-

pointed proper examiners, and the profession would have derived an equal amount of benefit. It was not intended that such powers should fall on the Society of Apothecaries; and Dr. Burrows had stated, in his parliamentary evidence, that it was not prepared to receive them. There was so much illiberality in the body, that Dr. Burrows was obliged to withdraw himself from them. He was sorry to be compelled to make these remarks; but having grievances of which to complain, they would be fools if they did not seek their redress.

Dr. THOMSON felt called upon to state, that he had been very greatly misunderstood. He had stated that he had no objection to the Association; so far from it, he had attended the meeting with a view of supporting it, but he did not anticipate hearing the language which the address contained. It was his decided opinion that the mode of gaining the object which the Association had in view, was not that of couching their sentiments in strong terms; they ought to speak sincerely, but calmly. The language of the address would be injurious to the Association; he regretted it deeply, because he was anxious for the prosperity of the Association. It had been loosely stated that nothing but talent ought to regulate the opinion of the public; but the public had not shewn themselves accurate discriminators, and could not judge of the qualifications of medical practitioners without the aid of some other test than their own. He conceived that different ranks were still necessary in the profession.

The CHAIRMAN suggested that that question had not been mooted, and that talent was not sufficient for a medical man without proper qualifications.

Dr. THOMSON resumed: But who were to give them those qualifications? It was now vested in the three corporate bodies. He thought that the Society of Apothecaries had been unhandsomely treated; it had taken general practitioners from the low state in which they formerly stood, and made them scientific men. Dr. Thomson then contended that the medical profession had failed to reform itself, and that it was only in consequence of the present legal obligations to attain a certain degree of education, that general practitioners were better qualified than formerly. He admired the Association, and hoped that the assembly would speak of their grievances like sober-minded men.

Mr. CRISP argued, that if the public were unable to discern men of talent, they must be enlightened upon the subject.

The CHAIRMAN admitted that a great deal of good had been done by the Apo-

the carles' Act, but it was procured from the legislature by general practitioners themselves. He hoped that they would soon have one faculty of medicine existing in this country, having equal powers. It was the system of favouritism which had frequently prevented men of talent from succeeding in their profession. It was very rare for a Licentiate of the College of Physicians to become a court physician.

The resolution was then submitted to the meeting, and carried almost unanimously.

The CHAIRMAN hoped that Dr. Thomson would favour the Association with the aid of his talents.

Dr. THOMSON again expressed himself as friendly to the Association, but not to the address.

The CHAIRMAN, in reply to a question addressed to him by Mr. Glass, one of the pupils at the London University, stated that he saw no objection to pupils joining the Association.

Dr. HULL then moved a vote of thanks to the Chairman, which was carried by acclamation.

The CHAIRMAN briefly acknowledged the compliment, and the meeting separated.

OBSERVATIONS

ON

MR. SEARLE'S VIEWS RESPECTING THE TREATMENT OF INFLAMMATION.

To the Editor of the Medical Gazette.

SIR,

As Mr. Searle, of Kennington, has published a reply in your journal, to the observations which I some time ago made upon a paper of his, and as he seems to think I have acted disingenuously towards him, I beg that you will do me the favour to make room in your next number for the following rejoinder:—

Mr. Searle commences his reply, by saying that I have assumed a name which does not belong to me; that my proper name is "Conservative," because I complain "that long-cherished medical theories and modes of practice are (being) abandoned:" and surely, if I am on that account to be so denominated, I may take the liberty to retort, and to call Mr. Searle a "Radical," because he wishes, with the besom of destruction, to sweep away "theories and works of practice," which experience has led the members of the profession to cherish, and to raise in their stead "new-fangled doctrines." After bestowing upon me the appellation of Conservative, a

name to which I certainly have no objection, he says, that while I charge him with inconsistency I do not do so on my own; that I have opposed my words of the moment to facts which required many years to collect and investigate;" and then, in an indirect endeavour to show that I have no prejudices against Mr. Radley's mode of treating fractured bones, merely because it was new to me; but I beg to observe, if Mr. Searle will read the papers which I have published on that subject, in the *Medical Journal*, he will perceive that I have produced reasons in support of my opinion in favour of Mr. Radley's practice, and, that I have not opposed that general mode of treating fractured bones because it was new to me.

Mr. Searle then goes on to homeopathise and observes, that I should have been more like a true investigator, in denouncing that method of treating diseases as a "mania," I had first made trial of it; which is just as much as to say that no one should presume to try any medical novelty, however good it may appear to be, without first making trial of it. But how is homeopathy to be tried? It is certainly not in mild, trifling cases, because, in such cases, nature would perform the cures, and homeopathy receive the credit. And I beg to observe that the man who, in the case of a serious disease, did nothing more than prescribe a few ("billionth part of a grain") doses of common sulphur, or of some kind of medicine, in order that he might give homeopathy a trial, would soon find, by the fate of his patients, that he had committed an error, the recollection of which, unless his conscience be seared as with a hot iron, would embitter many of the moments of his future life.

Homeopathy is not quite so innocent in its nature as some persons imagine it to be. It is true that the extremely small doses of medicine which are administered cannot possibly of themselves do any harm; but the time which must necessarily be spent in administering them, and the delay in their effects, when other rational means ought, at the first opportunity, to have been had recourse to, cannot be overlooked. I therefore, notwithstanding Mr. Searle's opinion upon this point, do consider me a "true investigator," without first making experiments according to the infinitesimal system, may safely venture to denounce that thing which is so obviously absurd as homeopathy a "mania."

Mr. Searle next proceeds to charge me with his own "mania," and complains of my making too short a quotation in your paper, I have made it appear

actice, in the treatment of inflammatory diseases, to give food freely with one hand, and tartarized antimony with the other. He says, that tartarized antimony is so far from being a favourite remedy of his, that he has not recommended it to be taken internally, above ten times, within the last five years; and that he placed it at the end of a list of sedatives, because it is most frequently employed by the profession, and because he wished to make considerable strictures upon its use. But how could I, by reading the paper which he published in the *Lancet*, know that this was his intention? In that paper he does not, so far as I can see, even hint at any thing like a want of affection for tartarized antimony, excepting in cases where the arterial action is very high and strong; on the contrary, he never fails to name it first whenever he has occasion to recommend sedatives; even in the very quotation respecting which he thinks that I have dealt unfairly with him, he uses the following words:—"If considerable pyrexia attend subacute inflammation, it is evident that the predisposing cause, excitability, is earlier than the exciting cause, inflammation. Under these circumstances, febrile medicines, especially those of a sedative nature, as *tartarized antimony*, digitalis, &c. will, in general, produce a beneficial effect." Now, if Mr. Searle does not, by his language, mean to recommend tartarized antimony, what does he mean? But he says, let it be supposed that the case in the above quotation (which it appears I overlooked in my remarks upon his paper) had been really omitted by him, and that he had intended to recommend tartarized antimony only, (no matter whether he intended to recommend that medicine only or along with other things, he certainly did recommend it) that its use is restricted to cases in which considerable pyrexia attends subacute inflammation; that the patients who are subject to this form of pyrexia are either very young children, or persons of very delicate constitutions, who habitually take but little food, and who, when ill, manifest, in general, an insuperable aversion to it; that in children tartarized antimony is never given, nor even thought of; and therefore that there can be no inconsistency in giving that remedy, with the one hand, to very delicate persons, who have an aversion to food, because, as they cannot take nourishment, it is impossible to feed them freely with the other. Now all this appears to me to be merely an attempt to get out of difficulty through a loop-hole. But, admitting that the above explanation really did remove the inconsistency which Mr. Searle says I have disingenuously laid to

his charge, the practice, even then, is inconsistent, because it is in direct opposition to the "new-fangled" doctrine, which it is Mr. Searle's object to support.

But Mr. Searle does not, in every part of the paper which he has published in the *Lancet*, restrict the use of tartarized antimony to cases in which considerable pyrexia attends subacute inflammation, or, in other words, to very delicate persons, who cannot take food, as the following quotation from that paper will show:—

"The most direct method of removing inflammation is suggested by observing the manner in which it was produced. For instance, if a local phlegmasia be brought on by excitement of the general circulation, the use of an agent which, like *tartarized antimony*, depresses the general circulation, is the most direct method of counteracting the agency of the cause, and, as it were, of undoing the disease." Here there is no restriction to the use of tartarized antimony. No, the treatment is to be conducted, not according to the kind of inflammation, but according to its cause; and, therefore, although a patient may not be very delicate and weak, but on the contrary, strong and robust, if the disease under which he labours has been brought on by excitement of the general circulation, he is to be lowered by means of tartarized antimony; and I must observe, that the precepts of the "new-fangled doctrine," as far as regards the diet, are either, at the same time, to be followed or not. If they are not to be followed, the treatment is purely lowering. It is *antiphlogistic*; it is the very treatment which, if Mr. Searle means any thing by what he writes, it is his avowed object to oppose; and if they are to be followed, that is to say, if milk, beer, wine and water, eggs, or good broth, are at the same time to be "fearlessly administered," then the inconsistency, which he says I have disingenuously laid to his charge, becomes glaringly conspicuous. He must, therefore, either admit that he recommends, at one time, a practice which, at another, he condemns, or that I have not, after all, dealt unfairly with him, by making it appear to be his practice, in the treatment of inflammatory diseases, to give food freely with the one hand, and tartarized antimony with the other.

But, after reading the paper which Mr. Searle has published in the *Lancet*, from the beginning to the end, it will, I think, be very difficult for any one clearly to understand what, upon the whole, he really does mean. In one part of that paper he says, that "very high and strong arterial action cannot be controlled by sedative medicines, as tartarized antimony and digitalis; for

small doses of these medicines have no effect, while large doses occasion vomitings, which are often distressing and injurious to inflamed organs, and, unless they produce a uniform sedative effect, they are pernicious, as temporary depression of the circulation induces reaction, and thus defeats the object to be attained, and to nauseate the stomach, without subduing the disease, is worse than useless, as it renders the patient incapable of taking that *nutriment* which, *of itself alone*, would, "according to Mr. Searle's views, tend to diminish the pyrexia." But if nutriment, in a case of this kind, be all that is required, why speak of sedatives at all. It is not a sedative effect that is wished for, even if it could be produced. No; very high and arterial action is not, according to Mr. Searle's views, to be lowered; on the contrary, it is to be increased by nutriment, which, if "judiciously and fearlessly administered," will of itself alone tend to subdue the disease. Now this, it must be admitted, is strictly in accordance with the "new-fangled doctrine;" indeed, it is the new-fangled doctrine itself; but does it agree with the practice, which, as has been shown, Mr. Searle, in another part of the same paper, recommends, of giving tartarized antimony, with the view of "undoing the disease," by *lowering* increased arterial action? Let those who have read Mr. Searle's paper, and who clearly understand what, upon the whole, he really does mean, give the answer.

In this way I might go on, making quotations and animadversions upon them: but it is not necessary that I should do so, because the new-fangled doctrine and my remarks upon it are already before the members of the profession, who, of course, will judge of both for themselves. I shall therefore conclude, by saying, that although a staunch conservative, I am not hostile to what may be called the PHLOGISTIC plan of treating inflammatory diseases, because it is new; on the contrary, if it should so happen that I shall at some future period of my life, according to Mr. Searle's prediction, become convinced of the soundness of his views, I beg to assure him that I shall then, instead of indulging in disingenuous observations, at once abandon "my long-cherished" mode of practice, become his follower, and support, with zeal, the "new-fangled doctrine."—I have the honour to be, sir,

Your most obedient servant,
INVESTIGATOR.

Jan. 16, 1837.

MARYLEBONE SELF-SUPPORTING DISPENSARY.

DR. COPLAND'S RESIGNATION.

To the Editor of the Medical Gazette.

SIR,

YOUR number of the 7th instant contains a letter, signed "W. Eales," on the subject of self-supporting dispensaries. In this letter there is the following passage: "Dr. James Copland was the consulting physician of the present Marylebone Dispensary, and I have been authorized by him to tell my friends that he was compelled to withdraw his name from the institution in consequence of finding that really poor persons did not come to it, but that the patients were such as ought and could well afford to pay their medical men."—P. 558.

This statement is so contrary to fact, and contains such a serious charge of departure from the principles of the North West London Self-supporting Dispensary, that I have been directed by the Committee directly to contradict it.

Dr. Copland's letter of resignation states as his reason for that step, simply that his engagements prevent him from performing satisfactorily to himself the duties which devolve upon consulting physician to the Institution. In a letter written by Dr. Copland a few days since to one of the medical officers, he states, "as to the expression quoted by Mr. Eales, I could not have made use of that, inasmuch as I do not know, neither have I had an opportunity of knowing, whether the patients of the Self-supporting Dispensary are able or not to pay a medical man;" and although in this letter Dr. Copland expresses his belief that this and other kinds of medical charities are open to abuse, he admits that he has not seen any *one instance* during his connexion with the North West London Self-supporting Dispensary.

The rules of our Institution expressly declare that no person who shall appear to the Committee able to pay a medical attendant in the usual way, shall be admitted to the benefits of the Institution; many are refused on this account, as the means, condition, &c. of the applicants are investigated by a committee, before they are entered.

Further, whenever it is discovered that the means of a benefitted subscriber are beyond the limits of a scale fixed by the Committee, the name of that individual is erased from the books. Several instances of this kind have occurred; and the Committee will be always thankful to receive such information respecting the means of any of the subscribers as shall prevent any

abuse of the Institution, and may thus preclude it from interfering with the private practice of medical men. Those who now degrade themselves by publishing unfounded charges and gross misrepresentations of fact, should apply their attention to the actual working of the Institution; they would witness the benefits which it confers on the class relieved, and the honourable position in which it places medical practitioners; and if they should discover any instances of misapplication of the benefits of the Institution, by pointing them out, they would really do somewhat to increase its utility, and serve the interests of the medical profession.

Trusting that the same benevolent and candid disposition with which you have examined into the principles of Self-supporting Dispensaries will prompt you to insert in your next number this letter, in defence of the first institution of the kind successfully established in London,

I have the honour to be, sir,

Your obedient servant,

JOSEPH HUNT, *Secretary.*

N. W. L. Self-supporting Dispensary,
40, Manchester-St. Jan. 18, 1837.

SOCIETY OF APOTHECARIES AND THE NEW UNIVERSITY.

To the Editor of the Medical Gazette.

SIR,

IN your last publication but one, Scrutator lays it down as a positive rule that, because a gentleman does not apply for a mandamus, or to the Court of Assistants, in case he considers himself unjustly rejected, he must be conscious that he could not stand the test of a fair examination. In my opinion, sir, he jumps much too quickly to a conclusion. In the first place, there is a very general impression that the money which is to be paid on such a demand, is thrown away, inasmuch as the candidate is certain of a second rejection, with (of course) double disgrace. In the next place, human nature is not always composed of such tough material as to embolden a person to face the Court of Examiners with an exclamation such as this—"I am not afraid of any questions you may put to me, feeling assured that I cannot in justice be rejected." And where is the mind so comprehensive that does not shrink from an examination in the minutiae of all the sciences with which students are expected to be conversant?—not that I mean for it to be understood that the Examiners expect a very intimate knowledge of all the sciences; but I would ask any one to appeal to his own feelings, and say whether he would like to challenge such a body of men, who, taken collectively, no doubt, are well versed in

all the subjects of the examination? Scrutator also asserts that the University cannot in any way injure the cause of the Court of Apothecaries. Again, I think he is in error. I do not say it *will* injure them, for, on the one hand, there may be a reform in the Company, where it is needed. (and is there any public Institution that can be in such good humour with itself as to flatter itself with the idea that it needs no reform?) and on the other, the University may not in any way excel—but should it rise like a beacon to the medical world, as perfect as an institution of this kind can be, having profited by the errors of its rival, then, I think, no one will deny but that it may injure the business in Blackfriars. I have much admired, sir, the temperate manner in which you have treated this subject throughout, and I consider you are not less a friend to the interests of the students, ~~because~~ you do not rant and rave as if you had some great private interest in the matter. The longer I live, the more I am convinced that nothing of any real importance can be accomplished by such a course.

Your giving this insertion in your next, will gratify an admirer and constant reader,

JUSTITIA.

Plymouth, Jan. 17, 1837.

UNIVERSITY COLLEGE AND HOSPITAL.

DR. A. T. THOMSON.

To the Editor of the Medical Gazette.

SIR,

IT is, as you are I am sure aware, utterly impossible that any system of education can be perfect, or even beneficial to those engaged in its acquirement, unless a definite understanding exists between the teacher and those taught, as regards the period and manner of conveying instruction. An absence of this understanding, or, more properly, an unwillingness, on the part of one of the physicians of the North London Hospital, to fulfil his necessary and mutual compact, (for such it assuredly is,) exists in the person of Dr. Anthony Todd Thomson.

From the foundation of the hospital it has been declared, that clinical instruction and lectures would be regularly given both by physicians and surgeons; and, indeed, if we except that individual whose culpable negligence has called forth this public exposure, that pledge has been honestly and faithfully performed. But to continue, and to state the grounds on which Dr. A. T. Thomson is now brought before your notice—Is not his absence from the Hospital, during the days he should visit his patients, not an occasional but con-

stant occurrence? Is not the hour specified in the prospectuses as the period he goes round the wards, invariably passed before he makes his appearance at the Hospital door? And lastly, do not weeks constantly elapse without his delivering a clinical lecture, or even making a clinical remark in his passage around the wards? These questions, which must all be answered in the affirmative, require, indeed, no comment on my part; they may, however, not inaptly be placed as a set-off to those cases occurring, or said to occur, at other hospitals, by a cotemporary famed for his impartiality (?) but who at least shall be nameless.

I may, perhaps, shortly have occasion again to intrude upon your notice—not, I anticipate, as regards the hospital, but with some strictures on a portion of the medical department of the adjoining college. In reference to the chair of materia medica, assuredly there exists a something which, unless speedily removed, must soon effect such a change—revolution, shall I say?—as, in all possibility, will re-act in such a manner as to place the long continuance of that building, as a medical school, in perhaps the most precarious situation.

If, among the abundance of communications with which your journal weekly teems, the present can possibly find admittance, you will confer a favour on your obedient servant, and constant reader,

OBSERVER.

January 20, 1837.

[The writer has authenticated his letter.—ED. GAZ.]

NOTE FROM DR. HARGRAVE, OF DUBLIN.

To the Editor of the Medical Gazette.

SIR,
IN the London Med. and Surg. Journal, of the 31st ult. there is an article headed "News from Dublin:" being informed that it is attributed to me, I beg through the medium of the MEDICAL GAZETTE to state, that neither directly nor indirectly did I ever contribute any information whatever to that or any other journal, relative to the subject of the above communication.

To Drs. Graves and Stokes, and Mr. M. Collis, of the Meath Hospital, I am under deep and lasting obligations for the honourable and disinterested support given to me in the late election to fill the surgical vacancy in that institution.

I am, sir,

Your obedient servant,

W. HARGRAVE, M.B.

York Street, Dublin,
Jan. 14, 1837.

TREATMENT OF INTESTINAL FISTULÆ.

THE success attending the employment of the hot iron in the cure of artificial anus, already recommended by Dieffenbach, is confirmed by two cases related by Dr. Fingerhuth.

In both, abdominal inflammation, caused by violent blows, had been followed by external abscess, to which succeeded discharge of fecal matters. Various cauteries were employed to destroy the membranes lining the fistulæ, and to convert them into granulating surfaces, but without producing their complete obliteration. The fistulous openings, although somewhat diminished by imperfect granulations, showed no tendency to become closed. Cauterization was then adopted by means of an iron, corresponding in diameter to that of the fistulæ, and the temperature of which was scarcely elevated to that of red heat. Luxuriant granulations soon covered the cauterized parts, the fistulæ diminished, and the surfaces being again destroyed by a heated iron corresponding in size to the apertures which remained, they were eventually cured.—*Woch. für die ges. LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE XVIII.

PREMATURE AND RETARDED BIRTHS—

Occasions of inquiry respecting such births, in civil and criminal cases—Law of Legitimacy—Provisions of the Civil law—Ecclesiastical law—English law of legitimacy traced from the earliest period—Decisions in the English courts—French and Prussian law—Question of Prematurity—Grounds for medico-legal decision—Question of Retardation—Analogy in favour of the occurrence—Facts and cases in confirmation—Vagueness of the testimony in favour of a fixed limit—Conclusion of the argument—Peculiarities of the Gardner peerage case—Supplemental note.

ANOTHER view which we have to take of the births of children, is as they may be premature or retarded.

PREMATURE AND RETARDED BIRTHS.

Occasions of inquiry: 1. Prematurity.—The question of prematurity of birth may be raised in civil or criminal cases. A woman who has been married, perhaps no more than six or seven months, brings forth a child which appears to have attained its full uterine development; if this prove to be the case, upon a proper inspection by competent medical authority, the birth is premature and illegitimate.

Again, a woman is charged with concealment of the birth, and the presumption of her guilt is strengthened by the fact of her having made no preparation for her delivery; if it can be proved that

the birth was premature—that labour came on unexpectedly, at the seventh or eighth month—it will constitute a strong ground of defence; but such proof must be made out by medical evidence.

It is scarcely necessary to remind you of the remark I made in a former lecture, that premature births are not to be confounded with immature; the latter having reference solely to the condition of the foetus as to its development, while the former always implies that the infant has been born before the regular period, or the time usually allotted to a natural and lawful birth.

2. *Retardation.*—With respect to retardation, a woman may bring forth a child ten, eleven, or twelve months after her husband has died, or been separated from her. Is the offspring to be considered legitimate? In other words, are we to admit the plea of gestation having been protracted through grief, and depressing passions, or, indeed, through natural causes, where none of the former can be alleged?

How wide a field is opened for medico-legal inquiry, in the mooted of these questions, must be obvious; nor can it be less evident how much the tranquillity and honour of families depend upon the issue, as well as the reputation, and perhaps the safety, of individuals.

As the question of legitimate or illegitimate birth is closely connected with those of prematurity and retardation, we cannot proceed in a more orderly manner than in giving, previously to the discussion of the latter questions, a general account of the

Law of Legitimacy.

Civil law.—Our earliest arrangements for the legal determination of legitimacy were borrowed from the Roman law. “Pater is est quem nuptiæ demonstrant” was the comprehensive dictum of the Digest. But the demonstration of paternity created by marriage appears to have been only pre-

sumptive; for it was liable to be defeated upon proof of the husband's impotency or non-access.

One of the presumptions of non-access, or the absence of sexual intercourse between the husband and wife, was the abnormal duration of pregnancy. The period of gestation was very early fixed by the Romans. The Decemvirs determined that ten months constituted the utmost limits to which it could be protracted; and Justinian enacted that the child of a widow born in the eleventh month after her husband's decease, was illegitimate. It is further stated in the Digest, upon the authority of Hippocrates, that the period of gestation could not be less than seven months.

When the birth occurred between the seventh month and the eleventh month—that is, within the legitimate period—it was still allowable to dispute the legitimacy on the ground of non-access; evidence might be brought forward to disprove the occurrence of sexual intercourse between the husband and wife; but it was requisite that it should be very conclusive. Proof of the mother's adultery was not allowed to bastardize the child, as her guilt and his legitimacy were not inconsistent. Nor did the declaration of the husband or the wife against the legitimacy of the child, determine its bastardy. The fact was to be made out in the manner declared by law—namely, by proving impotence or non-access.

Ecclesiastical law.—The Canon law established a ground of legitimacy more definite, though not perhaps more easy of proof, than that just stated. In the Decretals the doctrine of access is overlooked, and the paternity of the child is made to depend on the answer to the question—by whom the mother conceived? Whether she resided with her husband or the adulterer, the child was illegitimate, if it could be proved to have been begotten in adultery. All circumstantial evidence that could possibly elucidate the fact, even the resemblance of the child to the adulterer or the husband, was admissible. The spirit of the Canon law would, indeed, almost seem to give the preference to the presumption of illegitimacy over that of the opposite state.

English law.—Neither the civil nor the canon law have ever expressly formed part of the law of England; though they have unquestionably had great influence in establishing principles for us, and in guiding the dictates of our earliest authorities.

Bracton, our oldest common law writer, expresses his definition of legitimacy almost in the very words of the Digest: "Legitimus hæres et filius est, quem nuptiæ demonstrant esse legitimum." But the

exceptions which he admits to this fundamental presumption have more latitude than either the civilians or churchmen allowed: they are these four—1, the impotence of the husband; 2, the absence of sexual intercourse at the date of the wife's conception; 3, the non-recognition of the child by the father; and, 4, any conclusive presumption arising from physical or moral causes that the child is the child of the adulterer.

The second ground of exception, it should be mentioned, is left in considerable obscurity: where the question could be raised, the result would depend on the period assigned for the duration of gestation; and the only notice of this important point in Bracton, is to be found in his account of the writ *de ventre inspiciendo*. When this writ was followed by a verdict of pregnancy, the female was placed in safe custody until the truth of the fact could be ascertained, or rather until there was no possibility of any future fruit of her alleged intercourse with her husband. The duration of her imprisonment was therefore necessarily bounded by the extreme limit of gestation, and what this was we are left to speculate, for Bracton only observes that in case of the pregnancy taking place, it may be "easily known whether the child is really or presumptively the child of the husband, or of another person, by computing the period between the mother's delivery and the death of her husband, as well as the period which she had assigned as the date of her conception. It is said, indeed, although others are of a contrary opinion, that a woman cannot exceed the period of gestation by one day, unless the child should have died in the womb, or have caused, by some extraordinary malformation, imminent danger to its parent." He admits elsewhere that if the mother's delivery be deferred to such a period as that "it is not probable that the child can have been begotten by the deceased husband, then the child is liable to be bastardized."

With reference to the fourth ground of exception authorized by Bracton, the proceedings connected with the execution of the writ *de ventre*, as already described, are sufficient proof of the admissibility of circumstantial evidence to controvert the presumption of legitimacy. The female whose pregnancy was the subject of inquiry underwent a strict examination by a jury of her own sex, and was obliged to answer a series of questions relative to the legitimacy of the child of which she could prove herself *ençainte*. These questions being prescribed by law, could not contain any irrelevant matter. They are not confined to the access, or even cohabitation, or virility of the husband, but assuming these

facts until they are disputed, they scrutinize the circumstances of the conception with such minuteness, as to shew the liability of the child to be bastardized as the result of an adulterous intercourse, although the mother was living with the husband at the date assigned for the conception, and under no disability of having conceived by him. The jury were to interrogate her "concerning the time of her conception—*how, when, and where*, it took place." If the mother ascribed her conception to an adulterer, and satisfied the jury, from the correspondence of time and place, of the truth of her statement, there seems no reason for doubting that the fact of bastardy would be treated like any other fact, and pronounced sufficiently proved. The questions would otherwise be nugatory.

Fleta, the copyist or condenser of Bracton, differs in no essential respect from his original. He is wholly silent on the period of gestation, and his only notice of the moral evidence by which the presumption in favour of legitimacy can be affected, is with reference to the recognition or non-recognition of the child.

When we look into the writings of Britton, another of our old English jurists, but comparatively more modern than either Bracton or Fleta (these by the way, wrote in Latin, while the former used the old Norman French), we find there something definite respecting the limits of gestation. It is Britton who has left us the most detailed account now extant of the process under the writ *de ventre inspiciendo*. We learn from him that forty weeks constituted the limit of the period during which the widow could be confined under this writ, and that the illegitimacy of the child was the inevitable result of the birth being protracted beyond that time. The heir was entitled to demand immediate possession of the fief upon the expiration of the forty weeks, and the right could not, upon any pretext, be any longer suspended.

On the other hand, if it proved that the pregnancy was real, and the birth occurred within the forty weeks, it did not follow *de facto* that the legitimacy was secured. The heir presumptive was still at liberty to aver that the child was begotten by an adulterer, or that the husband was absent long before its birth, or that its legitimacy was irreconcilable with any obvious or notorious circumstance: and if the heir could establish any one of these averments, it is expressly declared that he should not be deprived of the inheritance.

The earliest case of contested legitimacy on record, was decided five years after Britton's death—namely, Foxcroft's case, 10 Edward I. (1282). An infirm sickly man, confined to his bed, was married pri-

vately, and without the usual solemnities, to a woman who was already pregnant; in twelve weeks after marriage she gave birth to a son, but it was adjudged a bastard. The clandestine nature of the marriage, there can be little doubt, operated in determining the verdict: for the facts appear to have afforded ample ground for presuming a conspiracy, and thus constituted the strongest moral evidence that the child was illegitimate.

But the subsequent practice of the English courts was not in accordance with the spirit of Bracton, Fleta, and Britton. In the Year-Books we find the question of legitimacy once more cramped within very narrow limits. The fact of legitimacy was always presumed, unless it could be disproved by what was called special matter—viz. the husband's impotency, or his being out of the seas (*extra quatuor maria*) during the period of his wife's gestation. Chief Justice Thorpe decided in a case, 41 Edw. III. "that all matter was irrelevant which was only argumentative to prove the bastardy, for the party ought to conclude, and so bastard;" meaning by "conclude" to adduce the special matter of impotence or ultra-marine absence. And this decision was held binding through several successive reigns.

It may serve at once as an example of the partiality towards the civil law displayed by some of the judges, and a specimen of the language of the court on some of these trials, to mention that Judge Richill (7 Hen. IV.), in giving judgment in a case, used the extraordinary expression, more emphatic, certainly, than decorous—"Whoever bulls my cow, the calf is mine!"

The Year-Books are wholly silent as to the legal period of gestation. But Mr. Hargrave, the learned annotator of Coke Littleton, after diligently examining some contemporary sources of information, concludes, "that the law recognized forty weeks as the *usual* period of gestation, but *exercised a discretion* of allowing a longer period *where it was required by the opinion of physicians, or the circumstances of the case*." And this, perhaps, is as nearly as possible the actual state of our common law on the subject.

Lord Coke, with some inconsistency, has stated forty weeks to be the "*ultimum tempus pariendi*," while he refers to an authority which does not altogether warrant his statement: he is also at variance with some decisions of the courts in his own lifetime, which allowed forty weeks and ten or eleven days as the latest period. It is curious enough, that from this time until the year 1825 (an interval of nearly 200 years), the question was not again agitated in

this country. A case, *Foster v. Cook*, which occurred in Lord Thurlow's time, has been sometimes referred to as sanctioning a period of forty-three weeks; but it has been repudiated by some of the best authorities, and pronounced to be undeserving a place in our reports.

It was in the year 1825 that the proceedings on the claims to the Barony of Gardner took place before the House of Lords. I shall presently state the chief facts connected with that case, but may here mention, that it was attended with peculiar circumstances, in the highest degree interesting to the medical jurist. It was argued by the ablest counsel before the most learned law-lords of the day, and the testimony of sixteen accoucheurs, of the highest celebrity in London, was heard on the respective sides of the question. Fortunately we are possessed of an accurate report of the evidence, as well as of the opinions and judgments of their lordships. The whole has been published in one volume by Mr. Le Marchant, who was engaged as one of the counsel in the case; and to this gentleman's luminous preface I have to acknowledge myself much indebted for many of the preceding remarks.

In France.—The French law, previous to the Revolution, was very unsettled and vague in respect to decisions concerning legitimacy. Even so late as the year 1779, the parliament of Rouen recognized as legitimate a child born eleven calendar months and a day (nearly 48 weeks) after the death of the alleged father. But the Code Napoleon, the existing law of France, withholds the presumption of legitimacy when the child is born 300 days after the dissolution of the marriage, or when its birth has been concealed from the husband.

In Prussia.—It may be added that the Frederician code, without absolutely declaring children born in the *eleventh* month illegitimate, attaches such conditions to the proof of their legitimacy as make it almost unattainable.

Question of Prematurity.

1. *Where the infant is apparently full grown.*—The most usual form in which the question of prematurity is raised respecting a birth is, when a child, with all the appearance of having reached the limits of intra-uterine development, is born at a date too near the marriage day, or the return of the husband after a long absence. Suppose at six or seven months a married woman brings forth a child of the full size and perfect growth, there can be no room to doubt but that it is illegitimate; for a child of six or seven months has never been known to attain the development of nine. It is certain that at nine some infants are

still very small, and perhaps no larger than many at six or seven months; but still the difference is characteristic, and not to be mistaken: the nine months' child will always be found much farther advanced in growth; the colour and texture of the skin, the nails, the hair, the relative proportions of the trunk and limbs, together with other peculiarities already described*, will serve sufficiently to mark the distinction.

2. *Where it is immature.*—Should the infant present obvious appearances of being incompletely formed, the question of premature birth may yet be raised if the growth attained do not correspond with the time elapsed since marriage, or the return of the husband. We had an instance of this kind in the *fems de-musa* case, noticed in a preceding lecture, where, at five months and a half after marriage, an infant was brought forth, which was living, and not unlikely to continue to live. The difficulty was to shew, that, though immature, it was not premature (as considered in reference to the date of the marriage), nor, therefore, illegitimate. Medical evidence was eagerly sought, in order to decide the question; but the moral circumstances seem to have had more weight than the physical in removing the scandal.

Parturition habitually early.—There is a peculiarity in the nature of some women which ought not to be forgotten—namely, that of never going to their full time; bringing forth their children, for instance, in the seventh or eighth months. Some authors add what is still more remarkable, that this peculiarity is entailed on the females of certain families, who, without approaching the ninth month by several weeks, give birth to *mature* children. Of this, however, I must take leave to doubt, though we have it on the authority of La Motte. He tells us that he knew a young lady who, in the seventh month after marriage, brought forth a lively *mature* infant, to the great discomfiture of the husband, who began to suspect his wife's chastity; but when he again became a father, in seven months after a renewed intercourse, he was satisfied. Both these children, says La Motte, were vigorous and healthy; they grew up to man's estate, and became distinguished in the military profession. He adds, that this lady's daughters were also regularly confined in the seventh month. With every deference for such authority, I must still hesitate to believe that these seven months' children were not immature: on a careful inspection I doubt not it would have been perceived, that by the abridgment of their sojourn in the

* Lecture III. p. 69, ante.

they were perhaps not a little retarded in their growth and due progress.

about the full time.—The chief difficulty connected with the question of maturity is, perhaps, in reference to those births which anticipate the period by a week or two; for this brings us at once to the moot point whether or not there be a fixed and definite term for the human female, undisturbed by accidents, to bring forth the fruit of her womb? Or is there, as others assert, a time allowed by nature, so that marriage, which usually takes place at the end of nine calendar months, may sometimes a week or two earlier?

There is much reason for supposing that the latter position is correct; for in the case, even granting that the deviation may extend to two weeks, this would amount to a twentieth of the whole term,—a degree of deviation which, in relation to other periodical functions, would generally be admitted to be inconsiderable. Take, for example, menstruation: the law of nature seems to be that it should recur every twenty-eight days; but we do not know that the menses are not sometimes several days earlier in some women, while in others they arrive more tardily,—and this without apparent cause or disturbing cause? Puberty, which is an epoch which seems to be regulated by a law of nature, yet its approach is often premature,—often retarded. So with the capacity for bearing children, which the law of nature seems to cease with the end of this country about the age of twenty; many is lost some years earlier, and many several years later. And so with marriage, and other phenomena, which seem to be, and no doubt are in general, regulated to a regular law—a law, however, so far from being abrogated, seems confirmed by the exceptions.

The analogy of what is observed to take place in animals shall be presently noticed in speaking of retardation: it need not be added, in this part of our subject, that the weight of authority is decidedly in favour of the possibility of maturity being attained, and of a mature birth being effected, in some women a little earlier than in others. Haller mentions among the circumstances which are calculated to shorten the time of parturition—the size of the foetus, and its more active habits.

Where we may be called upon to give an opinion, we must have a regard to the possible operation of such circumstances; nor where the appearances of marriage seem complete, should we rashly conclude that the birth has been premature, because it has not occurred at the end

of the ninth month. Aristo, king of the Spartans, acted with an ignorant severity when he refused to recognize his son Demaratus, who was born somewhat sooner than the usual time after marriage.

Question of Retardation.

The observations already made as to what takes place in regard to other functions, will serve in some measure to show how births may be retarded, as well as precipitated, without abrogating what appears to be a law of nature.

Argument from analogy.—Every species of animals have their particular time allotted for bringing forth,—sheep at the end of the fifth month; mares on the completion of the eleventh; cows at the ninth complete; asses at the tenth; bears towards the end of the fourth; swine after five months; rabbits after one month; bitches after two; &c.: yet it is certain that owing to causes not readily to be assigned, deviations from the limits belonging to several of these species have been observed. Harvey, Heister, Wagner, and Professor Wildberg, have stated examples. M. Tessier, also, a distinguished member of the Academy of Sciences of Paris, directed his attention to this subject for many years, and found that even in those animals which are most carefully tended, and protected from disturbing influences, the varieties in the times of bringing forth have been very striking: thus—

Of 160 cows, the periods of gestation were observed to be as follow:—

Of 14	241—266 days.
3	270
50	270—280
68	280—290
20	300
5	308

Giving a difference of 67 days between the longest and shortest term.

Of 102 mares:—

3	311 days.
1	314
1	315
1	326
2	330
47	340—350
25	350—360
21	360—377
1	394

Giving 83 days difference between the extremes.

And similar results were observed with regard to sheep, rabbits, and other animals.

Now the argument thus deduced from analogy must be allowed to be very cogent; for if these facts be true, of domestic and savage animals which lead their lives subject to

so few causes that can tend to disturb the law of nature, how much more probable is it that woman is not limited to a certain fixed hour for bringing forth, when we consider her moral nature, and the influences to which, as a member of society, she is exposed.

Facts and cases.—But the question seems perfectly determinable by reference to facts, even if we had no analogies in its support. Let us state a few of these.

Dr. William Hunter, in a note communicated to Mr. Hargrave, and published by the latter in his *Coke Littleton*, says,—“The usual period is nine calendar months; but there is very commonly a difference of *one, two, or three weeks*. I have known a woman bear a living child in a perfectly natural way, *fourteen days* later than nine calendar months, and *believe* two women to have been delivered of a child alive, in a natural way, *above ten calendar months* from the hour of conception.”

The difficulty is in ascertaining the exact time of conception; women themselves, more especially married women, can rarely state it with precision, except under peculiar circumstances—such as a single act of sexual intercourse, effected clandestinely, or where the repetition is precluded; and it must be recollected that medical men in their cognizance of the history of any pregnancy, must derive their information as to the time of the occurrence of conception from the females themselves. In some well-authenticated instances this end of the chain has been laid hold of, and the fact of the period of gestation being occasionally protracted beyond the 39 weeks, or nine calendar months, has thus, we think, been put beyond all question.

M. Desormeaux has related a case which occurred under his own observation. “A lady, the mother of three children, became deranged after a severe fever. Her physician thought that pregnancy might have a beneficial effect on the mental disease, and permitted her husband to visit her, but with this restriction, that there should be an interval of three months between each visit, in order that, if conception took place, the risk of abortion from further intercourse might be avoided. The physician and attendants made an exact note of the time when the husband’s visit took place. As soon as symptoms of pregnancy began to appear, the visits were discontinued. The lady was closely watched all the time by her female attendants. She was delivered at the end of *nine calendar months and a fortnight*.”

Professor Burns mentions “ten calendar months and ten days dated from last menstruation” as the longest term he has met with.

Dr. Montgomery relates a case in which he had an opportunity of observing the period of gestation, where the time of conception was known with certainty. A lady who had been living at a watering place, through ill health, apart from her husband, for some months, received a visit from him on the 10th of November, 1831. He remained with her that night, but was obliged to return to town next day. The result of the visit was conception. She quickened on the 29th of January 1832, and was delivered of a healthy child on the 17th of August following, being exactly 280 days, or nine calendar months and a week, after conception.

In another case which occurred in Dr. Montgomery’s practice, the gestation was, at least, 41 weeks and a few days, and may have been 42½ or even 44; the difficulty of stating the term exactly being owing to the difficulty of deciding when the reckoning should begin; the date of the last appearance of the menses being alone certain.

The term of gestation was elicited incidentally in a seduction case which was tried at Lancaster some years ago. Sexual intercourse took place between the prosecutrix and the accused on the 8th of January: it was never repeated; and a child was born on the 18th of October following—that is to say, on the 284th day of pregnancy. The facts were positively sworn to—no observation was made by defendant’s council on the unusual length of the pregnancy—and a verdict for 50*l.* damages was returned*.

Dr. Dewees, of Philadelphia, states “that the husband of a lady, who was obliged to absent himself for many months in consequence of the embarrassment of his affairs, returned one night clandestinely, and his visit was only known to his wife, her mother, and the doctor (Dr. Dewees himself). The consequence of the visit was the impregnation of the wife; and she was delivered of a healthy child in *nine months and thirteen days*.”

In the medical evidence given in the Gardner Peerage case, several examples are mentioned by distinguished practitioners, of births having been retarded within their experience. Dr. Blundell declared that he knew one case in which conception certainly took place on the 9th of November, and delivery did not occur till the 23d of August following, making an interval of 287 days, or nine months and fourteen days. Dr. Merriman deposed that he had known cases to be extended to 285 days; in two or three instances to 296; in one to 303; and in one to 309, or nine months and thirty-six days.

* MEDICAL GAZETTE, vol. xi. p. 57.

Testimony as to a fixed limit.—When we ask, on the other side, for the evidence on which the doctrine of an invariable time of delivery is grounded, we find it adduced by a small number of authorities, who, having happened to be acquainted with some few cases in which they thought they could be sure of the date of conception, observed that the day of parturition coincided with their idea of a general law. But have we not a far greater number of cases, as just now shown, in which the delivery did not so coincide? And even if we had not this preponderance on the side of experience, to what does the testimony of the party now referred to amount, more than a certain degree of negative authority—*that* being assumed as not happening, which has not happened within their circle of observation? Let us see, however, whether, in the experience of these practitioners, the law was so very invariably obeyed.

Sir Charles M. Clarke, in his evidence in the Gardner case, states forty weeks to be the legitimate time, but only an average time, calculated from about the first suppression of the menses.

Dr. Blegborough, on the same occasion, considers thirty-nine weeks as the exact time, but forty the ultimatum: Mr. Pennington, that forty weeks is the regular time, but that it may be three or four days later.

Dr. Gooch maintains that thirty-nine weeks is the exact time, but that it may be a day or two earlier or a day or two later.

Dr. D. Davis also insists on thirty-nine weeks as the period, but inclines rather to one or two days less than beyond it.

And such was the whole of the evidence that could be procured in support of a precise time for parturition: three of the witnesses being for forty weeks, two for thirty-nine, the whole five admitting that there might be a certain excess, or defect, in the measure of the duration, and, in fact, differing among themselves to the extent of not less than *thirteen days!*

General inference.—From all that has been stated, it seems not unreasonable to conclude that there must be a certain extent of retardation admitted—perhaps even two, three, or four weeks, beyond the nine calendar months—particularly when the probability of the fact is borne out by good moral evidence. Some have thought that there should be also physical evidence in the appearance of the child, exhibiting signs of a more than ordinary degree of development, attained by its lengthened residence in the uterus. If such signs be visible, they will of course confirm the plea of protracted gestation; but it is not certain that a sojourn in the uterus continued

beyond the average period, is conducive to a corresponding growth; at all events, there are not sufficient grounds for our insisting on such proofs.

In extending our admission of the possibility of gestation being protracted to four weeks beyond nine months—that is, to 43 weeks, or 301 days—we go as far probably as any reasonable evidence can warrant us. When called on to admit cases of longer duration, we should require to have proof of the most convincing kind ere we give credit to alleged deviations which are confessedly so rare.

Claims to the barony of Gardner.—In the Gardner peerage case, the possibility of gestation being protracted to 311 days was a ground on which it was sought to establish the legitimacy of one of the claimants. The leading facts of the case were these:—Captain (afterwards Lord) Gardner, took leave of his wife on board ship, on the 30th of January, 1802, and sailed to the West Indies; whence he did not return until the 10th of July following. On the 8th of December Mrs. Gardner was delivered of a full-grown male child—that is, 311 days after the latest intercourse in which it could have been begotten by her husband. But there were other glaring facts in the case, tending to overthrow the legitimacy of this child. Mrs. Gardner was proved to have had, during her husband's absence, an adulterous intercourse with a Mr. Jadis, against whom a verdict upon that account for 1000*l.* damages was obtained by Captain Gardner. It moreover appeared, that when the Captain returned in the summer, Mrs. Gardner did not conceal her pregnancy, having hopes that the child might be born within a legitimate period: she even took measures for hastening parturition, or bringing on premature labour, by riding over the stones as much as possible in her carriage. But finding these means ineffectual, she pretended that it was a dropsy she laboured under, and contrived to be delivered secretly; nor was the child ever recognized by, or presented to, her husband. Yet this was Henry Fenton Jadis, *alias* Gardner, the counter-claimant of the peerage.

The remainder of the case is briefly told. Captain Gardner procured a divorce from his adulterous wife, succeeded to his father's title in 1808, and the year following married a lady by whom he had issue Alan Legge Gardner, described as his only son and lawful heir. In the year 1824, Alan Legge being 14 years of age, while Henry Fenton was one-and-twenty, petitioned the King to have his rights secured to him, by inscribing his name on the par-

liament roll as a minor peer. The petition of the claimant was referred to the Attorney-General (the present Lord Lyndhurst), by whom it was brought before the House of Lords. Counsel, as I have already mentioned, was heard on both sides; evidence, 1st, of the pedigree of the claimant, and, 2dly, of the illegitimacy of Henry Fenton Gardner, was adduced; and the matter ended in favour of the petitioner.

The illegitimacy of Henry Fenton Gardner was established, 1st, by evidence of his mother's adultery, and, 2dly, by evidence tending to show that the period of gestation was such as to render it improbable, if not impossible, that Captain Gardner could be his father.

It was on the latter of these points that the great body of medical evidence, already alluded to, was adduced. But it should be added, that the fact of illegitimacy was, after all, decided irrespectively of medical considerations. Henry Fenton was bastardized, not by reason of the time of his birth, but in consequence of his mother's adultery, and her concealment of the birth from her husband.

Still the proceedings in the Gardner case must be considered interesting, as having elicited so much evidence respecting the results of medical experience; and when we recollect that the main question is still open to discussion in any future case of a similar kind, the record of the proceedings must be deemed valuable. In Mr. Le Marchant's book you will find ample information on the subject; and I ought perhaps to add, that the discussions in some of our medical societies, soon after the publication of that work, and of which an account may be seen in the periodicals of the day*, will also prove not unworthy of your perusal.

I may take this opportunity of mentioning that it has been represented to me, that in noticing, in last lecture but one, the principal cases of transposition of the viscera, I omitted one which has been described by Dr. Lyons, of Brighton. I must be content to refer you to the case itself, in the 17th vol. of the *MEDICAL GAZETTE*, p. 514, where you will see that in the instance of a living female, of about twenty years of age, the heart was ascertained to be on the right side of the chest, and probably reversed, or "inverted." There are also some other circumstances connected with the case, which render it interesting.

* *MEDICAL GAZETTE*, vol. v. p. 337, *et seq.*

ON THE IDENTITY

OF THE

VIE PROBABLE AND VIE MOYENNE.

To the Editor of the Medical Gazette.

SIR,

A COLLECTION of the ages of 3,938,496 persons of both sexes, whose burials were registered during eighteen years (1813-1830), appears in the *Population Volumes* of the year 1831; and some notice of the result of 11,300 returns obtained from the parochial clergy of England and Wales for this purpose, was indispensable in the preface to those volumes.

Knowledge of the ages of the population then existing had been obtained in the enumeration of the year 1821, with a view to future use, when the registered burials should have accumulated to the year 1830 inclusive, the ages of the deceased having been first recorded in the year 1813, and 1821 being nearly a middle point of the entire eighteen years.

The increase of population during the life of man was the third element requisite for ascertaining an ultimate result; and this kind of inquiry had been pushed back to the year 1700, by the parish register investigation of 1801, under the authority of the first *Population Act*. These parish register returns were deemed of unquestionable authority from the year 1750, or for eighty years retrospectively from 1830; so that a small degree of uncertainty attached exclusively to those above that age, who are very few in a stationary population, and even fewer in England, where the population had doubled in the last 100 years.

A statement of the progressive increase of population in England was calculated from these materials, and appeared in the preface to the *Population Volumes* of 1801; and from the further lights afforded by subsequent population returns, aided by reference to the prices of corn, a more accurate calculation was made by Mr. Finlaison, and appears in the preface to the *Population Volumes* of 1831 [at p. xlv.]

From the combination of materials

thus obtained, Mr. Finlaison was enabled to calculate human mortality in England from nearly four millions of burials, in like manner as Mr. Milne from 1840 burials in the city of Carlisle; and it is proof of the extraordinary sagacity of the last-named calculator, that from such scanty materials he produced a table of the mortality of both sexes conjointly, which, from the age of 20, is always between the mortality of the two sexes as calculated by Mr. Finlaison, and differing very slightly from that of Mr. Finlaison's female sex between the fourth and the twentieth years of life.

Indispensable as is the knowledge of the increase of population, for the above purpose of deducing a law of mortality from national or local inquiries, such knowledge has not been obtained, except in Sweden, from the year 1749 (p. 396 of Milne), from which Mr. Milne has calculated Swedish mortality, in his elaborate tables iv. v. vi., at pp. 566-570 of his second volume.

But similar attention to the increase of population has not been customary among continental calculators, who usually satisfy themselves by inserting a conditional phrase, "provided the population is stationary," and do not the less proceed as if that supposition were well founded; which, however, probably never was true, and which certainly never has been proved to be true during the life of man, in any nation on earth.

The high reputation of such men as d'Ivernois, Quetelet, and Villermé, who have satisfied themselves thus easily, and in some instances produced strange results, rendered necessary a circumstantial proof of the effect of the ascertained increase of population in the English counties during thirty years (1801-1831); and for this purpose the *vie moyenne*, or expectation of life in the first year, was calculated on the burial returns of the recorded ages of the deceased in every county separately; the results proving that by thus disregarding the very different rates of increase, the *vie moyenne* of adjacent sections of the county of York seems to differ as 40 to 29; and in Lancashire, where the population increases most rapidly, the *vie moyenne*, so calculated, sinks to 25½. [See last page of the Population preface of 1831.]

Thus much was requisite in support of some passages in the said preface (p. xlvi.); and at the bottom of the preceding page, the *vie probable* (the age at which one-half are dead) is shewn to differ more widely in various counties (from 12 years to 38 years), from the same disturbing cause.

Further, it was remarkable, in pursuing these investigations, that a converging series of the *vie probable* and *vie moyenne* being constructed in the manner most consistent with fact, coincided in the several counties which indicated the smallest increase of population, or about 20 per cent. in the thirty years; so that it was impossible not to suspect that, at a lower rate of increase, the series of the *vie probable* and that of the *vie moyenne* would diverge from that point in the same ratio as they had actually converged from 100 to 20 per cent. increase, and that such series was governed by some analogy, which, if discovered, might be expected to throw new light on the general law of human mortality.

My suspicion or conjectural inference thus became worthy of practical investigation; and a scale was prepared accordingly, by assuming the series of the *vie probable* to converge at twice the rate of the *vie moyenne*; and in applying this combined scale to the several counties, many of them indicated a remarkable agreement with it.

How far this is true best appears by the following tabular scale applied to those counties which are placed in juxtaposition with it; and at the bottom of these counties is added Cornwall, the most healthy of our counties, where the actual *vie probable* surpasses the expected amount by 9½ years, the *vie moyenne* by 5 years, thus preserving the analogy of one to two. The Isle of Ely is also subjoined in contrast, as the least healthy part of England, where the *vie probable* is seen to fall short of the expected amount by 11 years; the *vie moyenne* by 3½ years; the latter as one to three, instead of one-half, the general rate. But exact conformity must not be expected, local healthfulness and its opposite not being the only causes by which it is liable to be disturbed. One of these causes is obvious, on consideration that the increase of population in the several counties is not known be-

yond the last thirty years; that is, not beyond the birth of two-thirds of the existing population (6528 in 10,000, according to the census of 1821), for nothing can be less consistent with fact than an equable ratio of the increase of population, a species of assumption which was carried back by King (one of the fathers of English statistics) to the Norman Conquest, and which has

not quite disappeared to the present time. It happens, indeed, that the increase of population in England and Wales having been 57 per cent. in thirty years (1801-1831), has arrived at that amount by an annual increment, differing very little at any time from 1·5 per cent., which gives the above total increase very accurately. But in the twenty-one years preceding 1810,

it is pretty well ascertained by parish register returns, that the actual increment (supposing it to have been uniform) was not much more than half the above, or about .85 per cent., the total increase from 1780 to 1801 having been between 17 and 18 per cent. Nor is there any thing like uniformity in the increment of the several counties in the three decennial periods between 1801 and 1831, as may be seen in the foregoing table, and is still more evident in Berkshire and Salop, which counties shew an equal increase of 33 per cent. in the thirty years; but the decennial increment of the former was 8, 12, 10; of the latter, 16, 6, 8,—a dissimilitude which could not but produce a discrepancy in the ages of those who have died, and of those who survive, in the two counties. This cause, in combination with salubrity or insalubrity (before noticed), permits us not to expect regular conformity to the combined scale, which yet agrees well enough with fact in the fifteen counties enumerated in the comparative view annexed to the scale of coincidence.

But why should the converging lines of the *vie probable* and *vie moyenne* meet at 19 or 20 per cent. increase of population? This bears the aspect of caprice or accident rather than of any established law, and if it be supposed (for the sake of argument) that such meeting or coincidence takes place in any given state of population, the quiescent state of NO MOVEMENT in advance or retreat, in progress or regress, bids fairest for preference; the very state, in fact, to which every respectable calculator endeavours to approximate in his apparatus for determining the true law of mortality, and the expectancy of life resulting from it; and as not one of these calculators has had in his thoughts any coincidence of the *vie probable* and the *vie moyenne*, it is fair to examine in support of such supposed coincidence the results at which calculation has actually arrived.

First in priority of date is the law of mortality and its results, as calculated by Mr. Milne from Swedish documents, after deducing the stationary from the actually progressive population (pp. 537—8). In his Table V., p. 569, both sexes are combined, and the expectation of life in the course of the first year of life is 36.12, to which adding half unity, ($36.12 + .5 = 36.62$) the average duration of life including the entire first year, is 36 years 32 weeks; and as the *vie probable* falls between 36 and 37

years, but nearer to the last, the coincidence is exact.

Mr. Milne's Carlisle Tables II. and III., pp. 564—5 may next be examined; and in these the expectation of life in the middle of the first year being 38.72, the average duration of life and annual mortality is 39 years 11 weeks. The *vie probable* (one-half dead) falls on the 41st year of life, so that the discrepancy is one year and three-quarters; but on this it may be remarked that Mr. Milne assumes the mortality of the first year of life very low, at 1539 in 10,000, (though he compensates for this in the next four years) whereas the Swedish mortality is 2015. A middle term may be found in the latest experience of Prussian mortality, which is rather less than 1700 in the first year of life, and if this were adopted Mr. Milne's radix would be increased to 10,161 ($1539 + 161 = 1700$) whereby the annual mortality and the *vie probable* would agree very well at the 40th year of life.

Mr. Finlaison, in his law of mortality, deduced from the population returns, (after correcting the effect of progressive increase) appears to have assumed the Prussian law of mortality for the first year of life, the registration of infant burial in England being defective from a known cause; and he assumes the mortality of males in the first year of life at 1826 in 10,000, their annual mortality at one in 40.5, and their *vie probable* at 43.5. Of his females, 1568 die in their first year; their annual mortality is one in 43.7, and their *vie probable* is 48.5. These differences of three years and five years respectively, are considerable, and adverse to my opinion of the identity of the rate of annual mortality with the *vie probable*: but, in truth, nothing certain can be predicated of the mortality of the first year; and if Mr. Finlaison had made use of the Swedish estimate of 2015 deaths in 10,000 born, his annual mortality of the combined sexes might have decreased from one in 42 to one in 39 or 40, and his *vie probable* have fallen from 46 to the same level: and I shall take the liberty to add here, in support of the superiority of the Swedish estimate, that burial registers seldom fail to err on the side of defect, and (if faithful) cannot be redundant.

After speaking thus freely of the ignorance under which we labour of the law of mortality of the first year of life, it is necessary to enter into explanation, lest this uncertainty should be supposed by the uninitiated to pervade

the whole science of what Laplace calls *statistiques vitales*, (the statistics of human life) where he announces that the annual mortality of any nation or society expresses the *vie moyenne* at birth, (the average duration of life) and leads to the amount of its population by an easy process, when once this multiplier of the burials is obtained. “But, continues he, “*La determination de ce facteur est le point le plus delicat;*”—this is a point of much difficulty; a difficulty which arises thus.

Insurances are seldom or never effected on the first years of life, and the nominees in government Tontine annuities are not numerous until they have fully reached the most advantageous expectation of life, which occurs from three to six years of age. Yet enough are enrolled in their first year for the purpose of calculation, if they were equably spread over that year; but the intensity of mortality is such at the commencement of human existence, that one-half of such deaths occur in the first three months; whence it happens that no Tontine annuitants can prudently be enrolled till after that period, nor indeed until the the greater portion of the first year has been by them survived. Thus the usual authority of enrolled lives here fails us, and we have no unquestionable basis on which to calculate the mortality of the first year of life, including as it does the first days, and weeks, and months after birth; and the difficulty stated by Laplace becomes

insuperable, unless by an exactness and severity of registration not easily enforced*.

But all this does not affect the calculated expectation of life beyond the age of infancy, because the series of such calculations travels downwards from the highest ages, which, indeed, are much exaggerated, only two individuals having been discovered by the collectors of authentic records of mortality in France, England, and Holland†, although the number of such recorded deaths is not less than 27,000, while common repute (as expressed by the relatives of the aged deceased) represents one in 2072 in England as having attained to that great age; in Sweden, (A D. 1754 — 1763), on the same kind of authority, the proportion is one in 1017; and Mr. Milne, in the Carlisle Table, seems to have assumed one in 909. Similar exaggeration in a minor degree is known to prevail from the age of 85, and may be detected, and even measured by comparison with recorded deaths which have occurred in sufficient number at and after that age. I add a Table to this effect, as it also affords general information of the expectancy of life in old age; but it is not to be inferred that the expectation of life in all preceding classes of age is materially affected by the overstated 5 or even 10 years in the ages of the very few individuals who, according to the most exaggerated statement, approach or surpass their hundredth year.

Age.	Mr. Finlaison. Gov. Annuitants.		Equitable Assurance	Average.	Mr. Finlaison. Parish Registers.		Carlisle Table.	Average.	Age.
	Males. Y.	Females. Y.	BothSexes Y.	Years and Decimal.	Males. Y.	Females. Y.	BothSexes Y.	Years and Dec. parts.	
70	9.22	10.99	8.99	9.73	8.94	9.66	9.18	9.26	70

90	1.95	2.83	2.16	2.31	3.42	3.70	3.28	3.47	90
95	1.18	1.55		1.36	3.05	3.20	3.53	3.26	95
100		.50		.25	2.78	2.72	2.28	2.59	100

* In Belgium, where the registration is said to be exemplary, 2250 die in their first year, which materially exceeds the Swedish registration of 102 by Finlaison.

† One individual of one hundred (sex uncertain) is recorded by Deparcieux; one female of 102 by Finlaison.

From the above Table it follows that, at 70, 75, and 80 years of age, selected lives (those of such persons as are concerned in money transactions) maintain a small and very probable superiority in expectation of life. At 85, exaggeration is barely perceptible in the balance slightly inclined to the other side. At 90, the exaggeration of common repute appears to be $1.16 = 60$ weeks, and the comparative expectation as 3 to 2. At 95, it is $1.90 = 99$ weeks, or as 7 to 3. At 100, it seems to be tenfold; but with such uncertainty, that it were well if all calculators assumed one male, two females in 10,000 to attain to their hundredth year.

After what has been said, and especially after what I have quoted from Laplace, showing the extreme difficulty of ascertaining the annual mortality in any nation or district, the writer of an article in the British Medical Almanack for 1837 will learn to moderate the severity of his remarks on the annual mortality ascribed to the several counties of England in more than one preface to the Population volumes of various dates. The mortality there stated is avowedly founded on results drawn from Parish Registers, and therefore liable not only to the variation which arises from every different ratio of increase of population in the several counties, but also to defect of registry, which in some places is considerable, in others trifling in amount. Why, then, was a fallacious statement admitted? Partly as popular information which could not be well be withheld; partly because the mortality of the same county at several periods is good authority for comparison with itself, and the prevalence of health or sickness in various seasons may safely be thus inferred. Beyond this, if the writer alluded to is a precise reasoner, let him never rely on annual mortality thus loosely alleged, until he has examined the authority on which it is founded, always mindful that a mere mortuary register is of no value for any general inference whatsoever.

I now return to my main argument founded on the tables inserted at a former part of this letter; and in the first place I must advert to the difficulty of inferring the coincidence and identity of annual mortality and *vie probable* in a stationary population from tables which seem to show that it takes place

where the increase has been 20 per cent. in 30 years. I am aware that I have to combat this objection, and I acknowledge that the first table seems to prove, on inspection, that the annual mortality would be 44, the *vie probable* 48, in case of stationary population.

In explanation of this, I must be permitted to observe, that the *vie moyenne* is reduced to about 25 in Lancashire, and that such decrease is caused by the disproportionate number of infants who are born, and consequently die, in a rapidly increasing population; whence it follows that a large omission in the registry of infant burials (of those infants who die before they are baptised) cannot but have the effect of pushing down the several counties from the position assigned to them by a calculation of the *vie moyenne* and *vie probable* founded on such defective registry of infant deaths; and I hope to convince the reader that this occurs in such a degree as to lessen the seeming duration of life in Rutland and North York to 38 years, and to render probable the alleged coincidence at the age of 40 or 41 years, in case of stationary population.

The annual mortality of England cannot differ materially from this last amount, which is expressed by 40.6 in the first table. Mr. Milne, in the Carlisle table, assigns 37.14 as the expectation of life, or *vie moyenne*, of the first year of human life, for the two sexes combined; Mr. Finlaison assigns to males 39.96, to females 43.20, expectation of life in the first year; and these three authorities average at 40.13. But it must not be forgotten that such *vie moyenne* is applicable not to the beginning, but to the middle, of the first year; so that annual mortality is always half a year more than the *vie moyenne*, as usually expressed, and the above average becomes 40.63, which is as near to the 40.6 of the tables as can be desired; and it is to be understood, that the tables are founded on this assumed coincidence, from which the *vie probable* and *vie moyenne* are made to diverge, so that at 57 per cent. increase of population, which is assignable to the whole of England and Wales, the tabular numbers agree with the fact of *vie probable* 25.4; *vie moyenne* 33. Nor will it be denied that what is accurately true of the whole, is fairly applicable as a test or measure whereby to discover the com-

parative effect of variously increased population in the several counties.

It may be worth while to remark, upon this appropriate occasion, that the *vie moyenne*, or expectation of life, does not, strictly speaking, apply to the middle of the year, but to the middle of the *mortality* of the year of which it is asserted; and this, in the first year of life, occurs at the end of the first three months, instead of six months. But such minutiae are of little value; nor does the attention bestowed on still-born infants (*morto-nes*) by some calculators, appear to me of importance: the entrance into life will always remain somewhat undetermined, and it is but lost labour to approach the mysteries of *Juno Lucina*; we must remember that in the commencement of the history of nations, as well of individual man, we are compelled to rest satisfied under some degree of obscurity. Nor is the other end of human life without its difficulties (already suggested), arising from the customary errors of common repute, and the paucity of authentic examples of extreme old age; whereas, in infant life, the calculator is embarrassed by the crowd who die and are forgotten.

Thus have I brought under notice the two sources of error which tend to represent the duration of human life beyond the truth; inasmuch as these forgotten infants would increase the number of individuals who have lived—that is, the *divisor* of the total years lived; and correction of the overcharged ages of individuals who survive 85, would diminish the number of years lived—that is, the *dividend*—and lessen the *quotient* or average duration of life accordingly. Thus, if ninety individuals lived 3600 years, the quotient would prove their duration of life (*vie moyenne*) to have been forty years. But if the divisor be increased to 100, and the dividend diminished to 3500, the quotient will show their duration of life not to have exceeded thirty-five years. This example is overcharged, but will explain the tendency of such corrections; nor must we forget that M. Quetelet calculates the mortality of infants in Belgium, in their first year, to be 2249 in 10,000*; so that the similar Prussian

mortality taken at 1700, and even the Swedish mortality at 2015 in 10,000, may be erroneous results, arising from defective registration of infant deaths. I say this to prove that the duration of life in England may possibly be over-rated at 40 years, and that if reduced to 38 years, my speculation in favour of the coincidence of the *vie probable* with the average duration of life, is not inconsistent with it.

1. I do not undertake to offer a positive demonstration in support of my opinion, but negatively I infer that it is well founded; for I have already shown in tabular form, the tendency of which cannot reasonably be disputed, that although the actual duration of life (*vie moyenne*) cannot really be affected by increase of population, the burial register in that case exhibits the short lives of infants in a proportion so preponderating, that in the given case of Lancashire (where the population has been increasing at the rate of 2.6 per cent. annually), human life seems to be shortened from 40 to 24 years; and a moiety of the recorded deaths (*vie probable*) to have approached within 12 years of the birth of these numerous infants. I have shown also that the population of England *collectively*, exhibits the same kind of result, an increase at the rate of 1.5 per cent. annually, having diminished the *vie moyenne* from 40 to 33 years, the *vie probable* from 40 to 25.4 years; and that the counties, generally speaking, show similar gradation of cause and effect. From this it follows that the converging series of *vie moyenne* and *vie probable* must somewhat meet; and we are authorized to assume that they cross each other, by the example of two Swiss villages, where the *vie moyenne* is found to be 45 years, and the *vie probable* 55 years*; the effect of decreasing population being probably augmented by the frequent migration of young Helvetians, and their returning home in mature age, when competence for retirement from busy life has been acquired elsewhere. Granting the opposite effects of increasing and of decreasing population, it is difficult to believe that the point of actual coinci-

life is not affected by his *L'Hypothèse d'une population stationnaire*, which invalidates all his calculations of mortality, except that of the first year of life.

* Sir Francis D'Ivernois, *Sur la Mortalité proportionnelle de quelques populations*, 1832.

* See M. Quetelet's "*Recherches sur la Population, &c. dans le Royaume des Pays-Bas*," p. 32 [100,000—77,507 = 22,493]; and it is proper to add, that the mortality of the first year of

dence is not also that of stationary population.

2. Further, I have to suggest, that as the mortality which occurs in every year of life settles the age of the dead definitively in that year, their *vie moyenne* and *vie probable* are no longer subject to doubt or calculation, and are evidently the same. By an equal division of the number of all the individuals who have died at various ages*, the particular age or middle point will be found, on either side of which a preponderance of years or age must ensue from the increase or decrease of population; and it is evident that the seeming duration of life, as well as the seeming age at which one-half die, will depart from the truth accordingly.

3. Next let us consider that the entire science which deduces the expectation of human life from the law of mortality, rests upon the average mortality which happens to all collectively: upon the ideal one MAN, who is thus made to represent his whole species; and that the *vie moyenne* and *vie probable* of any one man cannot possibly differ from each other in amount. All scientific attempts to ascertain the law of mortality from national or local mortuary registers, must first assume a stationary population, as an indispensable corrective; and they usually represent it by dividing this ideal MAN into 10,000 parts, and assigning to every age a due apportionment of vitality, as far as facts in the possession of the calculator authorize his conclusions. But the ideal MAN of stationary population seems to me still to retain unaltered his *vie moyenne* and *vie probable*; which, therefore, I hold to be identically the same.

4. The foregoing argument, I think, may be placed in another point of view. Every one, when first he reads or hears of any difference of amount between the average duration of life and the probable extent of life (the *vie moyenne* and *vie probable*), is incredulous, or at least perplexed, until he has tried the experiment on some accredited table of the law of mortality; after which he yields his assent to the result of his own calculation. But when his author tells him that such table is not accurate, unless on the hypothesis of stationary popu-

lation, and does not undertake to assure him that such has been the fact in the nation or city, or other society, from the mortuary register of which the said table has been compiled, the same author tacitly allows that the variation between the *vie moyenne* and *vie probable* may arise from want of certainty in this essential preliminary; a point which seems to need the following illustration.

The condition of stationary population requires that a new person, a new actor, shall be introduced upon the stage of life, whenever and as soon as a vacancy occurs by death of an established actor, whether old or young; and, speaking cumulatively, such deaths constitute the law of mortality in the drama of human life. Supposing no actor to have entered unless on vacancy, nor without notice taken, and regular enrolment of the fact, the *vie moyenne* and *vie probable* of any one of these enrolled actors could not but be identical, and therefore also of all the actors collectively, supposing the process of death and replacement not to have been disturbed by unauthorized absentees or intruders, who, by "their exits and their entrances," cannot but produce a perplexing variation in the average amount of life (*vie moyenne*), and its probable extent (*vie probable*); for it cannot be denied that a superfluity of unnoticed exits and entrances of the young (which represents an increasing population) will sink the *vie probable* towards non-age, and that a superfluity of exits of the old, not replaced by infants (which represents a decreasing population), will enhance it beyond its due amount. Hence it follows that a pretended law of mortality, calculated on a mere mortuary register, will seldom exhibit similitude of amount in the *vie moyenne* and *vie probable*, and conversely that a calculation founded on the mortality of a stationary population, will not fail to exhibit an identity of these amounts.

If the foregoing arguments shall be established on higher authority than mine, I think the symmetry of science will be improved, and its consistency established, by ascertaining that an identity of the *vie moyenne* and *vie probable* must occur, if the stationary population has been accurately assumed by the calculator, who will thus be enabled to verify his work. Such consistency or

* See Mr. Milne's process for settling the mortality of Sweden, had the population remained stationary, vol. II. p. 538.

it of the *vis moyenne* and *vis* would also tend to improve ice, by manifestly annulling the of all tables which purport to known duration of life to 'excepting always the table of ux), to Holland (excepting that boom), to Belgium, to Brau- (North Prussia), and to Swis- to Paris, to London, to Vienna, , to Brussels, and to Amster- these tables, indeed, cannot be uted, unless by authors who know that such calculations, on mortuary registers exclu- sign forty years as the dura- life in some of the counties of , but give no more than twenty- a to Lancashire; and that the *vis* of North York exceeds that of ork by eleven years, although ite and manner of living in two r portions of the same county e dissimilar: one of them, in- irth York), has acquired an in- f population of 21 per cent.; r (West York) of 73 per cent., commencement of the present . This brings cause and effect into view, and shows that in- inferring the average duration from mortuary registers, we rather attempt to estimate, and measure, the probable increase of on from the amount of difference the *vis moyenne* and *vis proba-* ed to the inhabitants of places ive produced tables of the ex- of life, constructed on the fal- sis of mortuary registers ex- . Science should not be dis- y referring to such documents ces to which they are quite in- , and even inapplicable, unless l with consideration of the in- population, as well as with the of existing population, and its tion into ages suitably to a lassification of corresponding ' registers on which reliance laced, or which have been sub- correction by analogy drawn l-ascertained facts.

I remain, sir,
ur most obedient servant,
JOHN RICKMAN.

CASES OF DISLOCATION OF THE HEAD OF THE FEMUR.

By THOS. WORMALD, Esq.

Demonstrator of Anatomy at St. Bartholomew's Hospital, &c. &c.

CASE I.—*Dislocation of the Head of the Femur downwards and backwards upon the Tuber Ischii.*

A MANIAC, who eluded the vigilance of his keepers, leaped from a third story window. Besides dislocating his thigh, he received other injury, of which he died in about an hour.

On examining the dislocated limb it was found considerably shortened and inverted, forming about half a right angle with the body. The shaft of the femur, crossing the symphysis pubis, was fixed immovably in this situation. As the patient was evidently sinking, no attempt was made at reduction.

Twelve hours after the death of the patient I commenced the dissection, by reflecting the gluteus maximus, when I found some of the fibres of the gluteus

FIG. 1.

A, head of the femur partly covered by B, the obturator internus, the tendinous fibres of which are separated from the muscular. C, the trochanter major concealing a great part of D, the acetabulum. E, the obturator externus crossing the neck of the femur. F, the lachiatric nerve pressed by the head of the femur against G, the tuber ischii. H, the gluteus medius, partly torn. I, the shaft of the femur much inverted, and crossing the symphysis pubis.

medius and minimus ruptured at their posterior edge. The pyriformis and the gemelli were also partially torn; but the four portions of the tendon of the obturator internus, which pass through the lesser ischiatic notch, were drawn out and separated from their connexions with the muscular fibres.

The head of the femur presented itself through a rent of the capsule, opposite to the upper part of the tuber ischii, above the quadratus, so that the great ischiatic nerve was somewhat displaced, and pressed against the tuber ischii.

In this case there was no difficulty in detecting the nature of the injury, as, besides the symptoms already described, the head of the femur could be felt resting on the tuber, covered by the outer edge of the glutæus maximus. If this patient had been in a condition to attempt reduction of the dislocation,—by fixing the pelvis and employing extension in the direction of the shaft of the bone, at the same time everting the limb, the head of the femur would have been brought opposite to the rent in the capsule, and would in all probability have been replaced in the acetabulum without greater difficulty than is usually experienced.

CASE II.—Dislocation of the Head of the Femur, with displacement of a portion of the Cotyloid Ligament, without Rupture of the Ligamentum Teres.

During the summer of 1829, a man about 40 years of age was admitted into St. Bartholomew's Hospital, labouring under pneumonia, of which he died. On examining his body, I observed that the left limb was somewhat everted, a little separated from the right, and shortened to the extent of half an inch. The head of the bone could be felt resting upon the ileum, between the acetabulum and the anterior inferior spine. On dissecting the muscles about the hip-joint, I found them in a healthy condition, excepting the obturator externus, which was small, of a brown colour, with fat deposited between its fibres, and the tendon was torn from its attachment to the femur. The head of the femur, surrounded by the capsular ligament, rested upon the ileum, between the acetabulum and the anterior inferior

spine, in a cavity which was then formed, partly by a preternatural growth of bone, and partly by what appeared to me to be the upper position of the original cotyloid ligament, which was probably displaced at the time of the accident. The original acetabulum was contracted and filled up by a fibrous substance. The ligamentum teres was entire, elongated, and flattened. The cartilage covering the head of the femur was in its natural condition, when it was in contact with the cavity in which it was lodged; but at the rotator aspect of the head of the bone, the cartilage was irregularly absorbed.

FIG. 2.

The head of the thigh bone (1) separated from the new cavity (2), which is bounded superiorly by the cotyloid ligament (3), and a preternatural growth of bone (4). The ligamentum teres (5) attached at one extremity to the head of the femur, at the other to each side of the notch of the acetabulum (6).

On inquiring into the history of this case, I ascertained, that when the subject was about fourteen years of age, he fell from a ladder, which produced the injury I have described. At the time of the accident, he experienced considerable pain, and for many months much difficulty in walking; but he eventually recovered, and at the time of the attack of inflammation, which destroyed him, he was actually engaged in carrying out beer for a publican who resided in Portugal-street.

In this case, at the time of the accident, the cotyloid ligament must have been partially separated, and probably

tion of the acetabulum was separated at the same time, which would have the head of the bone to occupy the situation which it maintained, with the ligamentum teres being necessarily ruptured. I cannot conceive it possible that any dislocation can take place without rupture of the ligamentum teres, provided it be of the usual kind, unless, indeed, a portion of the acetabulum be separated at the same time.

In all the other cases which come under my observation, where there has been fracture of the acetabulum with displacement of the head of the femur, the ligamentum teres has been destroyed. In this case, had any attempt been made to replace the head of the femur, perhaps much difficulty would have occurred in keeping it in its position, as in cases where the acetabulum has been fractured, although the head of the femur has been readily reduced, I have seen it impossible to maintain it in its proper position. This difficulty, I apprehend, will depend on the size of the portion of the acetabulum which is separated.

central mass, as there was scarcely any attendant hæmorrhage. A more particular examination, however, soon satisfied me as to its reality, and that, moreover, there existed an arm presentation. The liquor amnii had been discharged, and the os uteri was fully dilated. The operation of version was immediately attempted to be performed; but so firmly was the foetal body embraced by the uterus, that it would have been impossible to have effected it without risking the infliction of severe injury upon that organ.

In this most unenviable position I requested the co-operation of my experienced friend and neighbour, the late Mr. Bennett, senior, who also endeavoured to reach the feet of the child, but his efforts were alike ineffectual. He coincided with me in the opinion that the woman ought to be delivered as soon as it could be accomplished with safety, as it was evident that we were indebted for the absence of hæmorrhage to the unusual contractile power exerted by the uterus; and that any sudden or gradual diminution of its contractility, although it might facilitate the operation of turning, yet would in all probability give rise to a copious hæmorrhage, highly dangerous to the life of the patient; and as the want of pulsation in the umbilical cord demonstrated that the foetus no longer possessed vitality, it was therefore determined to eviscerate the chest and abdomen, according to the plan proposed by Douglas, of Dublin. The operation was immediately commenced, and after the necessary interval the delivery completed.

On the third day after the operation some symptoms of uterine inflammation were experienced, which soon yielded to venesection, leeching, fomentations, with the free exhibition of calomel, opium, and tartarized antimony, &c. At the expiration of seven or eight days all dangerous symptoms had disappeared. She perfectly recovered.

What renders this case so remarkable is the almost incredible fact, that there was no more hæmorrhage than in an ordinary parturition; and the deficiency of this formidable symptom can only be attributed to the powerful contraction which the uterus so beneficially exerted on the foetal body. It may be proper to remark, that the placenta was completely expelled from the vagina before

MIDWIFERY PRACTICE.

CENTRAL PRESENTATION AND EXPULSION.

to the Editor of the Medical Gazette.

SIR,

Your interesting communication of Mr. Phipps's case, inserted in the last number of your useful publication, relative to the retention of the placenta whilst the child remained *in utero*, brings to my recollection a similar case which occurred to me some time since, and which was attended with very extraordinary circumstances.

My attendance was requested on a woman named Phipps, about 38 years of age, a patient belonging to the East London Lying-in Institution, who was stated to have suffered the pains of parturition for some hours. On having recourse to the usual vaginal examination, a substance possessing the characteristic peculiarities of the placenta was discovered occupying the vagina, being at the same time entirely extra-uterine. I could hardly imagine it to be the pla-

the operation. It was nearly of the natural size.—I am, sir,

Your obedient servant,
EDWARD AUGUSTUS CORY,
M.R.C.S., Surgeon to the E. L. Lying in
Institution.

Cannon-Street Road.
St. George's East, Jan. 24, 1837.

EFFICACY OF CHLORINE IN SCARLATINA.

To the Editor of the Medical Gazette.

SIR,

OWING to the constant prevalence of scarlet fever, I am induced again to call the attention of the profession to the employment of chlorine in this too often fatal disease. A few years ago, when I resided at Bromley, in Kent, I published in the MEDICAL GAZETTE some very remarkable cases of scarlatina, treated by my partner, Mr. Williams, and myself, in which the chlorine appeared to be highly useful. Not having the GAZETTE by me, I cannot recollect the exact time, but I think it was in September, 1830. However, I will venture to trouble you again with the particulars of one very striking case. It was that of a young woman in the service of Lord Farnborough. She had been to visit her parents in the country. Whilst there, her brother and sister died of malignant scarlatina. Soon after her return to Bromley Hill she fell ill, and had the disease in its worst form. I visited her first on a Sunday evening: I gave her an emetic of ipecacuanha, and then directed her to take a glassful of the chlorine mixture as frequently as she could swallow it. Under this treatment the dangerous symptoms soon gave way, and on the Saturday following she was down stairs.

I could relate many more cases, in which equal success attended the use of this medicine. In short, out of a great number of patients who were at that time attacked by the disease, two only died, both in the village of Wickham, one an infant, the other a spoiled child, ten years old, whose parents would not allow either medicine or nourishment to be given against the child's inclination.

I hope I shall be excused for again

expressing a wish that medical men will give this medicine a fair trial, as other means so often prove ineffectual. My practice is to give, in the first place, an emetic of ipecacuanha, according to the age of the patient; to avoid active purgatives, which are injurious to children (particularly large doses of calomel); and then to give the chlorine as frequently as possible.

As it appears to me highly important that the chlorine should be well prepared, I will subjoin the formula for that which I use, which was given to me by Mr. Brown, surgeon, at Lewisham:—

R Potass. Oxymur. ʒij.; Acid. Mariat.,
Aquæ Distillat., aa. ʒij.

The acid and water to be mixed, and the oxymuriate dissolved in them. It is to be kept in a stopper bottle, in a dark place. Two drachms of this solution are to be put into half a pint of distilled water, to make the chlorine mixture.—I remain, sir,

Your obedient servant,
R. T. TAYNTON.

MEDICAL GAZETTE.

Saturday, January 28, 1837.

"Licet omnibus, licet etiam mihi, dignitates
Artis Medicæ tuere; potestas modo veniendi in
publicum sit, dicendi periculum non recuso."
CICERO.

THE BRITISH MEDICAL ASSO- CIATION.

THE proceedings of the "British Medical Association," at Exeter Hall, were at least satisfactory in this respect—they were perfectly explicit.

We confess that we had conceived, in the commencement, some favourable expectations of what might be the result of a well-ordered association of professional men, combined for their mutual advantage: and such, as we understood it, was the rallying principle announced by the managers of this scheme. But they have now thrown off

the mask; nor is it without some feeling of regret and disappointment that we discover what proves to be the real character of the society—a mere political union, distinguished by all the vices of ultra-radicalism.

This being the case, it cannot but be gratifying to every steady member of the profession, to learn that the meeting was what it deserved to be—a miserable failure. Notwithstanding all the previous announcements, and blowing of trumpets—and desperate were the blasts as the time approached—calling upon all persons from the highways and by-ways to be present, and upon all medical pupils to quit their studies and take a part in the proceedings—notwithstanding all these efforts made by interested parties for upwards of three weeks, nothing could be more wretched than the meeting. There were not above a hundred persons collected together, including about a dozen students; and among that hundred, not a soul was there of either name or note, unless we except Drs. J. Johnson, and Anthony Todd Thomson, both of whom felt called upon to protest against a part of the laws, involving a fundamental principle of the society.

Perhaps we should not exactly say that there was nobody else of note there, for we perceive that there were some of the figurants of the late Meade-and-Wakley meeting present; and though the latter eminent performer did not appear in person, he was amply represented in the spirit: the “address” was wholly Wakleyan. The *honourable* member for Finsbury shone conspicuous in every line of it; and it was evident that though for obvious reasons he did not choose to be of the *dramatis personæ* during the evening, the entertainment was got up chiefly under his direction, and that he had been at the rehearsal.

From the first, indeed, it has been notorious, how a certain number of the

general practitioners of the borough have been urged on by Wakley to their present awkward predicament: from a mere dinner-party they have been prompted by that worthy to erect themselves into an Association, and to assume a denomination as ridiculous as it is gratuitous. But who except the cajoled themselves, cannot see under whose ill-omened patronage they endeavour to flourish? Why was Exeter Hall left empty, when Wakley lifted his voice so loudly to fill it; when, week after week, the pages of his mercenary journal were devoted to the task of making any kind of muster? Why, simply *because* Wakley thus announced that he had bestowed upon the society his ominous protection: the mark of beast was thenceforth fixed upon it; and its doom is accordingly sealed.

Some eight or ten speakers, of whom, with the exceptions already made, no person has ever heard, engrossed the business of the meeting; and of these, some became dissentients and seceders as soon as the business was opened, and the principles of the *proposed* institution made known. This, however, was by no means extraordinary; for it was impossible that any reasonable man could listen to the farrago of unwarrantable language of which the address was composed, without being disgusted. Nor was the gross inconsistency of this precious document, backed up, as it professes to be, by a body of laws, less evident to any person not wholly blinded by prejudice: witness the abuse heaped on the College of Surgeons for the exclusive system followed in regard to their Council, while the very same principle is adopted by the new society, who are resolved that *their* Council shall consist of general practitioners only, to the exclusion of all physicians and surgeons!

“I hate the very name of a physician,” was the appropriate sentiment

uttered in the course of the evening by a Mr. Body (or Boddy), and we give the gentleman credit for speaking out his mind more candidly than several who went "about it, and about it," in a more cautious, but not less significant manner; though we think it rather insulting to the chairman himself—a Doctor!

Among the speakers, we observe that the Chairman was by far the most considerable, both as regards quantity of talk and boldness of assertion. We suppose it was for these qualities, though, under ordinary circumstances, they are not considered as either essential or becoming in the chairman of a meeting, that Dr. Webster was chosen to fill the office. By the way, this reminds us of another remarkable feature in the affair: here was a public meeting at which the whole medical profession was expected—or at least invited, to attend, in order to witness the first grand glorification of the "*British Medical Association*;" the meeting was held in the centre of the metropolis, where we need scarcely say there are many eminent and influential general practitioners, yet Dr. Webster had to be brought into town, from Dulwich, to preside! An active president he certainly was: he will excuse us, however, when we assure our readers that we never heard of him before, save through his after-dinner speech at the Tavern in the Borough. But to return to the Doctor's chairmanship. To notice even a tithe of the intrepid things uttered by Dr. Webster *ex cathedra*, would require time and space which we regret we cannot spare for such a purpose; but a specimen may be given without occupying much room.

The grievances of the Licentiates of the College of Physicians make a prime topic in the address: the "long degraded and insulted licentiates" are brought in compassion-

ately to adorn the rhetoric of the council; and the chairman frequently vents to the said grievances with more sympathy than consideration. Now we have no intention of defending, nor did we ever defend, the College system in regard to disabilities affecting the licentiates as a body: but a sense of truth and justice will not allow us to pass over at least one of the degradations which Dr. Webster supposes to attach to them. Among other things he asserted roundly and repeatedly, that it rarely falls to the lot of a licentiate to be a court physician. What is the fact? Let us enumerate. Sir Walter Farquhar was a licentiate and very influential court physician; Sir Gilbert Blane was also a physician in ordinary; Sir Matthew Tierney, Dr. Southey, Sir Charles Clarke, and Dr. Locock, are court physicians; and although some of them have since their appointment been made Fellows, yet, with the exception of Dr. Southey's case, this had nothing whatever to do with the circumstance of their being physicians to the court. Again, Sir William Knighton, the most confidential of all the attendants on Royalty in modern times, lived and died a licentiate. Dr. Clark, a licentiate, is physician to the Heiress presumptive of the throne; and in the person of Dr. J. Johnson, then in his presence, the chairman had an opportunity of beholding a licentiate who is one of the physicians to his present Majesty. So much for the doctrine of Dr. Webster, that a licentiate rarely becomes a court physician!

But what a mockery is it that sympathies should thus be professed for a learned body, by an association which refuses to let any of the supposed injured persons sit on their own council, and which disclaims for itself everything like a literary and scientific character. The fact were incredible that there should be such an association of members of

the profession attempted to be established in times like these, were it not distinctly avowed by the whole tenor of the proceedings, that the object of the new society is in no respect connected with the promotion of medical science, its purpose being purely political—to abolish all distinctions in the profession—to keep all on the same level, and prevent the possibility of any one exciting the envy of his disappointed neighbour by attaining pre-eminence. And this is what is called the *British Medical Association*,—as if it either had any one medical object in view calculated to produce general sympathy, or was ever likely to embrace even a considerable number, much less the great body, of practitioners throughout Great Britain.

We have ever been willing, and shall always be ready, to support any really liberal and general institution, based upon broad and manly principles; but we shall always repudiate every spurious off-shoot of radicalism that thrusts itself into notice by attempting to pull down whatever is respectable in the profession, and which, without drawing any line of distinction between the good and the bad, openly hugs and clings to those very vices which it condemns in others. More particularly shall we ever use our most strenuous endeavours to discountenance, and in every way to defeat, any project covertly supported by that party which got up the Meade-and-Wakley Crown and Anchor meeting of last year, and which bears, so conspicuously branded upon it, its appropriate motto—"Evil, be thou my good."

But whether we give it the benefit of our opposition or not, it is satisfactory to know, from the issue of all previous schemes projected by the same party, that a *Wakleian Medical Association* always carries within it the elements of its own destruction. It will in the end

share the fate of the *Wakleian College of Medicine*, and those other politico-medical humbugs originating in the same source, all of which have vanished into oblivion through the gate of disrepute and infamy. The founder, of course, cares for none of those things, so as his purpose of the hour is answered.

INSPECTOR OF ANATOMY.

WE understand that the Inspectorship of Anatomy for Scotland, previously held by Dr. Craigie, has been conferred on Dr. James Somerville, in addition to that for England.

ROYAL INSTITUTION.

Friday, Jan. 20, 1837.

Dr. Faraday on a new General Law of Matter.

THE series of evening meetings for the season was opened by Dr. Faraday, who delivered a very interesting lecture. He chose for his subject the new general principle of matter demonstrated recently by Mosotti. It had been long suspected by some of the most enlightened minds, that there was still some great general law to be discovered, which should embrace and explain all the known phenomena of gravitation, the attraction and repulsion of the particles of solids and fluids, and electricity. Dr. Roget, among others, above ten years since distinctly alluded to the probable existence of such a law, and shewed how, on a certain hypothesis, the powers in existence, which seemed independent of each other, might be all comprehended under one general force. This, however, which had till lately been only conjectured, has now been proved by a train of strict mathematical reasoning, similar to that by which Newton demonstrated his principle of gravitation. Dr. Faraday, in order to render Mosotti's discovery intelligible, performed a beautiful set of experiments, in which the phenomena of gravitation, attraction, and repulsion, and electricity, which seemed most independent of each other, were exhibited, and in the end pointed out how they were all reconciled by Mosotti's law. We cannot undertake here to give more than a general idea of the new principle, which even the accomplished lecturer himself scarcely hoped to render thoroughly understood. It supposes the existence of a universal ether, which pervades all bodies, and constitutes

around every particle of matter a distinct atmosphere.

All the physiological phenomena with which we are acquainted can be accounted for by the properties of this etherial medium, and so comprehensive are they, that gravitation sinks into a mere fraction of the newly-discovered force. Another consequence of the new law will be to abolish the theory of two fluids being concerned in electrical appearances. Franklin's hypothesis of a single fluid will doubtless henceforward be generally adopted, to the exclusion of the other assumption so strenuously supported by Poisson, Bequerel, and the French school generally.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

MR. EABLE, PRESIDENT, IN THE CHAIR.

Tuesday, January 24, 1837.

THE discussion of Dr. Weatherhead's paper (see the analysis of it in our last number) constituted the business of the evening.

Dr. JOHNSON commenced by complimenting the author on the ingenuity with which he had woven a handsome tissue or web from yarns that had been spun by various hands. He quite agreed with Dr. W. in giving the nervous system the initiative in the production of inflammation; but he thought that Dr. W. had offered no proofs of such precedence. The author had taken the old definition of inflammation for his text,—*rubor*, *calor*, *dolor*, *tumor*,—deducing each succeeding phenomenon from its predecessor. Dr. J. contended that the very first link in the chain was omitted, and that that link was just as capable of demonstration as any of the others. The *rubor*, with which Dr. W.'s definition commenced, offered no necessary proof of connexion with the nervous phenomena, since a dead tissue might be reddened, and even healed, by the injection of blood or wax. He would take Dr. W.'s two illustrations—blushing and blistering. Was it not perfectly evident that a mental impression—nay, an excitement of the general vascular system, preceded the capillary injection of the cheeks? But the second illustration would be still more in point. Let Dr. W., or any other gentleman, paint a patch on his arm with the liquor lyttæ, and watch the phenomena. Long before any redness appeared, there would be a *morbid sensation* in the part, after which the usual signs of vascular action would take place. The

first phenomenon of inflammation, he contended, whether induced by art or arising spontaneously, was *læsis sensibilitatis*,—a phenomenon as well ascertained, and as clearly demonstrable, as any of the other four links in the chain of phlogosis. Gout, erysipelas—every kind of inflammation—presented the *læsis sensibilitatis* before any of the vascular signs occurred. So far he hoped he had assisted in establishing Dr. Weatherhead's theory; but there were other points in which he (Dr. J.) could not agree.

Dr. W. believed that *suppuration* was a mere separation or infiltration of the serum, and other constituents of the blood, into the inflamed part, and that the pus was formed by a combination of its elements out of the vessels. Dr. W. supported this doctrine by an experiment of Van Swieten, who observed that the discharge from an ulcerated surface was clear at first, and took on the puriform appearance subsequently. He also noticed cow-pox, chicken-pox, and small-pox, where the vesicles at first contained clear lymph, which was afterwards changed into pus; but he relied much on the analogy of the secretions, all of which he (Dr. W.) maintained were mere separations or filtrations from the blood, the elementary constituents of each secretion combining afterwards, and forming bile, semen, &c. &c.

To this doctrine Dr. JOHNSON demurred. He contended that suppuration was a specific action of the inflamed vessels, and that pus was formed by the vessels and deposited in the part—not a fortuitous combination of elements. In support of the same argument, Dr. W. indeed leaned upon the fact, that pus was sometimes found in the blood, and that bile was secreted by the kidney. Dr. J. denied that pus had been found in the blood, except where there had been phlebitis, and consequently where there was secretion of purulent matter. He (Dr. J.) also denied that bile was ever found in the blood, or in the urine, except this fluid was resorbed from the liver, as in jaundice, hepatic obstructions, &c. The resorbed fluid was carried into the torrent of the circulation, and thrown off, not secreted by the kidneys.

Dr. WEATHERHEAD replied, and observed that he purposely avoided any reference to the phenomena of the nervous system, as the first step of inflammation, because we knew very little of the nervous or initiatory movements in inflammation, or other morbid processes. He still defended his position, that suppuration was a separation, not a secretion; and that what are called secretions and excretions, as bile, urine, &c., are mere filtering of their elements from the glands, which filterings combine

and form the peculiar secretions in the different reservoirs.

Mr. MACILWAIN spoke at great length, and generally against the doctrines laid down in the puper. He particularly denied that there was any proof of a stasis in the blood of an inflamed part; but, on the contrary, that there was every reason to suppose the blood was accelerated, rather than retarded, in the phlogosed structures.

Mr. HOWSHIP advocated the doctrine of stasis in the vessels during inflammation, and referred to the experiments of Drs. Philip and Hastings, on the circulation in a frog's foot, when irritated and inflamed.

Dr. CLENDINNING made some remarks on the diminished velocity of the blood in inflamed parts.

Mr. EARLE, in noticing Dr. Johnson's observation respecting *lesio sensibilitatis*, referred to a paper of his in the *Medico-Chirurgical Transactions*, vol. 7; and concluded the discussion by relating a case which occurred in his practice at St. Bartholomew's Hospital. To this we may have another opportunity of recurring.

CLINICAL LECTURES,

DELIVERED AT THE

MEATH HOSPITAL AND COUNTY OF DUBLIN INFIRMARY,

During the Session 1836-7.

BY PROFESSOR GRAVES.

LECTURE IV.

General treatment of Fever—Dietetic management—The Starvation system may produce Organic Disease—Proper Food for Fever Patients and Convalescents—Allaying of thirst—Sedatives—Eupergesfacients—Efficacy of Green Tea in a case of Narcotism—Flagellation effectual in a case of Poisoning with Opium.

At my last lecture I spoke of some preparatory steps which should be taken before you enter on the treatment of a case of fever. I stated that one of the most essential requisites was a good nurse; that you can readily find persons to undertake this office in every family, but that it is rare to meet with any individual among the patient's relatives properly qualified to discharge so important a duty. There is a vast difference between readiness to undertake and ability to perform. Some persons are always a-doing, but never do, right; always attempting, but never successful. There are many nurses who are

extremely attentive, but inexpert and injudicious, and their ill-judged attentions are frequently prejudicial to the patient. A fever-nurse has a vast deal in her power: if an enema is to be administered, the patient will be much less disturbed and annoyed than if it were given by an unskilful person. The mere handling of a patient—the moving of him from one bed to another—the simple act of giving him medicine or drink—the changing of his sheets and linen—the dressing of his blisters—and a thousand other offices, can be performed with advantage only by an experienced nurse. Always bear in mind that it is of the utmost importance to economize the patient's strength in fever. The very act of lifting him up, or moving him from one side to another, tends to produce exhaustion. In the advanced stages of fever, the services of a properly qualified nurse are inestimable. Then there is the moral management of the patient, and this is an office which no one can undertake unless qualified by experience, and a correct knowledge of the habits of persons labouring under such forms of disease. Every one admits the value of moral superintendence in the treatment of the insane. Now there are very few patients who are not in a state analogous to insanity, for a longer or shorter period, during the course of typhus fever. There is a necessity for moral management in fever as well as in insanity, and this is understood only by an experienced nurse. Friends or relatives are seldom found capable of discharging this office. If they chance to discover from the physician's remarks, or questions, the weak points of the patient's case, they generally contrive to let him know them in some way or other. If the patient is restless, for instance, the ill-judged anxiety of his friends will most certainly prevent him from sleeping. They steal softly to his bed, draw the curtains, move the candle so as to make the light fall on his eyes, and wake him perhaps at the moment he is settling down to rest. If he happens to take an opiate, and that they are aware of the nature of his medicine, they inform him of it, and his anxiety for sleep, conjoined with their inquiries, prevent its due operation. Hence, when you prescribe an opiate, you should not, in many cases, say any thing about it; and it should not be administered in such a way as to lead the patient or his friends to expect any decided benefit from it. It is only where I have to deal with prudent persons that I break through my rule of concealing both the nature of the medicine and the results which I expect from its operation. One of the best ways of giving an opiate is to

administer it in the form of an enema. The patient's attention is then turned away from the consideration of loss of rest—he supposes that the enema is to act on his bowels, and in expecting a motion he drops asleep. You will often, too, succeed in producing sleep in this way, where you would fail in bringing it on by an opiate administered by the mouth. Another recommendation attached to this mode of exhibiting opiates, is, that it can be employed in cases of delirium, where the patient obstinately refuses to swallow any kind of medicine. Let me give you here another caution. Do not let the patient know the situation or extent of his danger, however you may feel bound to act in reference to these matters towards his relatives or friends. If you apprehend mischief in the brain, do not commence by examining the head, or putting your questions in such a manner as to lead him to suspect the seat and nature of the affection. The same remark may be applied to the examination of the thorax and abdomen.

At my last lecture I endeavoured to impress upon you the fact that there can be no doubt that persons have been occasionally starved to death in fever; and laid before you some remarkable facts connected with the influence of protracted abstinence on the general system, as well as on the brain and digestive tube. I endeavoured to show that long continued denial or want of food generates symptoms bearing a very close resemblance to those which are observed in the worst forms of typhus. Pain of the stomach, epigastric tenderness, thirst, vomiting, determination of blood to the brain, suffusion of the eyes, headache, sleeplessness, and finally furious delirium, are the symptoms of protracted abstinence; and to these we may add, tendency to putrefaction of the animal tissues, chiefly shown by the spontaneous occurrence of gangrene of the lungs. It has been shown by M. Guislain, physician to the hospital for the insane, at Gand, that, in many instances, gangrene of the lungs has occurred in insane patients who have obstinately refused to take food. Out of thirteen patients who died of inanition, nine had gangrene of the lungs. You perceive, then, that starvation may give rise to symptoms of gastric disease, to symptoms of cerebral derangement, and to mortification of the pulmonary tissue. It is not, therefore, wrong to suppose that when a system of rigorous abstinence has been observed in fever, and when food has been too long withheld, because, forsooth, the patient does not call for it, and because his natural sensibilities are blunted and impaired—it is not, I say, unreasonable to

suppose that gastric, cerebral, and pulmonary symptoms may supervene, analogous to those which result from actual starvation.

An attentive consideration of the foregoing arguments has led me, in the treatment of long fevers, to adopt the advice of a country physician of great shrewdness, who advised me never to let my patients die of starvation. If I have more success than others in the treatment of fever, I think it is owing in a great degree to the adoption of this advice. I must, however, observe, that great discrimination is required in the choice of food. Although you will not let your patients starve, do not fall into the opposite extreme: you must take care not to overload the stomach. When this is done, gastro-enteric irritation, tympanitis, inflammation, and exasperated febrile action, are the consequences. I have witnessed many instances of the danger of repletion in febrile diseases. A case of this kind occurred some time back in this hospital, in a boy who was recovering from peritonitis. In another case, in private practice, an incautious indulgence in the use of animal food was followed by a fatal result. A young lady ate some beef-steak, contrary to my orders, at an early period of convalescence from fever, relapsed almost immediately, and died in thirty-six hours. Food must be given with great care and judgment, particularly in the beginning of fever. For the first three or four days, particularly if the patient is young and robust, water, weak barley-water, and whey, will be sufficient. After this I am in the habit of beginning with some mild nutriment. What I generally give is some well-boiled gruel, made of groats, and flavoured, if there be no tendency to diarrhoea, with sugar and a small quantity of lemon-juice. The ordinary oatmeal gruel does not answer sufficiently well for this purpose, for it is apt to produce griping and diarrhoea, symptoms which are extremely disagreeable in the commencement of fever, and which often lead to others of a more troublesome and formidable character. I am also much in the habit of giving a little thin panado, morning and evening, during the latter part of the first, and the beginning of the middle, stage of fever. A small slice of bread is slightly toasted, and boiling water is poured on a table-spoonful of the crumbs, in sufficient quantity to make a thin panado, of which the patient takes a table-spoonful two or three times a day. It may be flavoured with a very small quantity of lemon-juice and sugar, if there is no tendency to diarrhoea; but where this exists, or where you are administering mercurials, I think you should

Be cautious in the use of acids. Although medical men are of late rather less cautious in giving acids during the use of mercurials, I think the practice is not entirely devoid of danger, and I think our predecessors were right in withholding them under such circumstances. You will begin, then, on the third, fourth, or fifth day, according to circumstances, with a little gruel; and after two or three days you may add a little panado, giving, as I have already observed, a spoonful of either every third hour. As the fever advances you may add some mild animal jelly or broth; and one of the best kinds of nutriment in the middle and latter stages of fever, is chicken-broth. I do not speak here of chicken-water; I mean good and well-made chicken-broth. Give this, but give it in small quantities, and with great caution, at first. Watch the effects of the few first spoonfuls; it may act injuriously, and you should give it up, at least for some time, if it produces any bad effects. If it brings on heaviness, sickness of stomach, flushing of the face, excitement of pulse, and increased feverishness, give it up, and return for some time to the gruel and panado. You can try it again in a day or two; for although your patient does not bear it to-day, he may to-morrow, or the day after; and it is a most fortunate circumstance when it agrees with him, for, as I have already observed, it is the best kind of nutriment you can give in the middle and latter stages of fever. The best mode of giving it is to make the patient take a table-spoonful of it regularly every third hour, or oftener if necessary.

Recollecting the tendency to diarrhoea and intestinal irritation in fever, you will be extremely cautious in allowing your patient the use of fruits. Indulging patients in the use of grapes and oranges is a very popular, but, in my mind, very hazardous and improper custom. I have on many occasions seen persons injured by fruits of this description. Stewed and roasted apples are still more dangerous; they are apt to produce tormina, flatulence, diarrhoea, and intestinal inflammation. All acid or raw fruits have a tendency to produce irritation of the stomach and bowels, and should be avoided altogether, or very sparingly used.

One general observation as to the administration of food and nutriment in fever. All kinds of food and nutriment should be given by day, and the patient should, if possible, be restricted to the use of fluids by night. The natural habit is to take food by day and not by night, and in sickness, as well as in health, we should observe the natural habits of the economy. With respect to drinks, the mildest, of

course, should be preferred: on this point most persons are generally agreed, and it will be unnecessary for me to detain you with any particular observations. There is one error, however, which is very frequently committed in the use of drinks in fever: patients are generally allowed to drink too much. It may be urged that they have a strong desire for fluids; but they should not be gratified in every thing they wish for. They labour under a constant state of nervous irritation and restlessness, and will beg of you to do twenty different things to relieve their immediate feelings; but it would be just as improper to give them large quantities of drink every time they desire or call for it, as to indulge them in any momentary whim which may be the offspring of their disordered and changeable fancy. The continued swilling of even the most innocent fluids will bring on heaviness of stomach, nausea, pain, and flatulence, and predisposes to congestion and intestinal irritation. From the mere ingestion of a large quantity of the simplest fluid, you will frequently see well-marked symptoms of gastric irritation arise during the course of fever. This is not a picture drawn from imagination; I have witnessed it on many occasions during the course of my practice. It is extremely painful, indeed, to be obliged to refuse drink to a patient labouring under intense thirst; but you should never allow them to take a large quantity of fluid at a time: you should impress upon them the danger attendant on such a practice, and tell them that a spoonful or two, swallowed slowly, allays thirst more effectually than drinking a pint at a time. The sensation of thirst, as you all know, is almost entirely confined to the fauces and upper part of the pharynx, and it is as much relieved by a small quantity swallowed slowly and gradually, as by a large quantity gulped down at once.

Besides the simple fluids, there are other drinks required in fever. Beer, ale, porter, wine, tea, and coffee, are also frequently used in the treatment of fever, and are of the utmost value when employed on appropriate occasions; they are adjuvants of the highest importance in the dietetic management of fever, and it will require some time to explain the rules by which you should be guided in their administration. I shall therefore speak of them according to the indications with which they are given; and, first, of tea and coffee. You are aware that we are constantly in the habit of ordering medicines to diminish nervous irritation or restlessness, and to procure sleep; but I believe we are not much in the habit of prescribing remedies which produce an opposite state of the system. We give sedatives and narcotics

to tranquillize, to produce a species of exhaustion of the mental faculties, and to bring on sleep; and I do not see any reason why we should not also administer expergeficients, or remedies calculated to maintain intellectual activity, and keep the patient awake. Among those remedies which are most frequently employed for the latter purpose, are tea and coffee. You have lately seen the use we made of an infusion of green tea, in a case of narcotism which occurred in the fever ward. A man who was in the latter stage of fever, and labouring under great nervous excitement and total loss of sleep, was ordered an opiate enema, after we had tried various other means without success. During the course of the evening he got twelve drops of black drop, with two ounces of mucilage of starch, in the form of enema, and soon after fell into a sound sleep. When we came next morning and inquired after him, every thing was reported to have gone on well; the opiate enema had answered the purpose completely, and the man was still sleeping soundly. We found, however, on a more accurate examination, that he was in a kind of lethargic state, and could scarcely be roused. When addressed in a loud tone of voice, he raised himself heavily and slowly, half opened his eyes, gave a brief answer to our questions, and then, leaning back on his pillow, dropped asleep. Observe here the danger connected with this state. He was in an advanced stage of fever, had been restless and sleepless, and had suddenly passed to an opposite state. The rapidity with which coma had supervened on sleeplessness, and the danger of fatal congestion of the brain coming on, gave me considerable alarm. There was no use, however, in thinking of what had been done; the man's state called for prompt and decided measures, and we proceeded at once to attack the symptoms of our own creation. One of the gentlemen went down and got some green tea, of which he made a strong infusion, and administered a strong dose of it to the patient. This had the desired effect; the symptoms of coma gradually disappeared, and when I came to see him in the afternoon, he was quite out of danger. Green tea was first introduced here as an expergeficient in the treatment of coma by Dr. Edward Percival, son to Dr. Percival, of Manchester; and some years back he read a paper at a meeting of the College of Physicians, in which he brought forward several cases of coma and stupor, in which green tea had produced the most favourable effects. On the continent they generally use strong coffee for the same purpose. Whether these beverages produce this effect by their influence on the circulation, or on the

nervous system, I am not prepared to say; but there cannot be a doubt of their efficacy and value in many cases of this description; and I am frequently in the habit of using both with this intention.

While on the subject of expergeficients, I shall beg leave to read for you a very curious case from the 13th number of the Boston Medical and Surgical Journal, in which an expergeficient of a less agreeable character was employed to rouse a patient from the lethargic stupor brought on by a large dose of laudanum. There are some transatlantic peculiarities of expression in the detail of this case, but I have no doubt of its being correct. It is entitled "a case of successful treatment by flagellation, where a large dose of laudanum had been taken." And the author, Dr. Joseph Barrett, of Middletown, Connecticut, proceeds as follows:—

"Tincture of opium is not unfrequently resorted to for destructive purposes. It is also, unfortunately, and too frequently, taken by mistake, and proves fatal before efficient means can be adopted to counteract its deleterious effects on the system. I am induced, therefore, to offer a short statement of a case of poisoning with laudanum that fell under my care several years since, for the following reasons: first, the success that attended the mode pursued, and secondly, from not having met with any such means recorded, to my knowledge*, either in works on medicine, or in treatises on poisons."

Observe, gentlemen, it is not I that am speaking here, but Dr. Barrett, of Middletown, Connecticut.

"In the year 1822, February 23d, I was called on to see Mr. Wright Harris, (this was in the state of New York) who had intentionally taken a large dose of laudanum for the purpose of destroying himself. He had committed this act during his absence from home, under circumstances which it is not important to relate. Much time, about three hours, was therefore lost, before any effectual measures could be adopted for his relief. His case, as I found him, appeared to be altogether hopeless. Before my arrival, emetics and various drinks had been tried, besides frictions, and constant, though ineffectual attempts, had been made to irritate the œsophagus by feathers. All these means had failed, and the patient was in such a profound sopor, that apparently nothing but warmth remained to indicate that life had not already become extinct. The quantity of laudanum taken was ascertained to be one ounce and a half. The case appearing so desperate, justified me

* This practice, though not generally adopted, has been recommended by several authors in Europe.

in the course of treatment which I was, under existing circumstances, then obliged to adopt.

"Internal remedies having entirely failed, there was no chance left but for high external excitements. I therefore determined to use vigorous measures. I commenced with flagellations, using long, pliant, fresh twigs to the palms of the hands and soles of the feet. These were briskly applied, and in a short time gave indications of uneasiness and pain. This treatment was unremittingly pursued till the man spoke and complained of being pained by the whipping, when this severe appliance was relaxed; but on so doing, he instantly sunk into a profound stupor, from which he was again only roused by the severity of the whipping. It required the aid of a number of men to take turns in the flagellation, as well as to support and walk him about; for a cessation of the use of the rods was followed by instantaneous stupor. After about six or eight hours under this course, the stupor was lessened, and the severity of the flagellation mitigated; but as the case required constant high excitement, it was still repeated at intervals, till eventually the exercise of walking was sufficient to keep him awake. This was in about twelve hours from the commencing with the flagellation. He afterwards experienced but little inconvenience from his hands and feet, and was perfectly restored in a few days to his usual health. I would here state that the first proposal made by me to adopt flagellation as the only hope, was objected to by the persons present, from its carrying with it the semblance of unkindness towards what was regarded by them as a corpse; and it was not till the appliance of the rods by myself, in the first instance, that I obtained the aid of those present; but as soon as the patient began to move, and at last spoke, they took hold with alacrity, and by dividing themselves into relief parties, they very cheerfully, and rather amusingly, kept up the castigation so long as the state of the patient required it at their hands. He by no means seemed to relish this harsh proceeding, and in return gave his attendants several severe blows. If while lifting his arm to give a blow, the flagellation was then entirely suspended, the arm would instantly sink powerless; to such a degree had the effects of the narcotic drug prevailed over the nervous system, that nothing but the torture of the rods could rouse him. On his recovery, it was said that the man's wife was highly satisfied with this remedial course, which was believed to have a good effect upon his subsequent conduct."

UNIVERSITY COLLEGE, AND NORTH LONDON HOSPITAL.

DR. A. T. THOMSON.

[BEING in possession of OBSERVER's name and address, immediately on receiving Mr. Lewis's letter we communicated it to our correspondent, and are thus enabled to lay both reply and rejoinder before the reader. For ourselves, we know nothing of the circumstances; but with regard to the respective writers, we may state that while both are pupils of the hospital, OBSERVER is the senior, and may be considered as having had more experience than Mr. Lewis.—ED. GAZ.]

To the Editor of the Medical Gazette.

SIR,

A FRIEND pointed out to me a letter in your last number, concerning Dr. A. T. Thomson, which, as containing so many absurdities and falsehoods, I hardly think it worth while to reply to; nor, in fact, should I do so, were it not for the sake of those who may be strangers to Dr. Thomson and the North London Hospital. Holding the office that I do, in the hospital, under Dr. T., I am likely to have proper information on the subject. I doubt if your correspondent "Observer" has. I will take the charges *seriatim*, and reply to them in as few words as possible. The first question—Is not his absence (Dr. Thomson's) from the hospital during the days he should visit his patients, not an occasional, but a constant occurrence? is *totally false*.—During the last three months that I have been Dr. Thomson's clinical clerk, he certainly has not absented himself more than twice. I know of only once, and that was caused by illness.

Query 2d—Is not the hour specified in the prospectuses as the periods he goes round the wards invariably passed before he makes his appearance at the hospital door?—Dr. Thomson is quite as regular in his attendance as any of the other physicians or surgeons of this or any other hospital.

Query 3d—Do not weeks constantly elapse without his delivering a clinical lecture, or even making a clinical remark in his passage round the wards?—Except during the last two or three weeks, when the Doctor has been very much engaged on account of the prevailing epidemic.

Dr. Thomson gives clinical lectures whenever there are cases interesting enough for subjects of clinical instruction.

Hoping you will be impartial enough to

insert the above, in answer to "Observer,"
I am, sir, yours, &c.

W. A. LEWIS, *Clinical Clerk.*

P.S.—It would only be a waste of time to reply to the concluding sentences of "Observer's" letter. He may be sure that the council of the University College are fully competent to judge of the talent and value of the professors, without any hints from anonymous correspondents.

To the Editor of the Medical Gazette.

SIR,

CONSIDERING the prodigious excitement under which Mr. Lewis apparently laboured at the time he penned a reply to my former communication, it will doubtless appear bold on my part entering the arena of discussion, having for my antagonist one in such a fearful state of anger as is evidently the clinical clerk to Dr. Thomson, at the North London Hospital.

With regard to the first statement contained in my last letter, and which Mr. Lewis has so unhesitatingly branded with the epithet "totally false," I can only regret that I am unable to bring forward *dates* in support of the accusation; I must therefore trust to assertion, a mode at all times extremely objectionable, yet in the present instance unavoidable—though one, however, in the case before us, in which I have the honour(?) of Mr. Lewis's company. I have frequently waited at the hospital for Dr. Thomson's arrival until half past twelve (his time for attendance, as posted on the notice-board, being twelve), and after this have left, presuming, as I think, on just grounds, that the patients, such a time having elapsed, would scarcely on that day receive the benefit of his presence.

Mr. Lewis's mode of exculpating Dr. Thomson from the second charge is as novel as it is unsatisfactory. I have yet to learn that the circumstance of some individuals being guilty of sins of omission, is a plea which may be adduced as a means of justification for others. I shall dismiss, therefore, this second part, by merely stating that his reply is but a tacit acknowledgment of the justice of my complaint.

He (Mr. L.) then goes on to state, "that Dr. T. gives clinical lectures whenever there are cases interesting enough for subjects of clinical instruction." Now this, although doubtlessly meant as a justification of Dr. T., is, nevertheless, the unkindest cut of all. Can Mr. Lewis have so taken leave of his senses, as not to perceive that in that very answer, he more than implies a doubt of the Doctor's capabilities. Does he not know that a person possessed of only moderate professional

ability is able to throw the charm of interest over even the most simple case of disease? And does he not, moreover, know that such is peculiarly the duty of the hospital physician? for in his future career the student will not find the bulk of his practice made up by cases "interesting enough," as Mr. L. terms them, but by those which would apparently, in his opinion, be devoid of all points of professional attraction. You will instantly perceive, by Mr. Lewis's own assertion, that the Doctor has not lectured for two or three weeks, thus proving most indubitably, as I stated, that weeks elapse without his delivering a clinical lecture, and thus bearing me out in the last assertion. As regards the reason Mr. L. has assigned for this omission, I can only state that I have no knowledge of the extent of Dr. Thomson's private practice, more particularly during those periods when the influenza is prevalent; but I may remark that Dr. Elliotson, Messrs. Cooper and Liston, have all found time to continue uninterruptedly their clinical instructions. In reference to this subject also, I may remark, that to my certain knowledge, on account of the smallness of the hospital, many persons are every week refused admittance; but that among those who make application, those only are selected whose cases, either from severity or rareness of occurrence, present points of interest. With these the wards are always full, as you, Mr. Editor, may convince yourself, by paying any day a visit to the establishment. How, then, does it happen that the cases under Dr. Thomson's care are so devoid of interest, or of practical importance? Perhaps Mr. Lewis can enlighten us on this point. Should he think this communication requires an answer, I shall have much pleasure in again replying to him, but trust he will then bring forward facts; as it is, his present letter has more than once brought to my recollection the old fable—

"Parturit montes, nascetur ridiculus mus."

I am, Mr. Editor, as before,

Your obedient servant,

OBSERVER.

University College,
Jan. 26, 1837.

P.S.—As Mr. Lewis has favoured your readers with a postscript, I can only follow a good example. I shall, perhaps, ere long send you a few quotations from my note-book, taken in Dr. Thomson's ward, as well as some specimens of inconsistency and absurdity extracted from a work on *Materia Medica and Therapeutics*, by A. T. Thomson, M.D. Professor in the University College.

LIST OF DRUGS, ON SALE IN THE ENGLISH MARKET,

With their Prices and several Duties.

(From the Official Returns up to Tuesday, Jan. 24, 1837.)

THE LATE DR. MACNISH.

THIS well-known author died at Glasgow, on the 26th of last month, in the 35th year of his age. The first of his writings which brought him into notice, were the able papers which he contributed to Blackwood, with the signature of "A Modern Pythagorean." But the works which have rendered his name widely celebrated, have been the Anatomy of Drunkenness and the Philosophy of Sleep. These have gone through several editions, both here and in America, and have been translated into most of the continental languages.

His premature death is the more to be regretted, as every successive production of his pen evinced a gradual increase of mental power, which would have enabled him to achieve, had he lived, much more than he has done. He is said to have been carried off, after a few days' illness, by the typhus fever, which is at present so rife in Glasgow.

MEDICAL READING.

DURING the year 1836 there were published in France alone upwards of 300 volumes on the various branches of medical science. These 300 volumes, added to the numerous brochures, memoirs, and other smaller tracts which have appeared, raise the quantity to upwards of 115,000 pages, which, together with the journals and theses brought out at the same time, render the total above 180,000 pages. Now should there be found a reader intrepid enough to undertake the perusal of all this, his monthly task must be to wade through nearly 16,000 pages, and his daily performance must be on an average 500. So much for French medical literature merely; add English, American, German, &c.!

COLLEGE OF SURGEONS.

THE Hunterian Oration will be delivered by Sir Benjamin Brodie, Bart., on Tuesday, the 14th of February next, at five o'clock.

By order,
EDMUND BELFOUR, Sec.

NEW MEDICAL WORKS.

J. Paterson Clark's Treatise on the Teeth and Dentism. Square 12mo. 10s.

Swan's Illustrations of the Comparative Anatomy of the Nervous System. Part II. 4to. 7s.

Phillips's Translation of the New Pharmacopœia Londinensis. 8vo. 10s. 6d.

The Nervous System of the Human Body. By Sir C. Bell. Third edition, 8vo. 24s.

APOTHECARIES' HALL.

LIST OF GENTLEMEN WHO HAVE RECEIVED CERTIFICATES.

January 19, 1837.

William Vores, Northampton.
Ambrose Humphrys Ashley, Clifton, Bristol.
Henry Johnson, St. Helen's, Lancashire.
Richard Fell Gregg, Kirkby Lonsdale, Westmorland.
William Birtwhistle, Skipton-in-Craven.
William Goodwin Stone, Wentworth, Yorkshire.

BY WILLIAM CUMMIN, M.D.

LECTURE XIX.

LIVE AND STILL BIRTHS. *Statistics of the still born—Question of live birth: 1. In Civil cases—Legal distinctions—Law of Tenancy by the Courtesy—How modified by the Caesarian section—Success of this operation on the Continent, as compared with what has happened here—Notice of a celebrated English case. 2. In Criminal cases—Prohibitions. ABORTION OR MISCARRIAGE—Present state of the law on this subject in need of amendment—Objects of inquiry in cases of alleged Abortion—Medico-legal inspection of the Ovary or Fetus—Examination of the suspected female—Methods usually employed for procuring Abortion—Their precarious effects—Circumstances under which it may be sometimes justifiable to cause miscarriage.*

THERE remains one other point of view in which the births of children are to be medico-legally considered, and that, though last, far from being least in importance. Whether children are born alive or dead, often becomes a question fraught with the weightiest interest, both before our civil and criminal tribunals; and competent medical evidence can alone give it a satisfactory solution.

LIVE AND STILL BIRTHS

Statistics.—In the ordinary course of nature a certain proportion of children are still born. What that proportion is, it may be worth while to inquire, previously

fact in particular instances. In criminal cases, more especially, it may be important in favour of mothers accused of destroying their offspring, to know that a certain number of children are usually dead before delivery, subject to variation according to the operation of predisposing causes.

M. Quetelet, of Brussels, has made some interesting inquiries on this subject, and has found that there is a material difference in the mortality according as the births take place in cities or in the country, and according to the sexes of the infants. The number of still births occurring in towns is double that in the country; in the latter it is but one in every 31 births, while in the former it is one in about 16, and more boys perish than girls, in the proportion of three to two. Dr. Buck, of Hamburg, confirms those returns: on an average of eight years, he found the number of still-born to be to the number of births as one to 16; but the mortality of males was not quite so much—five to four expressed the ratio.

According to Dr. Denman, the proportion of still born in this country is, or was, not more than one in 16, or perhaps between that and one in 20. The returns of some of our lying-in institutions have of late given a much lower rate, such as one in 25, or even 28. In Ireland the mortality is greater. We find in Dr. Collins's work, which contains so many valuable statistical facts relating to midwifery practice, that of 16,654 children born in the Dublin Lying-in Hospital, 1121 were still-born, and 614 were males, that is, the still births were to the entire number of births in the proportion of above one in 15, and the males to the females nearly in the ratio of six to five. Some other facts worth noticing in this place are mentioned by Dr. Collins. Of the 1121 still-born children, 527 were putrid (one in 21), and 299 were expelled prematurely (one in

proportion born putrid — namely, about half the number of still-born; for where appearances of uterine putridity are present, the question of live or still-birth can scarcely be entertained, and our duty as medical jurists is accordingly much expedited and abridged.

The general conclusion from these data may be thus briefly expressed. Of the number of children born, from *five to seven per cent.* is the proportion of still births; and of these about *half* are putrid, and nearly a *fourth* premature.

1. In Civil Cases.

It will be convenient to divide the subject of live and still births, as it may happen to be inquired into, in civil cases or in criminal.

Legal distinctions. — The fact of live birth must be ascertained in all cases where property is transmitted through a new-born child. I have already mentioned that an infant in *ventre sa mère* may become possessed of property as a legatee, may have a surrender of a copyhold estate made to it, or may even take land by descent; but all this on the presumption of its subsequent live birth: hence the importance of being able to determine, in doubtful cases, whether it be live or still-born.

What is to be understood by *live* birth is variously interpreted by civilians and criminalists, and also by the jurists of different countries. Mr. Chitty says, "we would define it to be the arrival of the child at that stage after parturition, when its existence and capacity to continue life, separate and apart from the mother, has been distinctly established; and which consists not merely in breathing, but also in the exercise, at least for once, of all the functions essential to the continuance of life, and, amongst others, principally the circulation of the blood, the existence of which, at least *prima facie*, is essential to prove the infant's capacity to continue life."

But this limitation of live birth, however applicable to the case of injuries inflicted on the new-born child, implies a much higher standard of vitality than is requisite for securing the privileges of infants in a civil point of view. For the latter purpose it seems sufficient that the infant should exhibit *any* sign of life; nor is it necessary that it should be proved to possess a capacity for continuing to live. In France and other countries, the fact of *viability* must be made apparent, in order to secure the rights and privileges of the child. Here, even in criminal cases, the absence of *viability* is a circumstance which may or may not be taken into account, at the dis-

cretion of the court; but the mere fact of birth, with any appearance, however slight, of not being *still*, is all that is requisite to constitute the infant a transmitter of property.

Law of Tenancy by Courtesy. — There is a curious provision in the arrangements of our common law, for securing certain privileges to a husband who survives the marriage, and has had issue *live* born. It may be best explained by an example. A man marries a woman possessed of real or landed property; they have a child, still-born, and the wife afterwards dies. The property will go to the remotest relation of the wife — nay, in default of relations, it will become a forfeiture to the king rather than the husband shall have it. But let us suppose the child born alive, and to have lived even only an instant, the whole affair is altered; the husband then has a claim superior to that of any relative; he has a right to enjoy the property during his life; he becomes, in short, "tenant by the courtesy of the law of England."

In Scotland, in order to establish a *tenancy* of the kind, it must be proved that the child cried, that being considered requisite as sufficient evidence of vitality. In this country, too, it has been attempted to introduce the same necessary proof, but without success. Lord Coke objected to the position that the crying of the child should be held requisite; but his reason was an odd one — because the child might be deaf and dumb!

There can be no doubt but that the crying of the child after birth would be regarded by a jury as conclusive evidence of its being born alive; but much less proof has sometimes been held sufficient. In a very remarkable case, *Fish v. Palmer*, tried in 1806, the plaintiff had by his wife a child, supposed to be still born: the wife died, and there being no issue of the marriage, the estate went to the wife's brother-in-law. The husband, however, was afterwards induced to contest the fact of the child having been born dead. The accoucher, Dr. Lyon, had died before the trial, but it appeared in evidence, that he had declared the child to be living an hour before the delivery; and having directed a warm bath to be prepared, gave the child to the nurse to be immersed in it. It neither cried nor moved, nor did it shew any signs of life; but two women swore that, while in the hot water, there twice appeared a twitching and tremulous motion of the lips; and, upon informing Dr. Lyon of this, he desired them to blow into its throat; but it never exhibited any other signs of vitality. Drs. Babington and Haighton, who were examined on the trial, declared that the muscular motion of

he lips could not have happened if the fetal principle had been quite extinct, and that, therefore, the child was born alive. Dr. Denman, however, gave a contrary opinion, and declared that the child was not born alive; and he attempted to establish an important distinction between *terine* and extra-uterine life, and considered that the tremulous motion of the *ps* might arise from some remains of the *former*. The jury, however, did not agree with the latter witness, but found that the child was born alive.

Had Dr. Lyon acted in this case with more promptitude and energy, it is probable he would have saved some litigation; but as it is, the case affords a good illustration of the actual state of the law, and of the importance attaching to contemporaneous evidence. It shews the expediency of taking notes of what occurs at births, especially when children are born in a doubtful condition, or do not at all events live long. The circumstances attending the labour should be noted, and some memorandum preserved of the persons who may happen to be present. There have been instances of accoucheurs, after the lapse of many years, being called on to give evidence before the highest tribunal in the land, concerning births at which they may have assisted, and where the mothers were at the time in an humble rank of life.

It was in contemplation a few years since, among other projected alterations in the laws relating to real property, to render tenancy by the courtesy independent of issue—to enable the husband to become tenant without having had any children by his deceased wife. But no alteration of the kind has taken place; the law remains as it was, allowing the same attitude as ever for medical evidence and judicial discretion.

How modified by the Cæsarean section.—The occurrence of birth through the cæsarean operation may affect the tenancy, not only as the child may not be brought into the world alive, but as the mother may have died before the operation. The law

is clear on this point: "If the woman in *ex* travel dieth," says Coke Littleton, "and the child is ripped out of her body alive, yet shall the husband not be tenant by the courtesie; because the child was not born during the marriage, nor in the lifetime of the wife, but in the meantime the land descended; and in pleading he must allege that he had issue during the marriage."

But suppose the operation performed before the mother has expired, and that the child has lived, though it be but for an instant, tenancy is evidently created just the same as it would be were the

child born otherwise. It is easy to see, however, in what way litigation might ensue, should the mother expire under the operation, or should it be attempted to extract the child while the state of the mother as to life or death was unequivocal. The main question would be one of fact,—whether the child were extracted alive, the mother surviving the operation were it but for an instant?

There is obviously a strong inducement in the present state of the law, to have the operation performed on the yet living mother, where it appears not improbable that she may perish before the birth can be effected in the usual manner. And perhaps I may take this opportunity of throwing together some remarks on this formidable operation, which, indeed, claims the attention of the medical jurist scarcely in any other way than as now contemplated. It may, no doubt, be wantonly and mischievously had recourse to, and the mother's life be compromised in consequence; in which case certainly a medico-legal question would arise as to the propriety of having attempted, and the amount of violence effected by, the operation*; but the consideration of questions of this sort belongs to a subsequent part of the course. Here we may briefly inquire as to the chances of the operation creating a tenancy by the courtesy.

"I think," says Coleridge, in his *Table-Talk*, "there are only two things wanting to justify a surgeon in attempting the Cæsarean operation: first, that he should possess infallible knowledge of his art; and secondly, that he should be infallibly certain that he is infallible." The doubt here so emphatically intimated, of the unjustifiable nature of the operation, seems not to have been peculiar to Coleridge alone; it appears to be the national feeling. While other nations have been freely practising the cæsarean operation, and boasting of their success in its performance, it has been comparatively seldom attempted among us, and then apparently with results not such as to justify more frequent trials.

It is curious that there is no mention of the cæsarean operation in the writings of the ancient medical authors; probably because it was only performed on the dead. There was a law, however, as early as the time of Numa, that no pregnant woman should be buried until the fruit of her womb was extracted. Traditions, too, were prevalent, of various eminent persons who were thus "untimely ripped" from the uterus. Esculapius was cut out of his mother, Coronis, after she had been slain by Apollo; Scipio Africanus, the

* See MED. GAZ., vol. xl. p. 556.

conqueror of Hannibal, was born in this way; Julius Cæsar also, it is said, but erroneously; and the bold Macduff seems to have owed no small share of his success in combating his fierce antagonist, to the superstition attaching to his artificial birth.

Up to about the sixteenth century, it seems never to have been contemplated that the operation should be performed, save where the mother died undelivered. Rousset, a contemporary of Ambrose Paré's, first published a treatise, in which there was given an account of some cases of the operation being successfully performed, the women recovering. It was a sow-gelder, of Alespachen (as Baubin reports), who first set the example of it on the living woman—his own wife—and she afterwards bore several children.

Without entering into a detailed notice of subsequent authorities, I may come at once to comparatively recent times. Baudelocque has given an account of 73 operations, 31 of them successful; Sprengel mentions 106 cases, 61 of which were prosperous; and Simon, in the *Memoirs of the Academy of Surgery of Paris*, has noticed 64 successful cases, in 13 of which the operation was repeated; some of the patients having undergone it five or six, and one even seven times.

Notwithstanding this, the practitioners of Great Britain have not felt themselves much encouraged to practise the operation. They have rarely, if ever, resorted to it, except in cases of necessity, where, through pelvic distortion, or tumors, there was no chance of delivering the mother otherwise; nor have they thought themselves justified, like their continental neighbours, in substituting gastrotomy where craniotomy seemed adequate to effect the delivery. Hence, and not from any peculiarity in our climate or the constitution of our females, their little success. It appears, that out of about thirty instances in which the cæsarean section has been tried in this country, only one or two have terminated favourably, so far as the preservation of the mother has been concerned: and in the first and chief of these it has been doubted whether the operation was truly cæsarean—whether, in fact, *gastro-hysterotomy*, or section of both uterus and abdomen, was effected in it. The case to which I allude is related at length by the operator, Mr. Barlow, of Blackburn, in the *Medical Records and Researches*: a brief outline of it may not be uninteresting.

Jane Foster, a healthy woman, forty years of age, and who had had several children, fell from a loaded cart, the wheel of which passed over her pelvis as she lay

on her back. One of the *osæ ilii* was fractured, and much injury done to the *osæ pubis*. There was an elevation of the head of the thigh-bone on the left side, which, with her other sufferings, rendered the patient lame.

She afterwards became pregnant, and was taken in labour 22d November, 1788. Three or four days passed without prospect of delivery; the waters were discharged, and no part of the child could be ascertained to present within reach. A consultation was held, when Mr. Barlow, on examining per vaginam, found, to his great surprise, that he could barely pass his finger between the pubis and last lumbar vertebra, while the outlet was so contracted as scarcely to admit the introduction of three fingers. On a more strict examination, he felt a very evident depression of the *osæ pubis*, "with a protuberance in a direction somewhat more towards the hollow of the sacrum than in an exact line with the last lumbar vertebra." Mr. Barlow was induced to consider this protuberance as a deposit of bony matter, produced after a separation of the symphysis pubis caused by the accident; but in whatever way it originated, it projected to within half an inch of the sacrum. After four days' suffering, the pains of labour ceased: matters now became almost desperate, and the cæsarean operation was proposed. The woman herself consented to it without hesitation, and it was accordingly performed on the morning of the 27th. On laying open the "uterus," which was observed to be "very thin, scarcely exceeding that of the peritoneum," the child presented with its breech, and was extracted dead. The placenta and membranes were then removed without difficulty; nor did any hæmorrhage follow. The wound of the abdomen was united with a few sutures, and was healed by the sixth day. The womb contracted well; the lochia were as abundant as in ordinary cases, and, in short, no material accident having occurred, the woman was able to leave her bed by the 10th of December, and to resume her usual occupations on the 17th. She enjoyed good health afterwards, and survived for several years. When she died, her pelvis came into the possession of Mr. Barlow, and this drawing, the original of which was copied from nature, represents its malformed structure.

You observe the tuberosities of the ischia (*a, a,*) greatly approximated, and an almost complete obliteration of the arch of the pubis. The symphysis pubis projects outwards very remarkably, and the conjugate diameter is in consequence extremely contracted. In the pelvis stripped of its soft parts, this diameter was not more than an inch and an eighth, and through

smallest portion of its extent, the brim
measures above seven-eighths of an

FIG. 23.

case,—though suspected to be one in which the membranes merely were ruptured, and not the uterus—that organ previously ruptured—may serve as an example of the sort of contingency which British practitioners conceive as a venture on the operation; they employ it to those cases in which, from the extreme disproportion of the pelvic diameter to those of the foetus's head, there is no hope of extracting the infant by any other method. It deserves to be considered whether reluctance, or scruple, on the part of the physician, may not be carried too far, in view of that success which continental practitioners (Locher, Muller, and others, for example) have had, and whether hysterotomy might not safely be resorted to in every prospect of preserving both mother and child, in many cases where the usual method is to procure delivery by turning the head, or in other words, by merely destroying the child. Of the irascibility of divesting such an operation of its terrors, I need not say another word, as you must all be aware that, as a timely performance, so much of the bodily happiness of the patient and the recovery of the child depends.

I now proceed to consider the question of live or still birth, as it may be

2. In Criminal Cases.

Can any injury be done to a live-born child? It is murder, but in proof of this it must be shown that the child was alive.

I enter into an inquiry as to what is meant by being born alive, in reference to the charges, would lead us at once to the subject of infanticide. It will be profitable, however, before we come directly to that subject, to take a view of the injuries which are frequently

offered to the foetus, or embryo, before birth; for both topics may be considered as comprehended under one general head, with a common appellation—that of Prolicide, or the destruction of offspring; a term which I only wonder has not been more generally adopted.

Prolicide, then, embraces criminal abortion (or miscarriage, as the law terms it) and infanticide. I shall treat of each in order.

ABORTION, OR MISCARRIAGE.

The physiology as well as the morality of the ancients was so loose, that little or no compunction was experienced relative to the procuring of untimely birth. The legislators, in certain of the old communities, enjoined it as a duty on their citizens to check the population by the practice of infanticide, whenever their families attained a specified number; and they frequently did not wait for nature to complete the course of gestation, but practised foeticide, or, as it appeared to them, the mere removal of a visceral obstruction, as a thing not only convenient, but praiseworthy. No wonder it was so. Hippocrates, or rather the author of a tract attributed to him, held that the foetus was not endowed with life till thirty days after conception, if it were male, and not till forty-two, if female. Galen supposed that the foetus was not animated till forty days after conception; others were of opinion that it required for a male forty days, and for a female eighty days, before it possessed a vital principle. The Stoics, strangest of all, maintained that the foetus was destitute of life until the moment it expired; that is to say, that it was an unanimated though organic substance during the period of utero gestation. It is easy to see to what consequences such doctrines must have led wherever they were entertained. But even among the moderns, and where the advancement of knowledge should have taught people better, opinions much akin to those just noticed have been adopted and acted upon. Zacchia, the eminent Roman medical jurist, laid down sixty days as an equitable period within which abortion might be practised without any breach of morality or religion. This was probably a necessary allowance for the lax state of morals that still prevailed in the ecclesiastical communities, notwithstanding the purifying effects of the Reformation.

Legal distinctions.—But what shall we say of the English law, which, even at the present day, does not recognize the foetus in utero as endowed with life, till the time of quickening has been ascertained to have arrived? *Partus vivens in matris* is the designation by which it has been noticed in the older law books.

and some very material distinctions are made in our statute law, according to the period and circumstances of pregnancy.

In the earlier condition of our jurisprudence, abortion under any circumstances did not amount to murder; it constituted, however, in certain respects, a high misdemeanor. But Lord Ellenborough's Act (43 Geo. III., c. 59) introduced a change: if abortion was wilfully effected *before* quickening, it was accounted a felony, punishable with fine and imprisonment, or transportation for life: but abortion, *after* the period of quickening, when criminally procured, was punished as a capital crime with death.

The law which is now in force (9 Geo. IV., c. 31, s. 13) is almost identical, and is worded as follows:—"Be it enacted, That if any person with intent to procure the miscarriage of any woman *then being quick with child*, unlawfully and maliciously shall administer to her, or cause to be taken by her, any poison or noxious thing, or shall use any instrument or other means whatever with the like intent, every such offender, and every person counselling, aiding, or abetting, such offender, shall be guilty of felony, and being convicted thereof, shall suffer death as a felon. And if any person, with intent to procure the miscarriage of any woman *not being, or not being proved to be, then quick with child*, unlawfully and maliciously shall administer to her, or cause to be taken by her, any medicine or other thing, or shall use any instrument or other means whatever with the like intent, every such offender, and every person counselling, aiding, or abetting, such offender, shall be guilty of felony, and being convicted thereof, shall be liable, at the discretion of the court, to be transported beyond the seas for any term not exceeding fourteen years nor less than seven years, or to be imprisoned, with or without hard labour, in the common gaol or house of correction, for any term not exceeding three years; and if a male, to be once, twice, or thrice publicly or privately whipt (if the court shall so think fit) in addition to such punishment."

The absurd distinction here preserved in accordance with the old ideas about quickening, is disgraceful to our legislators; but I have it from good authority, that this is to be one of the very first points amended in the criminal code now in preparation: one punishment, and that not capital, is to be awarded for the crime, at whatever period of pregnancy it may be committed.

A case which may serve to illustrate the law in its actual state, occurred not very long since on the Norfolk Spring Circuit, before Mr. Baron Vaughan. John Coe was indicted for feloniously administering

savine to Henrietta Freeman, for the purpose of procuring miscarriage. Prosecutrix, who was but sixteen years of age, stated that the prisoner was the father of the child. When she told him she was pregnant, he said he would give her "some stuff to make her unwell, as she ought to be." She consented to take it, provided it did not hurt herself. The drug, according to prisoner's direction, was put into boiling water, and drunk off. In a short time she was unwell, and a miscarriage took place. It was proved that the prisoner had purchased a quantity of savine, and some of it was found in his box. A surgeon proved that miscarriage had taken place, and stated that no drug whatever could be administered for the purpose of procuring a miscarriage without endangering the life of the person by whom it was taken,—a fact which, he thought, ought to be generally known.

The prisoner was found guilty, and sentenced to seven years' transportation. He obviously owed his escape from capital punishment to its not being proved that the child was quick.

Objects of inquiry.—Whenever a question concerning a criminal abortion is raised, there are in general three points on which justice will require to be satisfied. 1. Whether there has really been an abortion; in other words, whether a *corpus delicti* can be made out. 2. Whether it has taken place naturally or by criminal interference. And 3. Whether it may not have been justifiable, owing to some peculiar circumstances in the physical condition of the female. On each of these heads I shall make a few remarks.

1. *The fact of abortion.*—The main proof that abortion has occurred, is the presence of the fœtus or the ovum. Without this the investigation is defective, and halts at the very outset.

The embryo may happen to be expelled at a very early period, when the ovum, coming away entire, presents a shaggy appearance on immersing it in water. At a later period the membranes may burst, and the fœtus alone be found in the discharges. Sometimes the entire ovum is enveloped in a clot of blood, and may easily escape detection, unless much care be taken in searching for it. It may even be necessary to steep the suspected clot for a day or two in water. In general we should examine an early ovum with the greatest caution. By gentle agitation and the use of the syringe, the coagulated blood may be removed; after which, by delicate dissection under water, and using fine, but not sharp, instruments, its real nature may be made out.

A careful search of this kind, not only to ascertain whether there be an embryo

present, but whether it be normal or the contrary—blighted, is absolutely necessary in such cases as come under the cognizance of the medical jurist. Here, for example, is an ovum which, by being prepared in this way, tells its own story.

FIG. 24.

You perceive, from the relative disproportion of the embryo (c) and its envelopes (b, a), that the general structure is abnormal. It is, in fact, an ovum which was expelled about the eighth or tenth week of pregnancy; and the embryo (c) perished about the fifth or sixth week, probably from the deposition of too much gelatine (d) in the funis, the vessels of which were thus compressed. Appearances of this description should go far towards annulling a charge of criminal abortion, for they imply strongly that the event occurred in the ordinary course of nature.

The rules already laid down in a former lecture* will suffice to enable you to form an opinion of the age of the foetus, and to state in every case, if not at what time during the pregnancy the miscarriage occurred, at least at what period the foetus perished. I shall therefore not detain you longer on these points.

The next step is to trace the ovum or foetus to the source from which it came. Some female is suspected. We must examine her,—when, according to the period that shall have elapsed from the occurrence of the abortion, the appearances will be varied. If there be symptoms of recent hæmorrhage,—if a lochial discharge be present,—if the vagina, or uteri, labia externa, and the mammae, be in those conditions which I described in a former lecture on the signs of recent delivery,—the proofs are strong. It may happen that the

supposed mother has died, in which case the examination of her body may throw additional light on the circumstances of the case: the uterus will probably be found enlarged, and thickened, and vascular, and a placental mark may be found, and perhaps a corpus luteum; but above all, in the examination of the mother, we must be able to satisfy ourselves that the period indicated to have past since abortion correspond with that which has appeared to have elapsed since the foetus was expelled; and the foetus must accordingly be scrutinized with reference to these points, as well as to any marks of violence discoverable upon it.

2. *Mode in which effected.*—When we have thus been satisfied that the charge of abortion is not groundless, our next inquiry, and one that must be entered upon without loss of time, is—to what the occurrence of abortion has been owing? We must recollect that such an event may have been wholly accidental and involuntary, and yet that nothing may have been more natural than its concealment in certain moral circumstances. With this saving clause, however, it will probably be in most cases our painful duty to detect much vicious and wicked manœuvring on the part of females to bring on the expulsion of an ovum. I happen to be acquainted with one instance of a lady who, at a certain period of her pregnancy—about the tenth or twelfth week—regularly took a short sea voyage, which never failed to enable her to abort. And it is a very common practice for women to have recourse to drastic cathartic medicines, to large bleedings, to cantharides, savine, and other drugs, for the accomplishment of their depraved and dangerous purpose. Nay, we shall sometimes detect the marks of blows on the abdomen and loins, and the appearance of mechanical injury inflicted on the foetus itself. To what extent, however, personal violence may be employed without procuring abortion, is well exemplified by a case that occurred not long since in Dr. Wagner's practice at Berlin. "Among the remarkable cases which came before us," says the Professor, in his half-yearly report, "was one of attempted abortion. A young woman, seven months with child, had employed savine and other drugs, with a view to produce miscarriage. As these had not the desired effect, a strong leather strap (the thong of a skate) was tightly bound round her body. This, too, availing nothing, her paramour (according to his own confession) knelt upon her, and compressed the abdomen with all his strength: yet neither did this effect the desired object. The man now trampled

back; and as this also failed, he took a sharp-pointed pair of scissors and proceeded to perforate the uterus through the vagina. Much pain and hæmorrhage ensued, but did not last long. The woman's health did not suffer in the least, and pretty much about the regular time a living child was brought into the world, without any marks of external injury upon it."

Not rarely does it happen that the females who are so abandoned as to practise these methods of procuring miscarriage, pay the forfeit of their lives for their wickedness. All the means which I just now enumerated are attended with extreme danger to the mother, whom they often destroy, not only without concealing the nature of her guilt or letting it die with her, but perhaps causing a dreadful *exposé* of her guilty object first, and then producing an agonizing death, with all the tortures of remorse. Foderé cites a remarkable case:—A woman, finding herself pregnant, and no longer able to conceal it, procured half an ounce of powdered cantharides, which she mixed with an ounce of sulphate of magnesia. She took this horrible dose in order to procure abortion. In a short time after she was seized with violent colic, and brought forth a living child in the most excruciating pains. During the succeeding night she died.

3. *Question of necessity.*—I have only a few words to say on the third question—namely, whether it be ever justifiable to cause miscarriage, or, in other words, whether a midwife or an accoucheur may bring on artificial labour? According to the strict interpretation of the law, they may not, even in cases of hæmorrhage or convulsions: but no doubt, if such an occurrence were pleaded on an indictment for alleged procural of abortion, the intentions of the accused and the circumstances of the case would have due weight with the jury; and the probability is that no grand jury would find true bills.

But this is supposing a case of manifest danger to the mother. What if the pregnant woman be not in immediate danger, but from the configuration of her pelvis, or some constitutional peculiarity, it be thought advisable by her medical attendant to bring on premature labour? Is it justifiable in such a case? Opinions are divided upon it; and the French authorities have argued the point at much length. Foderé strongly advocates such a discretionary power in the accoucheur: while Capuron as strongly opposes it; and his reasons are these—1. That it is always impossible to be certain that there is such a disproportion between the diameters of the pelvis and the bulk of the child as to warrant artificial delivery; and we know not

what extraordinary efforts nature may make for the unaided relief of the mother. 2. That these premature labours frequently kill the child, and may the mother. And 3. That a supposed danger is not to be combatted with a real one. He concludes by deliberately stating, that it is better by far to have recourse to the *cæsarean section*, which, he says, *saves one in three*,—or even to symphysiotomy,—than to an artificial or forced delivery.

It seems to me that Capuron carries his notions on this point to a very unreasonable extent; and I believe I am borne out in saying so, by referring to what seems to be the practice of some of the best authorities amongst us on these matters. Dr. Hamilton, of Edinburgh, for example, is in the habit of bringing on premature labour in cases where he has reason to suppose that the child will not live, or may be born still, if the mother be allowed to go to the full term of gestation*. And others might be quoted to the same effect.

LECTURES

ON

MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, Esq., F.L.S.

LECTURE LVI.

WE shall now examine—

UMBELLIFERÆ, OR APICÆÆ,

one of the largest, and, in reference to structure, one of the most natural families of the vegetable kingdom: moreover, it is a most interesting one for the physician, inasmuch as it contains a variety of dietetical, medicinal, and poisonous substances, in common use.

The roots are annual or perennial; the stems herbaceous and fistular; the leaves usually divided (though sometimes simple), and sheathing at their base; the flowers small, and arranged in umbels, from which circumstance the name of the family has been derived. At the base of the general umbels there is usually an involucre (*involucrum*); and in the same position in the partial umbels an *involu-cellum*. The calyx is superior, commonly five-toothed; the corolla is composed of

stals, usually indexed at the point. are five stamina, and usually two s; so that umbelliferous plants be- o class *Pentandria*, order *Digynia*, of innean arrangement.

fruit, called by botanists *cremocarp*- or *diaknium*, is usually termed by inneanists, though very improperly.

Thus, in medicine we find the fruit iander, dill, caraway, cumin, anise, fennel, hemlock, &c. generally termed but in the new edition of the London nomenclature this has been corrected. fruit consists of two parts (termed 1, *carpella*, or *mericarps*), adherent to a on axis by their face (the *commisure*.) carpel is traversed by ridges, of which re primary (*costæ seu juga primaria*), our are intermediate or secondary (*secundaria*). the spaces between the are called *channels* or *interstices* (*valle-*

the substance of the pericarp there ually linear receptacles of a brown ; filled with volatile oil; they are *vittæ*, or, by DeCandolle, *reservoirs* *en* ; they are considered to be dilata- of the intercellular spaces. Com- ing from above, they extend down- in different species, one-third, half, ee-fourths, the length of the fruit. are often visible both on the com- re and in the channels. By a trans- section of the fruit, they appear as points. The fruit of the parsnip *sativa*, fig. 151) is well adapted berving the *vittæ*, especially if it viously immersed in warm water.

10. 151.—Fruit of *Pastinaca sativa*.

A, Dorsal surface.

B, Horizontal section of the fruit.

c c, *juga primaria*; 1, 2, 3, 4, 5, 6, *vittæ*.

are not invariably present; the of conium, and of some other genera, without them: the carpella of such are said to be *ecittatæ*. Of course re without aroma.

ruit with only four dorsal vittæ is said *pauci vittatum*, as in *Pastinaca*; when than this number, *multi vittatum*.

aromatic properties of the fruit of *Bituminaria* of caribbees, anise dill

caraway, fennel, carrot, &c.) depend on a volatile oil secreted into, and contained in these vittæ.

The seeds of Umbelliferæ are albumi- nous: the albumen may be flat (*Umbelli- feræ orthosperme*), or it may be rolled in- wards at the edges (*U. campylosperme*), or it may be curved inwards from the base to the apex (*U. calosperme*.) The embryo is minute.

Anethum graveolens, or *Dill* (*Pastinaca Anethum* of Sprengel).

This plant was employed by Hippocrates under the name of *anodon*; it is mentioned by Dioscorides and Pliny. It is said by Campbell to be alluded to in the New Testament, though our translators have, by mistake, rendered the original word anise. It was introduced into this country in 1570.

Dill is a native of the south of Europe, as of Spain and Italy. It greatly resem- bles our common fennel, though its odour is less agreeable. The mature carpella (the *semina* or *fructus anethi* of the shops) are oval, flat, dorsally compressed, about a line and a half long, and from a half to one line broad; they are of a brown colour, and are surrounded by a lighter-coloured membranous margin (*ala*.) Each carpellum has five primary ridges, but no secondary ones. In each channel is one vittæ, and on the commissure are two vittæ. These vittæ contain the aromatic oil. The odour of the fruit is strongly aromatic; the taste warm and pungent.

By distillation a pale yellow volatile oil (the *oleum anethi*) is obtained, the quantity of which varies with the maturity of the fruit. This oil has a specific gravity of 0.881, a penetrating odour analogous to that of the fruit, and a hot sweetish taste. It is readily soluble in alcohol and æther, and dissolves, according to Tietzmann, in 1440 parts of water.

The effects of dill are carminative and stimulant. Taken with the food it may be regarded as condimentary; that is, it assists the digestive process. For this purpose it is used by the Cossacks, and some other inhabitants of the Russian empire. It excites a sensation of warmth in the stomach, expels wind, and relieves some painful affections of the alimentary canal, of a spasmodic nature: hence it is used by nurses in the colic of children. It has also been employed to relieve hic- cough. It has been supposed to promote the secretion of milk. It is usually given in the form of dill water (*aqua anethi*.) For adults the *oleum anethi* may be employed in the dose of a few drops on a lump of su- gar, or dissolved in spirit.

Laudon says the leaves of dill "are

table pickles, particularly cucumbers; and also occasionally in soups and sauces."

Pimpinella Anisum, or *Anise* (*Sison Anisum* of Sprengel).

This plant was used by Hippocrates, who calls it *ανησον*; it is also mentioned by Pliny and Dioscorides. It was introduced into this country in 1551. In our translation of the New Testament the word *anise* occurs; it should have been *dill*.

Anise is a native of Egypt and the Levant. It is largely cultivated for its fruit in Malta, Spain, and at various places in Germany, as at Erfurt and Mühlhausen, in Thuringia, at Magdeburg, &c. This fruit is imported into this country from Alicant and Germany.

The fruit (called in the shops *semina* or *fructus anisi*) is slightly compressed at the sides. The separated carpella are ovate, of a greyish green colour, with five paler, thin, filiform, primary ridges (there are no secondary ones), and covered with downy hairs. In each channel are three vittæ. The odour is aromatic, and similar to that of the fruit of *Illicium anisatum*, or *star anise*, a plant belonging to the family Winteraceæ. The taste is sweetish and aromatic.

A very elaborate analysis of the fruit has been made by Brandes and Reimann, in 1826. The following are their results:

Ætherial oil.....	3.00
Stearin combined with chlorophylle.....	0.12
Resin	0.17
Fatty oil, soluble in alcohol ..	3.37
Semi-resin.....	0.40
Phyteumacolla.....	7.85
Incrystallizable sugar.....	0.65
Gum	6.50
Extractive.....	0.50
Substance analogous to ulmin (<i>Anis-ulmin</i>)	8.60
Gummin	2.90
Lignin	32.85
Salts (acetate, malate, phosphate, and sulphate, of lime and potash)	8.17
Inorganic salts, with silicic acid and oxide of iron	3.55
Water	23.00

101 63

Oleum Anisi.—The oil of anise of the shops is imported into this country from Germany and the East Indies. It is procured by distillation from the fruit, in whose pericarp it resides. When carefully prepared it is transparent and nearly colourless, having a slightly yellow tinge. It has the odour and taste of the fruit from which it is obtained. Its specific gravity increases with its age: thus Martius says when the oil is fresh distilled, the specific

gravity is only 0.979; but after keeping it for a year and a half, the specific gravity increased to 0.9853. It congeals at 50° F.; and does not liquify again under 62°. It is soluble in all proportions in alcohol; but spirit whose specific gravity is 0.84, dissolves only 0.42 of its weight. By exposure to the air it forms resin, and becomes less disposed to congeal. It is composed of two volatile oils—one solid at ordinary temperatures (*stearoptene*); the other liquid (*eleoptene*), in the following proportions:—

Eleoptene.....	75
Stearoptene	25
<hr/>	
100	

The *oleum badiani*, or the oil of *star anise* (*Illicium anisatum*), has the odour and taste of the oil of anise; but it preserves its fluidity at 35.6 F. It is said to be sometimes substituted for the *oleum anisi*.

Spermaceti, which is sometimes added to oil of anise, to promote its solidification, may be distinguished by its insolubility in cold alcohol. Camphor, which is said to be added for the same purpose, may be recognised by its odour.

Effects.—The effects of anise are similar to those of dill, before mentioned; that is, they are condimentary, stimulant, and carminative. The odour of the oil is said to be recognized in the milk: moreover, the urine, we are told, acquires an unpleasant smell when anise has been taken: hence it would appear that the oil of anise becomes absorbed. It has been supposed to promote the secretion of milk, urine, bronchial mucus, and of the menses, though without sufficient evidence. Vogel says that he accidentally discovered pigeons are readily killed by a few drops of the *oleum anisi*.

Uses.—Anise is used to flavour liqueurs, sweetmeats, confectionery of various kinds, ragouts, &c.

In medicine it is employed to relieve flatulence and colicky pains, especially of children. Nurses sometimes take it to promote the secretion of milk. It has also been employed in pulmonary affections.

The *aqua anisi* is the preparation of anise commonly employed. In the Pharmacopœia there is a formula for a *spiritus anisi*, the dose of which is one or two drachms. A spirit of anise, sweetened with sugar, is sold by the liqueur dealers: a somewhat similar compound is prepared in France, under the name of *crème d'anise*. In the Dublin Pharmacopœia there is a compound spirit of anise, containing angelica: it is nearly the composition of the Irish *usquebaugh*, which is coloured yellow by saffron, or green by sap green.

Carum Carui, or the Caraway.

Caraway (fig. 152, b) is not mentioned in the writings attributed to Hippocrates. Pliny and Dioscorides, however, speak of it: the former calls it *Careum*, from Caria, its native country, the latter *aspos*.

FIG. 152.—(a.) *Coriandrum sativum*.
(b.) *Carum Carui*.

It is a native of this country, and is largely cultivated in Essex, for medicinal and other purposes—as for distillation with spirituous liquors, and for confectionary. The ripe carpella (the *amina*, or *fructus carui*, of the shops) are partly supplied from Germany, the remainder being the produce of this country. They are from $1\frac{1}{2}$ to 2 lines long, usually separated, slightly curved inwards, of a brownish colour, with five lighter coloured primary ridges; there are no secondary ones. In each channel is one vitta, and on the commissure are two. The smell is aromatic and peculiar, the taste warm and spicy.

By distillation, a volatile oil (*oleum carui*) is obtained, of a pale yellow colour.

The action of caraway is analogous to that of dill and anise, already mentioned, and it is employed in similar cases—namely, in flatulent colic of children. It is used in domestic economy, confectionary, &c. on account of its flavour; but it is also useful as a condiment.

The official preparations of this substance are the *aqua*, the *oleum*, and the *spiritus carui*. The spirit, sweetened with sugar, is taken in Germany as a dram. Caraway in substance, or in the form of oil, enters as an adjuvant, or corrective, into various official preparations; as the confection of opium, of rue, and of scammony; the compound tincture of cardamom and of senna; the compound pills of aloes and of rhubarb; and the compound spirit of juniper.

Coriandrum sativum, or Coriander (fig. 152, a.)

This is the *sempervivum* of Hippocrates. It is mentioned also by Pliny and Dioscorides.

It is a native of the south of Europe, and is cultivated in Essex. The ripe fruit (*amina*, or *fructus coriandri*), as met with in the shops, is globular, about the size of white pepper, of a greyish-yellow colour, and is finely ribbed. It consists of two hemispherical carpella, adherent by their concave surfaces. Each carpallum has five primary ridges, which are depressed and wavy; and four secondary ridges, more prominent and carinate. The channels are without vitta, but the commissure has two. The odour of coriander is peculiar and aromatic.

By distillation, a volatile oil is obtained; on this the odour, taste, and medicinal properties of the fruit depend. It resides in the vitta of the pericarp.

The effects and uses of coriander are similar to those of the preceding fruits. Cullen considered it as more powerfully correcting the odour and taste of senna than any other aromatic; and hence at one time it was a constituent of the compound infusion of senna, though now ginger is substituted for it.

There are no distinct preparations of coriander; but it enters into one official compound—namely, confection of senna.

Besides its medical uses, coriander is employed by confectioners and distillers.

Cuminum Cyminum, or Cumin.

This plant is mentioned in both the Old and New Testament, and by Hippocrates, who calls it *sempervivum aspidocoryon*. It is also noticed by Pliny and Dioscorides.

It is a native of Egypt, where, as well as at Sicily and Malta, it is cultivated, and from which place all the cumin of commerce is brought. The ripe carpella (*amina*, or *fructus cumini*) are larger than anise, and of a light brown colour. Each carpallum has five primary ridges, which are filiform, and furnished with very fine prickles. The four secondary ridges are prominent and prickly. Under each of these is one vitta.

Like the preceding umbelliferous fruit, cumin yields a volatile oil (*oleum cumini*) by distillation.

Its medicinal properties and uses are similar to the substances of this family already described. As there is now no preparation of cumin in the new Pharmacopœia (the *emplastrum cumini* of the preceding editions being omitted), I am surprised that the College has still retained this substance in the list of the *materialia medica*. It is principally employed in

Daucus Carota; the Carrot.

The carrot plant is too well known to require much description. Hippocrates speaks of the *dauros*, which some consider to be the *Athamanta cretensis*, whose fruit is termed *semina dauci cretici*.

The carrot is a native of this country. For medicinal uses we employ the well-known root and the fruit.

(a.) *Radix dauci*.—Carrot-root consists principally of lignin, sugar, starch, a volatile and fixed oil, a colouring matter, and a super-malate of lime. Wackenroder obtained half a drachm of colourless ætherial oil out of thirty-four pounds of the fresh root: it had a peculiar penetrating odour, and an unpleasant taste. The expressed juice, evaporated to dryness, is composed, according to the same authority, of

Uncrystallizable sugar, with some starch and malic acid	93.71
Albumen	1.33
Fixed oil, mixed with some ætherial oil	1.00
Red crystallizable resinous substance (<i>carotin</i>)	0.34
Ashes composed of alumina, lime, and iron	0.60
	100.00

By the action of alkalis on the ligneous tissue of the carrot, Braconnot procured *pectic acid*.

The dietetical uses of this root are well known. In medicine we sometimes employ it in the preparation of a poultice, the *cataplasma dauci* of the Dublin Pharmacopœia. It is prepared by boiling the root in water until it become soft enough to form a cataplasm. In this state it is used to correct the foetid discharge, allay

the pain, and change the action of ill-conditioned, phagedenic, sloughing, and cancerous ulcers. If prepared by merely scraping the root, it is much more stimulant, and is sometimes applied to chapped nipples.

(b.) *Fructus dauci*: *semina dauci* of the shops. The fruit is from one line to a line and a half long, brown, oval, convex on one side, flat on the other. The five primary ridges are filiform and bristly: three of them occupy the convex back, the remaining two are on the plane of the commissure of the carpellum. The four secondary ridges are much larger and more prominent than the primary ridges; they are furnished with prickles. Under each of the secondary ridges is a vitta, and on the plane of the commissure are two, making in all six. The odour is peculiar and aromatic, the taste bitter and warm. By distillation, a volatile oil is procured.

Carrot fruit exerts a similar influence over the system to the before-mentioned umbelliferous fruits; but it is supposed to act more particularly on the urinary organs, and is in consequence recommended in some nephritic complaints.

Feniculum vulgare: common fennel.

It grows wild in the south of Europe. The fruit (*semina feniculi vulgaris* of the shops) is scarcely two lines long, oval, and of a dark or blackish aspect. Each carpellum has five obtusely-keeled pale yellowish grey primary ridges. In each channel is one vitta, (on which the brown colour of the channel depends), and on the plane of the commissure are two. The oil, obtained from the fruit by distillation, is called in the shops the *oil of wild fennel*. The fruit of this species is not used in medicine.

FIG. 133.—*Feniculum vulgare*.

Feniculum dulce.

Sweet fennel is by some regarded as a variety of the preceding species: but DeCandolle considers it a distinct species. Its fruit is much longer, some of the specimens being nearly five lines in length, less compressed, somewhat curved, and paler, than the kind before-mentioned, with a greenish tinge. The oil obtained from it is called the *oil of sweet fennel*.

The effects and uses of sweet fennel are similar to those of the before mentioned umbelliferæ. The only official preparation is the *aqua fœniculi*, but the fruit enters into the composition of some of the preparations—as the confection of black pepper and spiritus juniperi compositus.

Ferula Asafetida.

History.—It is uncertain at what period *asafetida* was either first known or described. The difficulty in determining its history arises from the uncertainty as to the ancient synonymes of this substance. Hippocrates, Theophrastus, and Dioscorides, speak of a plant which they term *silphium*, and which is supposed by some to be the plant yielding the *asafetida*. In the scholia of Aristophanes the discovery of this plant is attributed to one Aristæus, about 617 years before Christ,—a date which, as Sprengel observes, agrees very well with the statement of Theophrastus and Pliny, who tell us *laserpitum*, or *silphium*, was known seven years before the foundation of Cyrene; that is, six hundred years before the birth of Christ.

From *silphium* was obtained, by scarifying the root or principal stem, a juice which was termed *laser*, and, when obtained from plants growing in Cyrene, the *succus Cyrenæicus*. In the time of Pliny, however, the Cyrenæic juice was no longer procurable. "For many years," says this writer, "this plant has not been found in Cyrenaica, because the publicans [or farmers] who rent the pastures, finding it more profitable, destroy it as food for cattle. One stalk only, found in our days, was sent to the emperor Nero. We may know when cattle meet with young shoots of it, by the sleeping of the sheep when they have eaten it, and the sneezing of the goats. For a long time past the only laser brought to us is that which is produced abundantly in Persia, Media, and Armenia, but it is far inferior to the Cyrenæic."

Several reasons have led to the belief that the *laser* of the ancients is identical with our *asafetida*. Geoffroy has summed up these so briefly, that I cannot do better than quote him. "Forasmuch as it is now almost universally agreed, that

Persia is the native soil of *laser* and of *asafetida*; that the use of this at present among the Indians, is the same with the use of *laser* among the ancients; that their esteem for it is the same; that *asafetida* is at this time prepared in Persia entirely in the same manner as the juice of *silphium* was formerly; and lastly, that the juice of the Cyrenæic *silphium* only differs from the Persian in mildness of smell. We may certainly conclude that the *silphium*, *laser*, and *succus Cyrenæicus* of the ancients, and the *asafetida* of our shops, are not juices of distinct kinds, but the same, differing very little from each other."

Lieut. Burnes, in his "*Travels in Affghanistan*," says—"that at the pass of 'Dundan Shikun,' or the 'Tooth-breaker,' we found the *asafetida* plant in exuberance, and which our fellow-travellers ate with great relish. The plant, I believe, is the *silphium* of Alexander's historians, for the sheep cropped it most greedily, and the people consider it nutritious."

My friend, Dr. Royle, thinks that from the locality and uses of *Prangos pabularia*, this plant corresponds more nearly with the *silphium* of some of the ancients.

Botanical history.—The plant yielding *asafetida* was first accurately determined by Kämpfer in 1687, and the description of it published in 1712. He terms it *Ferula Asafetida*. Dr. Royle thinks it probable that more than one species of *Ferula* yields this gum resin in the different parts of Persia, Caubrel, and Bokhara.

Ferula Asafetida is a native of Persia, growing in abundance on the mountains of Chorasan and Iasr. Lieut. Burnes found it at an elevation of 7000 feet on the Hindoo Kooch. The root is perennial, large, black externally, white internally, and filled with a milky alliaceous juice: near the top it is beset with many strong rigid fibres. It continues many years in the earth, increasing in bulk. The stem is round, simple, and attains a height usually of 6 or 8 feet (8 or 10, according to Burnes). The radical leaves are pinnate, with sinuated pinnulæ: in regard to their shape, Kämpfer compares them to the leaves of *Pæonia officinalis*, but in colour and other respects they resemble *Ligusticum Levisticum*, or *Lovage*. The umbel is many rayed, and without involucre.

Preparation.—*Asafetida* is prepared by making transverse incisions into the upper part of the root; the footstalks of the leaves and the fibres at the root, having having been removed some weeks previously. The milky juice which exudes, is, after some days, scraped off, placed in cups, and hardened in the sun.

Physical properties.—I am acquainted with two varieties only of *asafœtida*, but Martius describes three.

(a.) *Asafœtida in the tear: asafœtida in granis seu in lachrymis.*—This kind occurs in distinct, roundish, flattened or oval tears, and also in irregular pieces, varying from the size of a pea to that of a walnut, of a yellow or brownish yellow colour externally, but white internally. This kind is rare.

(b.) *Asafœtida in the mass: lump asafœtida: asafœtida in massis.*—This variety is that usually met with in the shops. It occurs in variable sized masses, of irregular forms, and having a reddish or brownish yellow colour. Frequently these masses are observed to be made up of the before-mentioned tears, agglutinated by a reddish brown substance: these form that kind of *asafœtida* sometimes denominated *amygdaloid (asafœtida amygdaloides)*.

Martius describes a third kind of *asafœtida*, under the name of *asafœtida petraea*. He says it occurs in irregular more or less angular pieces, and externally resembles dolomite.

Both the above varieties agree in certain properties. Thus their taste is acrid and bitter, and their odour strong, alliaceous and peculiar; to most persons being remarkably disagreeable, whence the Germans have denominated *asafœtida*, *Teufels-dreck*, or *stercus Diaboli*; in plain English, *Devil's dung*. However, this dislike to the odour of *asafœtida* is not universal: some of the Asiatics being exceedingly fond of this drug, taking it with their food as a condiment, or using it to flavour their sauces, or even eating it alone. Hence among some of the older writers we find it denominated *Cibes deorum*,—*food of the Gods*. Captain M. Kinnier tells us that in Persia the leaves of the plant are eaten like common greens, as is the root when roasted: and Lieut. Burnes, in his *Travels in Bokhara*, speaking of *asafœtida*, says, "in the fresh state it has the same abominable smell; yet our fellow travellers greedily devoured it." But the fondness for this substance is not confined to the Asiatics: for I am assured by an experienced gastronome, that the finest relish which a beef steak can possess, may be communicated by rubbing the gridiron on which the steak is to be cooked, with *asafœtida*.

The fracture of *asafœtida* is conchoidal, white, or milk-white, with a waxy lustre. By exposure to light and air, the recently fractured surface acquires in a few hours a violet red, or peach-blossom red colour; but after some days or weeks, this colour diminishes in intensity, and gradually passes into a reddish or brownish yellow.

Asafœtida is fusible and inflammable;

burning in the air with a white flame, and the evolution of much smoke.

Chemical composition.—The most important constituents of *asafœtida* are volatile oil, resin, and gum. The active principles are the oil and the resin. It has been analysed by Trommsdorf, Meissner, Pelletier, and Brandes: the most elaborate analysis is that made by the latter chemist. From the large quantity of saline matters which he found, he called *asafœtida* a *saline gum-resin*. Pelletier's analysis, which, on account of its conciseness, I shall quote, agrees for the most part with Brandes', but it is not so detailed, and the saline constituents are not so fully made out.

Resin	65.00
Gum	19.44
Bassorine	11.66
Volatile oil	3.60
Supermalate of lime, and loss ..	0.30

100.00

1. *Volatile oil of asafœtida.*—This is obtained by distilling *asafœtida* with either water or alcohol. It is on this principle that the odour of this gum-resin depends. It is lighter than water, and is at first colourless, but by exposure to the air acquires a yellow tinge. It dissolves in all proportions in alcohol and æther, but requires more than 200 times its weight of water to dissolve it. Its taste is at first mild, then bitter and acrid; its odour is very strong. It evaporates very quickly, and soon fills a large room with its odour. Sulphur, and probably phosphorus, are among its elementary constituents. The presence of sulphur in *asafœtida* is shown in various ways: thus if chloride of barium be added to water distilled from *asafœtida*, and likewise a little chlorine, the sulphur becomes gradually acidified, and after some time a precipitate of sulphate of baryta is formed. Moreover, if pills made of *asafœtida* be rolled in silver leaf, the latter, after a few days, is blackened by the formation of a sulphuret of silver.

2. *Resin of asafœtida.*—According to Brandes, the resin of *asafœtida* is of two kinds: one insoluble, the other soluble in æther. The proportion of the first to the second is as 1.6 is to 47.25. When the tincture of *asafœtida* is added to water, a milky mixture is formed by the deposition of the resin. It is to this resin that *asafœtida* owes its property of reddening when exposed to air and light. *Asafœtida* resin is distinguished from other resins by the blue-coloured layer produced when acid solutions of it are neutralised by alkalies.

3. *Gum and bassorine.*—These constituents agree in being insoluble in alcohol. Bas-

sorine differs from gum, in being insoluble in water.

4. *Saline and other constituents.*—According to Brandes, asafœtida contains a considerable quantity of saline matter—namely, the malates, acetates, sulphates, and phosphates of potash and lime, and carbonate of lime. Oxyde of iron, alumina, phosphorus, and sand, (silicic acid) are also mentioned by him among the constituents of asafœtida.

Solubility of asafœtida.—From the preceding account of the constituents of asafœtida, it will be evident that neither water nor alcohol can perfectly dissolve this substance: the first will not act on resin, the second cannot dissolve the gum. Proof spirit is one of the best solvents. Alcohol will extract all the active matter of asafœtida.

Physiological effects.—Asafœtida is usually placed by pharmacological writers among those remedies which they denominate antispasmodics or stimulants. Its local effects are moderate: it is devoid of those acrid and irritating properties possessed by some resins and gum-resins, as gamboge, euphorbium, scammony, &c. In the mouth, as already mentioned, it causes a sensation of heat, and the same effect, accompanied by eructations, is experienced in the stomach, when asafœtida is swallowed. In Professor Jörg and his pupils (males and females), who endeavoured to elucidate the effects of this medicine, by experiments made on themselves, doses of asafœtida not exceeding a scruple, caused uneasiness and pain of the stomach, increased secretion of the gastrointestinal membrane, and alvine evacuations. The pulse was increased in frequency, the animal heat augmented, the respiration quickened, and the excretions from the bronchial membrane and skin promoted. A very constant effect was headache and giddiness. The urino-genital apparatus appeared to be specifically affected, for we are told in the males there was an increase of the venereal feelings, with irritation about the glans penis; while in the females the catamenial discharge appeared before its usual period, and uterine pain was experienced.

These stimulant effects of asafœtida were observed in a greater or less degree in all the nine persons experimented on; and it should be borne in mind, that the dose did not, in any one case, exceed a scruple. It is impossible to reconcile these results and the observation of practitioners generally, with the statement of MM. Trousseau and Pidoux, who tell us that they have taken half an ounce of good asafœtida at one dose, with no other effect than that of altering the odour

of their secretions, by which they were kept for two days in an infected atmosphere, possessing a more horrible degree of fœtidity than even asafœtida itself!

Modus operandi.—Asafœtida, or its odorous principle, becomes absorbed by the veins, though slowly. Flandrin gave half a pound of this gum-resin to a horse; the animal was fed as usual, and killed sixteen hours afterwards. The odour of asafœtida was distinguished in the veins of the stomach, of the small intestine, and the cæcum: it was not noticed in the arterial blood, nor in the lymph. Tiedemann and Gmelin were not successful in their search for it: they gave two drachms of asafœtida to a dog, and at the end of three hours, were unable to recognise the odour of it either in the chyle of the thoracic duct, or in the blood of the splenic and portal veins: but they detected it in the stomach and small intestines.

In farther proof of the opinion that asafœtida becomes absorbed, may be mentioned the detection of the odour of this substance in the secretions. The experience of MM. Trousseau and Pidoux already related, may be adduced as corroborative of this statement. We are told that the transpiration of Asiatics who use asafœtida daily, is extremely fœtid. Aristophanes, in his play of the "Knights," alludes to this circumstance. Vogt says that the secretions from carious ulcers sometimes smell of asafœtida, when this substance has been taken for some time.

Uses.—As before stated, asafœtida is employed by some nations on account of its flavour, and as a condiment. The Brahmins, we are told, use it against flatulence, and to correct the ill effects of their vegetable diet.

Medically, it is principally employed in certain diseases which have been usually termed nervous, or spasmodic; from which circumstance this remedy has been called an *antispasmodic*.

1.—*In hysteria and hypochondriasis.*—Few remedies have deservedly acquired such celebrity in hysteria as asafœtida. Dr. Cullen speaks in very high terms of it, and I believe the experience of most practitioners corroborates his opinion of its virtues. "I have found it," says he, "to be the most powerful in all hysteric cases; and when the presence of an hysteric paroxysm prevented medicines being taken by the mouth, I have found it, given in clyster, to be very effectual." The pathology of hysteria, and the *modus operandi* of asafœtida, are equally involved in obscurity. This remedy is also well adapted to hypochondriacal cases, especially when these are attended with flatulence.

2. *In flatulent colic of hysterical or dys-*

peptic subjects, or of infants, few remedies are more efficacious than asafetida, when the disease is unaccompanied by any marks of inflammatory action. It is given with great advantage in the form of clyster.

3. *In affections of the respiratory organs.*—As asafetida is presumed to be expectorant, it has been employed in chronic catarrhs, and is occasionally beneficial, especially in old persons. In purely spasmodic asthma—that is, in asthma unaccompanied with any appreciable organic lesion of either heart or lungs, MM. Troussseau and Pidoux speak in high terms of the effects of asafetida. Cullen, however, says he has seldom seen it of much service; and my experience coincides with his. In hooping cough it is sometimes beneficial, by diminishing both the violence and the frequency of the attacks. As a remedy for a cough it hardly deserves notice, notwithstanding the commendations bestowed on it by some physicians.

4. *In uterine affections* asafetida has been employed from a notion that it specifically affected the womb,—an opinion which is supported by the reports of Jorg's female pupils, that it brought on the catamenial discharge earlier than usual. Experience, however, has not been much in favour of the emmenagogue operation of asafetida when this remedy has been employed in diseases. "Whether it be owing," says Dr. Cullen, "to the imperfect state in which we too frequently have this medicine, or to somewhat in the nature of the amenorrhœa, I would not positively determine; but this is certain, that I have very seldom succeeded in employing the asafetida as an emmenagogue."

5. *Other uses.*—There are many cases in which the beneficial effects of asafetida have been occasionally observed and asserted, such as in worms, rheumatic and gouty affections, curious ulcers, &c.

Administration.—Asafetida is frequently given in substance, in the form of pills, in doses of from five grains to a scruple. The compound pills of galbanum contain, besides galbanum, asafetida, myrrh, and sagapenum. They may be used in the same cases as asafetida, and in the same doses. But in hysterical cases, as well as in flatulent colic, where we want an immediate effect, the asafetida is best given in the liquid form. The mixture of asafetida is one form of exhibiting it; this preparation is given in doses of from half an ounce to two ounces. The tincture of asafetida which is made with rectified spirit, may be given in doses of from half a drachm to two drachms, mixed with water, which renders it milky, or some other diluent. The fatid spirit of ammonia is prepared by

distilling hydrochlorate of ammonia, carbonate of potash, rectified spirit, water, and asafetida. Its dose is similar to the last preparation.

Galbanum officinale.

History.—Galbanum is mentioned by Hippocrates, Dioscorides, and Pliny: the two first of these writers call it *galbana*. Dioscorides says it is the product of a Ferula, growing in Syria; but the plant has not been discovered by any of the numerous travellers who have visited that country.

Botanical history.—Galbanum has for a long period been supposed to be the product of *Bubon galbanum* (fig. 151); but,

FIG. 151.—*Bubon Galbanum.*

as Mr. Don has justly remarked, this plant "possesses neither the smell nor the taste of galbanum, but in these particulars agrees better with fennel; and the fruit has no resemblance whatever to that found in the gum."

The fruit found by Mr. Don in galbanum constitutes a new genus, which he has called *Galbanum*, the species being *officinale*. It is allied to the genus *Siler*, but differs "essentially from it in the absence of dorsal resiniferous canal, and the commissure being furnished with only two." Of course a description of the plant is yet wanting.

Galbanum officinale may possibly grow in some remote and inaccessible part of Syria, as suggested by Mr. Don. Dr. Royle thinks it may perhaps be a native of the northern parts of Persia, or of Arabia.

Preparation.—Galbanum is said to be obtained "partly by its spontaneous exudation from the joints of the stem, but more generally, and in greater abundance, by making an incision in the stalk a few inches above the root, from which it immediately issues, and soon becomes suffi-

plently concrete to be gathered."—*Woodville*.

Varieties and physical properties.—Two varieties of galbanum are described.

1. Galbanum in the tear: *Galbanum in lachrymis seu granis*.—This kind of galbanum, which is very rare, occurs in distinct, round, yellow, or brownish-yellow tears. None of the tears in my collection exceed in size that of a pea. The fracture is feebly resinous, and yellow.

2. Lump galbanum: *Galbanum in massis*.—This, which is the kind usually met with in commerce, occurs in large irregular masses, of a yellow or brownish colour, and composed of agglutinated tears, some of which have a whitish fracture, intermixed with seeds and pieces of the stem of some plant.

The odour of both kinds is the same—that is, balsamic, unpleasant, and peculiar, very different to that of *asafoetida*. The taste is hot, acrid, and bitter.

Chemical composition.—This gum-resin has been analysed by Fiddechon, by Meissner, and by Pelletier. The latter chemist gives the following as the constituents:—

Resin	66.86
Gum	19.28
Wood and impurities	7.52
Supermalate of lime	traces.
Volatile oil and loss	6.34
	<hr/> 100.00

The volatile oil, which is obtained by distilling the gum-resin with water, is described by Meissner as having a specific gravity of 0.912, and being readily soluble in spirit, æther, and fixed oils. The resin is described as having the singular property of yielding an indigo blue oil when heated to 248° F., or 266° F.

Physiological effects and uses.—Galbanum is less powerful than *asafoetida*, but its operation is of the same kind. The uses of the two gum-resins are the same; the modes of exhibition are also similar. The only preparations bearing the name of galbanum in the London Pharmacopœia are the compound pills of galbanum, and the plaster of galbanum. In the Dublin Pharmacopœia there is a tincture of galbanum, made with proof spirit.

Ferula ———? (*Sagapenum*).

History.—Hippocrates and Dioscorides speak of *σαγαπηνον*. Pliny calls it *Sagapenum*.

Botanical History—The plant yielding it has been conjectured to be the *Ferula persica*, but without sufficient evidence: that it is one of the Umbelliferae there can be but little doubt. It is, perhaps, a species of *Ferula*, as stated by Dioscorides.

Varieties and physical properties.—Two kinds of *Sagapenum* are occasionally met with: the finest consists of masses made up of agglutinated, brownish-yellow, semi-transparent tears, and resembling galbanum, but having a darker colour and a more alliaceous odour. A commoner kind of *sagapenum* occurs in soft, tough masses, in which no distinct tears are distinguishable.

Chemical composition.—According to the analysis of Pelletier, this gum resin consists of

Resin	54.26
Gum	31.91
Malate of lime....	0.40
Volatile oil and loss	11.80
Peculiar matter....	0.60
Bassorine	1.00
	<hr/> 100.00

Brandes obtained 3.73 per cent. of a pale yellow volatile oil, which was lighter than water. The same authority tells us that one portion only of the resin is soluble in æther.

The effects and uses are similar to those of *asafoetida*. It is usually considered as holding a middle rank between *asafoetida* and galbanum. It enters into the composition of the confection of rue and the compound pills of galbanum.

Dorema Ammoniacum.

History.—Hippocrates and Dioscorides speak of *ἀμμωνιακόν*, which Pliny terms *Hammoniacum*. The latter author tells us that the plant yielding it is called *metopion*, and that it grows in that part of Africa which is subject to Æthiopia, near the temple of Jupiter Hammon (or Ammon), which, as well as the gum resin, received its name from *ἄμμος*, sand, on account of the sandy soil of the country.

Dioscorides says *ammoniacum* is obtained from a species of *Ferula*, which he calls *δυσουλλίς*, growing in Cyrene. Mr. Don thinks that Dioscorides "was altogether mistaken as to its native country, and that the name *Ammoniacum*, or *Armeniacum*, as it is indifferently written, is really a corruption of *Armeniacum*." I cannot agree with Mr. Don in this opinion: that a substance bearing the name of *ammoniacum* is produced from a plant growing in that part of Africa alluded to by both Dioscorides and Pliny, is proved by Mr. Jackson, in his account of Morocco; who also says, that as this *ammoniacum*, by falling on the ground, becomes mixed with a red earth, it does not suit the London market.

Botanical history.—For some years *ammoniacum* was supposed to be produced

by the *Heracleum gummiferum*; a species first described by Willdenow, who obtained it by sowing the umbelliferous fruit found in the ammoniacum of commerce. Mr. Don, however, has ascertained that the plant yielding this gum resin belongs to an hitherto undescribed genus, to which he has given the name *Dorema* (from *δωρημα*, a gift, or benefit); the species he has termed *Ammoniacum*.

Dorema Ammoniacum grows abundantly without cultivation, in Persia, in the province of Irak, over the arid plains in the vicinity of Jezul-Rhast. Mr. Don gives the following as its essential characters:—"Disk epigynous, cup-shaped; achenia compressed, edged, with three distinct, intermediate, filiform costæ. Univittate channels. Commissure quadrovittate."

Extraction.—The gum-resin is so abundant, according to Captain Hart, "that, upon the slightest puncture being made, it instantly oozes forth, even at the ends of the leaves. When the plant has attained perfection, innumerable beetles, armed with an anterior and posterior probe of half an inch in length, pierce it in all directions; it soon becomes dry, and is then picked off, and sent *via* Bushire to India and various parts of the world, and is an article of considerable export."

Varieties and physical properties.—*Ammoniacum* is brought from the East Indies and the Levant, in chests and cases. Two varieties of it are known in commerce:—

1. *Ammoniacum in the tear.*—This kind occurs in distinct dry tears, of an irregular form, externally yellow, internally white, opaque, with a vitreous fracture.

2. *Lump ammoniacum.*—This occurs in large masses composed of agglutinated tears, of a yellow colour externally, whitish internally. It is sometimes very impure, and of a plastic consistence.

Both kinds have a faint, unpleasant, peculiar odour,—a bitter, nauseous, acrid taste.

Chemical composition.—This gum resin has been analysed by Calmeyer, Braconnot, and Bucholz. Braconnot says its constituents are—

Resin	70
Gum	18.4
Gluteniform matter, insoluble in water and alcohol	4.4
Water	6
Loss	1.2
	<hr/> 100.0

The physiological effects of this gum resin are similar to, though less powerful than, those of *asafœtida* already mentioned. MM. Trousseau and Pidoux assert that in

all the cases in which they have employed it, it had no stimulant effect either local or general. "We have taken," say the authors, "two drachms of this substance at once, without experiencing any of the accidents complaisantly indicated by authors." I would remark, however, that the local irritation produced by the plaster of ammoniacum is known to most practitioners,—a papular eruption being a frequent result of the application of the agent.

The uses of ammoniacum are the same as those of *asafœtida*. The former (*ammoniacum*) is principally employed as an expectorant in chronic catarrhs and asthmatic cases of old persons; and as a discutient.

We may give this gum resin in substance, in the form of pills, in doses of ten or fifteen grains; or it may be suspended in water, as in the mixture of *ammoniacum*, which is administered in doses of one or two fluid ounces. The compound pills of squilla, and for their expectorant and diuretic effect, contain this substance as one of their constituents. The plaster of *ammoniacum* is applied to indolent tumors and chronic affections of the joints. The plaster of *ammoniacum* with mercury is employed in venereal cases; for example, to buboes, to promote their dispersion, and to venereal nodes.

Opoponax Chironium.

Theophrastus mentions four, Dioscorides three, kinds of *παραίκες*. The latter of these writers has given a good account of *Opoponax*, which he says is procured from *παραίκες ήράκλειον*.

The *Opoponax* plant, *Opoponax chironium*, is a native of the south of Europe and of Asia Minor. According to Dioscorides, whose account is probably correct, this gum resin is obtained by incisions into the root: a milky juice exudes, which in drying acquires a yellow colour.

It occurs in irregular pieces or tears, of a reddish-yellow colour, with an acrid bitter taste and an unpleasant odour.

According to Pelletier, it consists of—

Resin	42.0
Gum	33.4
Starch	4.2
Extractive	1.6
Wax	0.3
Malic acid	2.8
Lignin	9.9
Volatile oil and loss, with traces of caoutchouc	5.9

100.0

Its effects are analogous to the other foetid gums, but it is very rarely, if ever, employed.

THIRD

REPORT OF MEDICAL CASES
TREATED AT ST. GEORGE'S
HOSPITAL;

WITH

"ROUGH LEAVES" FROM HIS CASE-BOOK.

BY R. MACLEOD, M.D.

ALTHOUGH I have not yet had the satisfaction of seeing reports of the results of their practice from any other of the medical officers of the metropolitan hospitals, and although I have nothing of especial interest to communicate on the present occasion, yet I am unwilling to discontinue the contribution of my mite towards the sum of statistical information which would speedily be amassed, were any general system of constructing and giving publicity to such documents, adopted.

Many of the cases in the subjoined tables have been highly instructive, and their progress has been regarded as such by numerous gentlemen attending the practice of the hospital; but as the detail of individual cases would be fatiguing to those who did not witness them, I have confined myself to stating the general results, and adding a few examples, in which some important pathological or practical point is illustrated.

On the 1st of January, 1836, the patients in the hospital, under my care, amounted to..... 23
There have since been admitted.. 254

Total to be accounted for 277
Of the above cases there have been cured..... 168
Relieved 35
Complaints stationary 10
Transferred to surgeon 4
Dead 38
Remain under treatment 22

Total..... 277

The deaths have resulted from the following diseases, and at the following ages:—

Organic affections of the heart, with dropsy—8. Ages, 17, 20, 21, 30, 55, 56, 61, 65.
Without dropsy—1. Age, 56.
Phthisis—6. Ages, 18, 35, 48, 50, 60, 61.

Bronchitis—2. Ages, 60, 72.
Pleuritis—2. Ages, 19, 45.
Sloughy abscess of lung—1. Age, 30.
Granular liver, with dropsy—4. Ages, 32, 34, 60, 60.
Fatty enlargement of liver, without dropsy—1. Age, 49.
Acute cerebral disease, with serous effusion—3. Ages, 26, 35, 50.
Ditto, with sanguineous effusion—1. Age, 48.
Erysipelas—2. Ages, 43, 46.
Schirrus of pylorus—1. Age, 56.
Dysentery—1. Age, 55.
Disease of kidney, with dropsy—1. Age, 38.
Dropsy, apparently unconnected with organic disease—1. Age, 56.
Encephaloid tumor in pelvis, with dropsy—1. Age, 36.
Poisoning with arsenic—2. Ages, 23, 25.

The following table exhibits the ages of the 277 patients treated in 1836, and the number of deaths in each decimal period.

						Deaths.
	Under 10	5	0	
Between	10 and 20	42	3	
..	20 .. 30	80	...	5	
..	30 .. 40	67	8	
..	40 .. 50	39	6	
..	50 .. 60	...	29	8	
..	60 .. 70	12	7	
..	70 .. 80	2	1	
..	80 .. 90	1	0	
Total						38

The increase of mortality with the advance of years is rendered very striking by the above table. Of the five deaths between the ages of 20 and 30, two were from poisoning; and if we deduct these, so as to retain only cases of disease, we have 78 patients yielding but three deaths; whereas, between 60 and 70, of twelve patients, not fewer than seven died—the diseases being, organic affections of the heart, with dropsy, 2; organic affections of the liver, with dropsy, 2; phthisis pulmonalis, 2; bronchitis, 1.

CEREBRAL DISEASES—14.

Apoplexy, with hemiplegia, 3.—Cured, 2; Dead, 1.
Hemiplegia, without apoplexy on admission, 4.—Relieved, 1; Stationary, 2; Dead, 1.
Inflammatory affections of the encephalon, 4.—Cured, 3; Dead, 1.
Epilepsy, 2.—Cured, 2.
Mania e potu, 1.—Cured, 1.

Epilepsy from diseased Bone.

Of the above diseases of the brain, the only one which I think of sufficient interest to give in detail, was epilepsy, apparently resulting from the irritation produced by disease extending from the bones of the nose. For those who witnessed the intensity of the symptoms, as well as their peculiarity, in the violent and long-continued *rocking* motion of the patient, the case possessed great interest. So far as can be judged, the recovery was owing to the gradual influence produced by the sarsaparilla and iodide of potassium.

Feb. 18, 1836.—John Jones, æt. 29, had syphilis two years ago, for which he appears to have taken mercury irregularly; but gives a very imperfect account of himself. Three or four months ago a foetid purulent discharge occurred from both nostrils, particularly the left, and has continued to take place to a greater or less extent ever since. Several portions of bone have passed, and the nose is flattened from the loss of part of the vomer. Has progressively lost flesh, and become nearly idiotic. Two months ago for the first time had a fit of epileptic character, which symptom has since frequently recurred. During the last two days has constantly sat up in bed, vibrating his body from side to side like a pendulum, which he says he does to keep off the fits. Has been purged, cupped, blistered, and had a seton in the back of his neck, without relief. Pulse 100, soft; skin cool; tongue white; bowels open.

Rx Decoct. Sarsæ. ʒij.; Potassæ Hydriod. gr. iij. M. Sumatur ter die.

19th.—Had a fit of great violence last night, and another this morning. Complaints of pain in the left temple, and the eye of that side is injected. Mouth slightly drawn to the left; rocking motion more violent than ever.

Cucurbit. Cruentæ temporibus, et abstrah. sanguis ad ʒxij.

Calomel gr. iij. h. s. Haust. Sennæ cras mane.

Repr. Decoctum Sarsæ ut antea.

20th.—Head relieved; rocking less violent.

22d.—More pain in temple and forehead; is rocking violently, and says he is going to have a fit.

Hirudines xij. tempori sinistro et fronti quamprimum. Rep. medicamenta.

23d, 24th, 25th, 26th.—Violent epileptic fits daily. Mouth more drawn to left side. Leeches repeatedly applied. A blister to

left temple. Freely purged. Sarsaparilla and hydriodate of potass continued.

From this time the fits gradually became less frequent and less violent, and had ceased by the 5th of March. He continued, however, to have a purulent discharge from the nose, and attacks of pain in the forehead and temples, with giddiness; for which he had leeches repeatedly applied, and several blisters, always with relief. The sarsaparilla and hydriodate of potass were continued, under which his whole aspect changed remarkably: he gradually gained flesh and strength, and his intellect became much improved.

May 16th.—A considerable quantity of foetid purulent matter, with blood, came from the right nostril, but no bone could be detected. From this time the discharge diminished, and he was dismissed June 12, having had no fit for three months, and having taken nothing but opening medicine during the last fortnight.

P.S.—I saw this patient in December, 1836. He had been employed since his discharge as a labourer; he had had a fit after working in the fields during the autumn, for which he had been cupped with relief, but still had occasional pain in the head.

SPINAL DISEASES—6.

Paraplegia, 3.—Cured, 1; Relieved, 1; Dead, 1.

Paralysis of fore arms, 3.—Relieved, 2; Stationary, 1.

VARIOUS NERVOUS DISEASES—30.

Hysteria, 17.—Cured, 10; Relieved, 5; Remaining, 2.

Chorea, 7.—Cured, 6; Remaining, 1.

Paralysis agitans, 1.—Much relieved, 1.

Neuralgia, 2.—Cured, 1; Relieved, 1.

Hypochondriasis, 3.—Relieved, 2; Stationary, 1.

DISEASES OF RESPIRATORY ORGANS—35.

Phthisis pulmonalis, 14.—Relieved, 8; dead, 6.

Bronchitis, 8.—Cured, 5; dead, 2; under treatment, 1.

Laryngitis, 1.—Cured, 1.

Pulmonitis, 4.—Cured, 3; dead, 1.

Pleuritis, 2.—Cured, 2.

Hæmoptysis, 3.—Cured, 3.

Sloughing abscess of lung, 1.—Dead, 1.

Empyema, 1.—Under treatment, 1.

Whooping cough, 1.—Cured, 1.

The case of empyema in the above list is one of great interest. The patient has had the operation of *paracentesis thoracis* performed, and many pints of matter have been removed: the aper-

ture is still open, and discharges freely. I shall publish the case when I can give the result, concerning which I am far from being sanguine.

One of the cases of phthisis was remarkable, owing to the existence of an external fistulous opening in the parietes of the chest. It is problematical how far this was dependent upon the action of the tartar emetic ointment, which appeared to have been very freely used.

Case of Phthisis, with fistulous opening in the parietes of the chest.

John Rivier, æt. 61; admitted May 11, 1836. About eighteen months ago was attacked with cough, which in the first instance was accompanied by expectoration of blood. He appears to have been under the care of several persons, and to have been subjected to a variety of treatment, but particularly in the form of counter-irritation, by means of tartarized antimony applied to the chest. States that six months ago, consequent on the applications made to his chest, two small swellings formed externally, near to each other, and two inches below the left nipple, which were punctured with a lancet, and some matter evacuated. One of these apertures never healed, and between four and five weeks ago he became sensible of air passing out through the opening when he coughed. At present there are five fistulous apertures, situated at the lower part of sternum, and left side of the chest anteriorly, from which matter oozes, and air may occasionally be seen to raise the pus in little bubbles, and heard to blow through the apertures as he coughs. The chest for some inches round the fistulous openings is dull, but respiration is heard in nearly the whole of right lung, and in the left, a little above the highest of the apertures. Has habitual cough, accompanied by purulent expectoration. Pulse 90, feeble. Considerable emaciation and nocturnal perspirations.

21st.—Gradually sank, and died on the evening of the 19th.

Autopsy.—The external openings on the chest were found to lead to a considerable irregular cavity, formed by the undermining of the integuments. On removing these, the ribs and cartilages were seen to be denuded and rough at various points. The ribs were sawn through on both sides, so as to elevate the whole of the anterior parietes of the chest: on doing this the anterior and lower portion of the left lung was found to be firmly adherent to the inside of the ribs. The lung was cut through, so as to leave the adherent por-

tion *in situ*. A probe was now made to travel over the external surface where the integuments were undermined, when it found its way into the adherent lung. It was cut down upon, and found to have entered a bronchial tube through an ulcerated opening, which presented between the fifth and sixth ribs, near to left edge of the sternum.

The lungs on both sides contained numerous tubercles, many of which were clustered together, and formed into small vomicae.—The preparation is in the museum of the hospital.

DISEASES OF THE HEART AND ITS APPENDAGES—24.

Acute pericarditis, 6.—Cured, 4; relieved, 1; dead, 1.

Various organic diseases of the heart, with dropsy, 16.—Cured (as regards the dropsy), 6; dead, 6; stationary, 1; under treatment, 3.

Organic diseases unaccompanied by dropsy, 2.—Relieved, 1; under treatment, 1.

Rheumatic Pericarditis—Maniacal Delirium.

While I believe that the assistance to be derived from the use of the stethoscope has been greatly exaggerated, and that even now some profess to discover by it many things which are clearly indicated by other means, yet there are unquestionably certain cases in which auscultation, mediate or immediate, gives a precision to diagnosis which it could not otherwise attain. The following appears to me to be an example of this, being one in which I believe the pericardium to have been the seat of the actual disease, although the cerebral disturbance appeared much more strongly marked to the observation of the bystanders. If this opinion be correct, the importance of the fact as regards the treatment is too obvious to require illustration, leading as it did to the steady and continued use of mercury, the only agent, so far as my experience goes, by which pericarditis under similar circumstances can be overcome. The fact of the symptoms in inflammation of the pericardium being chiefly, or even exclusively, referred to the head, is not new, a case of this kind having been recorded by M. Andral in his *Clinique Médicale*, and reference also made to it by M. Rostan; it was, however, still more explicitly mentioned by Dr. Latham, in one of his lectures published in the MEDICAL GAZETTE so early as January, 1820.

It is an important fact, then, in a practical point of view, that rheumatic pericarditis may take place without any such pain, or other uneasiness, being referred to the chest, as to lead the patient to complain of it; so that it may escape the attention of the practitioner unless he be aware of the danger, and on the alert to detect it. With some it may possibly be matter of question whether, in the case of Mary Hall, which I subjoin, the brain was not affected with inflammation, or other disease, implying more than mere sympathetic disturbance of function. My belief that it was not, depended upon my previous knowledge, that cerebral affections of the severest kind may be entirely dependent upon inflammation of the pericardium, and which was proved by the local signs to have taken place in the present instance; while there was no heat of scalp, injection of the eyes, or intolerance of light. Again, in Andral's case there were delirium, convulsive twitchings, tetanic spasms, coma, and paralysis of the upper extremities; yet all this was proved by dissection to have depended entirely on pericarditis, without a vestige of disease in the head.

Jan. 20th, 1836.—Mary Hall, ætat. 27, has suffered from rheumatic pains in various joints for about a month. A week ago the knees became more particularly affected, having been swollen and red. The day before yesterday the hands and wrists were seized, both being at present very painful, and somewhat swollen. Considerable fever of the common rheumatic character.

Fiat Venesection et Mitt. Sanguis, ad ℥xii.; Calomel, gr. iii. hora somni. Haust. Sennæ, cras mane.

21st.—Pain relieved. Blood exhibits a large, firm, buffy, cupped coagulum.

Repr. Venesection et Medicamenta.

22d.—Scarcely has any pain remaining; fever much reduced. Blood no longer buffed.

Pulv. Saponis cum Opio, gr. v. om. nocte. Haust. Sennæ cras mane.

25th.—Has continued free from pain, but her expression is rather anxious, and she was faint yesterday. To day, on being questioned, acknowledges that she has some uneasiness in the region of the heart, in which situation pressure between the ribs gives pain. Slight dry cough. Nothing abnormal in the sounds of the heart or re-

spiration can be perceived. Pulse 100; skin hot; bowels sluggish.

Fiat Venesection ad ℥xii.; Calomel, gr. iii. cum Opio, g. i. quamprimum et hora somni.

Haust. Sennæ cras mane.

26th.—Does not make any complaint, but she shrinks from pressure in the region of the heart. On applying the ear to-day, a rubbing sound can be distinctly perceived under and to the left of the sternum, particularly in a line with its centre. Pulse as yesterday; blood cupped and buffy; bowels open. More faintness and anxiety, with some incoherence.

Applicentur Hirudines, xvi. sterno. Calomel, gr. v.; Opio, gr. ½. M. f. Pilula. Sumatur 4ta quaque hora, ad tres vices et deinde repetatur per re nata.

Haust. Sennæ cras mane.

27th.—Denies having any uneasiness in the chest. Is at present lying on the right side. On making her turn on the back, so as to examine the heart as before, the pulsations are found to be more obscure, and convey the idea of being more distant. No rubbing sound.

Emplast. Lyttæ sterno. Repr. Pil. 6ta quaque hora, et Haust. Sennæ cras mane.

28th.—Again admits that she has some pain in left side of chest. Seems indifferent as to what posture she lies in. Is very restless, with constant delirium. Fully under the influence of the calomel. Pulse about 100; but neither this nor the heart's action can be accurately examined, on account of the extreme restlessness. Urine rather scanty. Passes her evacuations in bed.

R. Tinct. Digitalis, ℥vi.; Tinct. Lyttæ, ℥xx.; Tinct. Scillæ, Spirit. Ætheris Nitrici, a. 3ss.; Aquæ, 3x. M. f. haustus, 6ta quaque hora sumenda. Omittr. Pilulæ.

30th and 31st.—Constant delirium and unceasing jactitation, with frequent efforts to get out of bed, so that it has been requisite to put on a strait waistcoat. No affection of the pupil, or apparent dislike to light. Pulse about 100, feeble; urine more abundant, but continues, with the alvine evacuations, to be passed involuntarily. Mouth still sore, but mercurial action receding.

Repr. Haustus sine Tra. Digitalia.

Feb. 1st and 2d.—Scarcely any perceptible change in the general aspect of the case. During a few minutes' quiet the stethoscope was applied over the heart as she lay on her back. The pulsations were

to be feeble, distant, and inter-
Rather strong pulsation per-
the carotids, and regurgitation in

Malignant tumor in pelvis, 1.—Dead, 1.

The case which I regarded as in-
flammation of the uterus is subjoined.
I have reason to believe that the symp-
toms originated in immoderate sexual
intercourse, without regard to the pre-
sence of the menses.

Hysteritis.

Sarah Constantine, ætat. 28.

March 12th, 1836. Was married a
month ago. Complains of very severe
constant pain between the pubes and sa-
crum, extending over the lower part of
the abdomen, down the thighs, and across
the loins, aggravated by firm pressure
in the pubic region. Pulse 106, sharp;
skin hot; tongue white; considerable
thirst; bowels confined. Menstruated
copiously a fortnight ago, the discharge
having suddenly ceased last week, cotem-
poraneously with the supervention of the
present symptoms.

Fiat Venesection, ad 3xii.; Hirudinea, x.
regioni pubis; Haustna Salin.c.; Mag-
nesiæ Sulphatis, 3i. 4tis horis.

13th.—Pain unabated; bowels free. Blood was a large firm coagulum, but without buff.

Repetantur Hirudines. Fetus Papaveris abomini.

R. Calomel, gr. iii.; Opii, gr. i. M. fiat Pilula, 8va q. q. hora sumenda. Ol. Ricini, ʒss. cras mane.

16th.—Has progressively improved since last report, having but little pain, and bearing pressure with slight inconvenience.

The mercurial was continued in diminished doses till the 28th, when her mouth became affected. She was discharged on the 1st of April, cured.

DISEASES OF THE ARTICULAR AND FIBROUS SYSTEMS—56.

Ditto (chronic), 20.—Cured, 14; relieved, 6.

Gout, 1.—Cured, 1.

Periostitis, 3.—Cured, 3.

Further experience has tended to confirm the observations I made in my last report, on the superiority of bleeding and purging over every other method, in treating acute rheumatism at its onset. It is the only treatment by which I have seen the disease at once speedily and effectually arrested; but it is necessary to put it in force boldly, and at a very early stage of the attack, to produce this result. Of the above cases of acute rheumatism, several had more or less affection of the pericardium, but those only have been entered under the head of pericarditis, in which the inflammation of that part constituted the prominent part of the attack.

One of the cases of acute rheumatism ended fatally, not by affecting either the heart or membranes of the brain, or the pleura (the first of which is a very common, and either of the latter an occasional event), but by giving rise to suppuration in the joints chiefly implicated. Of this I have seen four cases, and therefore look upon it as an occurrence much less rare than medical authors generally would lead us to suppose. I believe, too, that such cases are marked by peculiar characters in the general disturbance, and by extreme obstinacy in the local affection. In the instance which is subjoined, I gave it as my opinion, three weeks before the event occurred, that the patient would die, and that suppuration would be found.

Acute Rheumatism ending in Suppuration.

George Coombs, æt. 31, admitted November 23, 1836, at which time he stated that he had suffered from pains in his limbs for about a month.

He had then no pain except in the left knee, where it was still severe. There was no swelling nor redness, and he could bend it without much uneasiness, but complained greatly when the limb was straightened. His pulse was 90, soft; tongue clean; bowels open; and altogether there was but little general disturbance.

He was blistered just above the knee; took Dover's powder at night, and was purged.

By the 29th he had little pain remaining; took his food, and appeared so well that it was in contemplation to discharge him.

Dec. 1.—Had a rigor yesterday, followed by heat and copious sour sweating. To-day has pains in his limbs generally, particularly in both knees and shoulders; headache; pulse 100; skin hot; tongue white and clammy.

Calomel, gr. v. h. s. hac et crastina nocte. Haust. Sennæ omni mane.

8th.—Febrile symptoms subsided on the 3d, at which time rather a copious eruption of herpes labialis appeared. Pains in the joints above-named, however, continued, for which he had

Pulv. Ipecac. Comp. gr. x. om. nocte, and appeared to be going on well till last night, when he had another rigor, with nausea and vomiting. Pulse 100; skin hot; tongue slightly furred, dry. Complains much of the pain in the limbs.

Calomel, gr. iii. sexta quaque hora. Haust. Sennæ, omni mane.

15th.—Has progressively improved. Gums sore; pains entirely gone; no stiffness or other remains of the affection of left knee, on account of which he was admitted.

Extract Colocynth Comp. gr. v. om. nocte. Omitt. alia.

19th.—Had an attack of shivering the night before last, since which time he has suffered from pain in both knees, particularly the right. Has also some pain under the sternum. No abnormal sound to be perceived. Pulse 108; tongue brown and clammy; mouth well.

Hirudines xii. parti sterni inferiori. Calomel, gr. iii. quamprimum et hora somni. Haust. Sennæ cras mane.

22d.—Pain of chest relieved; other symptoms unchanged. Has had gr. ii. of

calomel every six hours. Gums beginning to be affected. Great pain in the limbs generally; pulse 100, throbbing.

Rep. Calomel cum Opii, gr. $\frac{1}{2}$, sexta quaque hora.

24th.—Left ankle painful and swollen, with some redness of the integuments; also some swelling of left elbow, with redness extending about two inches up the outer part of arm; much anxiety of expression; pulse 116; tongue loaded; gums have a perceptible red line, but not to a greater extent than two days ago; bowels open.

Rep. Pil. Calomel c. Opio, ut antea.

R. Liq. Acet. Ammoniae, 3ij. Oxy-mel, 3j. Aquæ, 3ix. M. sumatur 6ta quaque hora.

26th.—Knuckle of left middle finger red, swollen, and very tender.

28th.—Pain over the whole of left arm, from the middle finger (the first joint of which is very red and much swollen) up to the shoulder.

31st.—Swelling of the finger-joint diminished, and that above elbow has disappeared, but still has considerable pain up the arm and in both shoulders; pulse 100, jerking; copious acid perspirations continue.

This concludes the year, and with it the period to which the present report extends. I may, however, complete the case by briefly stating that the patient, on the subsidence of the affection of the left hand, complained next of the right knee, which became swollen, the synovial membrane being evidently distended, while the limb was habitually retained in a half-bent position. He had opiates administered, and light nourishment, while his bowels were kept gently open. He continued to suffer great general distress and anxiety, which, however, never at any time was attended with delirium. He gradually sunk, and died on the 12th of January.

The body was examined next day. The right knee was distended and fluctuating; on opening it, about half a pint of thin purulent matter, with some flocculi, was evacuated. The cartilages were entire, and of healthy appearance; the synovial membrane was redder than natural, and pushed upwards under the quadriceps muscle, by the effusion it had contained. The metacarpal joint of the finger which had suffered, was next opened. The flexor tendon was softened, and seemed sodden, and deprived of its silvery lustre (it had been observed before death, that he

never extended the finger, even after the inflammation had subsided); the articular surfaces red, roughened, and smeared with a thin layer of pus. The left ankle, which seemed to have been the third in the degree of suffering, was next examined, but no morbid appearance observed. The viscera generally looked pale, and were very soft. Neither the pericardium nor heart had any morbid change, except that there was a little thickening of the mitral valves. There were from two to three ounces of fluid in the ventricles of the brain.

EXANTHEMATA, AND ACUTE DISEASES OF THE SKIN—9.

Erysipelas of face and head, 4.—Cured, 2; dead, 2.

Purpura hæmorrhagica, with apoplexy, 1.—Dead, 1.

We are told in books, that when patients die of erysipelas of the head, the membranes of the brain are generally inflamed. Is this the fact? That it frequently is not so, I am convinced; having repeatedly examined such cases without finding any thing of the kind. The two fatal cases entered in the above list are instances of this, the brain and its membranes having been perfectly healthy in both.

The case of purpura hæmorrhagica was interesting; chiefly on account of the post-mortem examination, which shewed the hæmorrhagic tendency to be so great that some even of the articular cartilages had participated in it. Yet it is curious that, on the body being taken to the dissecting-room, which was afterwards done, the injection did not show any disposition to become extravasated.

Purpura ending in Apoplexy.

James Glennerson, ætat. 48, labourer.

Admitted, under the care of Mr. Babington, October 21st, at which time the principal symptom was hæmorrhage from the mouth; the gums and tongue being covered with purple bleeding spots, and the trunk and limbs having numerous spots of purpura scattered over them. He passed blood with his urine—some by stool. He took sulphuric acid, and afterwards sulphate of quina, together with laxatives, and had a gargle of chloride

of soda, the fœtor of the mouth being extremely offensive.

He came under my care on the 27th, at which time the bleeding from the mouth had ceased, and the spots were dying away. He continued apparently convalescent, and the purpura had almost entirely disappeared, when—

Nov. 10th, the spots were observed to show themselves on various parts of the body, particularly the abdomen and lower extremities. There were also several on the tongue, and from these the blood again began to ooze rather freely. Pulse 92, full and strong; skin hot; tongue clean, except at the site of the purpura; bowels open from medicine.

Mitr. Sanguis, ad 3x. Habeat Acid Sulph. Dil. m̄x. tertia quaque hora ex aquæ pauxillo.

11th.—Blood drawn yesterday exhibits a very large coagulum, the serum appearing to have separated but imperfectly; buffy coat half an inch thick. Hæmorrhage from the tongue has almost ceased; pulse and skin as yesterday; bowels have not acted to-day.

Calomel, gr. iii. quamprimum. Haust. Seunæ post horas tres et cras mane nisi prius responderit alvus.

12th.—Bowels freely purged yesterday after the visit. Had a recurrence of hæmorrhage from the mouth last night, and lost nearly half a pint of blood. Pulse 104, bounding; skin hot. Tongue has only one or two spots upon it, and is but little swollen: the bleeding comes chiefly from the gums.

Fiat Vene-ectio ad 3x. Habeat. Ol. Terebinthinæ, 3ss. quamprimum et cras mane, ex Aquæ Menth. Virid. 3iss. Gargarisma ex Chloride Sodæ.

13th.—Blood exhibits a very thick buff (above half an inch); serum scarcely separated from the coagulum; much less bleeding from the mouth; bowels freely purged, and motions dark, apparently from the admixture of blood; pulse 93, softer; skin cooler.

14th.—A good night; little or no bleeding from the mouth; pulse 100, full, but soft; bowels have acted twice moderately, motions still dark; spirits depressed—almost hysterical; begs earnestly for meat and porter, which request has not been complied with.

Rep. Ol. Terebinth. cras mane.

15th.—Mr. Hammerton (the apothecary of the Hospital), was sent for a little after midnight, when he found him in an apoplectic fit: he opened a vein, but without avail; the patient expiring in little more than half an hour from the first appearance of the cerebral symptoms.

Autopsy.—Body pale, with numerous purple spots. On removing the skull cap, a small quantity of serum exuded from beneath the arachnoid membrane; the convolutions were much flattened, and at the anterior part, imbedded in the arachnoid, were two or three flat bony deposits, of various sizes, the largest not exceeding the circumference of a shilling. On slicing off the lobes, a coagulum, about half the size of a pea, was found imbedded in the substance of the left hemisphere. The ventricles contained a considerable quantity (3iiss. or iiij.) of serum. At the base of the brain, covering the cerebellum and medulla oblongata, there was a thin layer of extravasated coagulated blood; this was traced into the right lobe of the cerebellum, where it formed a coagulum about the size of a large walnut, imbedded in, and breaking down, its substance.

The spinal marrow throughout appeared natural.

The lungs were healthy; some purple spots in the pleura costalis. The heart of normal size and consistence, but having some purple spots on its outer surface. The aorta thin and brittle, so as to be easily torn. The stomach had an ecchymosed appearance externally; internally were numerous stellated reddish spots. The liver healthy; no spots. The spleen rather above the usual size; nothing remarkable in its appearance. (A minute supplementary spleen, about the size of a chestnut.) Bowels spotted here and there throughout their whole extent. Kidneys presented stellated spots externally: the pelvis of each of a deep purple colour, apparently from blood extravasated beneath the lining membrane.

The right knee being cut into, shewed several purple spots on the synovial membrane.

The body being unclaimed, was carried to one of the anatomical schools, and dissected. The injection ran well, and no extravasations were observed to have been occasioned by it. On cutting down upon and examining some of the spots of purpura, they were found to consist of a minute layer of extravasated blood on the surface of the cutis.

FEVERS—23.

Intermittent, 5.—Quotidian, 2; tertian, 3; cured, 5.

Continued, 18.—Cured, 16; convalescent, 2.

During the year 1835, eleven patients were admitted under my care for continued fever; of whom one died. In 1836, eighteen have been treated, among whom there has been no death: the two years thus giving only one death in twenty-nine cases. This may

be regarded as a small rate of mortality; but it must be added that the type of fever has not generally been severe. During the last two months of 1836, however, the cases became more formidable, some of them being accompanied by petechiæ, with great debility, and local complications. Without presuming to offer an opinion on other methods of treatment, which I have not seen tried on a scale sufficient to enable me to judge of them, I may be allowed to say that while so large a proportion of the patients do well, I find no temptation to abandon the practice I have long pursued of giving mild mercurials, and regulating the bowels by gentle laxatives. The coincidence, too, of the gums exhibiting the mercurial action, and the symptoms subsiding, is too constant to be the result of accident, and must depend either upon such action overcoming the fever, or the subsidence of the fever allowing the mercury to produce its peculiar effect. Supposing it to be only the latter, the results shew that the mercury does not prevent this favourable change from occurring.

**CASE OF AN
EXTENSIVE ENCYSTED HEPATIC
ABSCESS, WITH HYDATIDS.**

To the Editor of the Medical Gazette.

SIR,

ONE frequently hears the notion broached that hydatids exert a peculiar malignancy over the body in which they are situated; but the length of time which we may presume to have elapsed, in the following instance, from the formation of the primitive hydatid, to the period when they had accumulated a thousand-fold (the patient, meanwhile, labouring under no affection which might not have been ascribed to the mere bulk and situation of the tumor), as far as an isolated case is valuable, disproves the assertion.

I had the opportunity afforded me of assisting at the post-mortem examination, through the kindness of Mr. Robert Clarke, a practitioner of this town, whose patient the woman had been from the commencement to the termination of her malady.

I am, sir,

Your most obedient servant,

R. H. ALLNATT, M.D.

A young woman of respectable connexions, residing at South Moreton, Berkshire, aged 29, of strumous diathesis, who had long been suffering under anomalous symptoms, the cause of which was not apparent, was suddenly attacked with rigors, and distressing dyspnoea, nausea and vomiting, accompanied by a swelling, and a sense of great weight and pressure at the pit of the stomach. She had for some time previously been unable to lie in particular postures, and had suffered darting and lancinating pains which were principally referred to the posterior region of the thorax.

As she had been for a considerable period labouring under ill health, it was deemed unadvisable, in the present instance, to resort to harsh measures of treatment. Mild antiphlogistic remedies were therefore ordered, and a few leeches applied with a view of affording temporary alleviation, but to no purpose; the patient lingered for two days and died.

Inspectio cadaveris.—The body, externally, presented an emaciated appearance. A large circumscribed fluctuating tumor was discovered, situated in the epigastrium, bearing evident signs of recent inflammation. On cutting down to the liver it was found that the great left lobe was completely gone, and its place occupied by an encysted tumor of vast extent; the lateral and posterior walls, formed of the peritoneal covering of the lost lobe, were so morbidly thickened and indurated that they had assumed a fibro-cartilaginous structure. There was no vascular turgescence except at the base of the external tumor, and at this point the peritoneal and muscular coverings were so thin that a superficial incision, after turning back the dermal integuments, entered the abscess. It having been found impossible to dissect the sac from its attachments entire on account of its bulk and the extreme tenuity of its anterior walls, a large incision was made

into it as it lay *in situ*. The effused fluid was exceedingly abundant, varying in colour and consistence as it occupied the upper or more depending portions of the abscess, and was filled with hydatids of various gradations of growth, from the size of a pea to the diameter of an inch and a half. Several of these acephalocysts were empty, and looked like flocci of coagulable lymph; others were flaccid, being half filled with a limpid fluid, and resembled flattened spheroids: these appearances I attribute to the length of time which had elapsed since the death of the woman, a period of sufficient duration to cause the partial decomposition of many of these thin and filmy bodies. It was the opinion of Mr. Robert Clarke, the gentleman who conducted the examination, and of his father, who was also present, that the tumor contained, at the most moderate computation, *considerably upwards of a gallon of effused fluid*, several wash-hand basins full having been successively carried away and emptied by the attendants.

The remaining (right) lobe of the liver was turgid, and its proper structure in such a state of *ramollissement* that it broke down under the slightest pressure. The gall-bladder, which was apparently untouched by the disease, contained a small quantity of thin, semi-transparent, unhealthy looking bile.

The thorax presented abundant traces of the former existence of disease. The parenchymatous tissue of the lungs was healthy, but the pleura pulmonalis adhered so firmly to the costal pleura that it required considerable effort to detach them. The heart, which was flaccid and slightly hypertrophied, adhered in places to the inner membrane of the pericardium; and the external layer of this investing membrane had frequent points of attachment to the diaphragm and mediastinum.

REMARKS.—The foregoing case is chiefly interesting as it shows the enormous magnitude a tumor of the internal organs may attain, and the important lesions vital structures may undergo, without giving rise to an equivalent urgency of symptoms. Dr. Tweedie, upon the authority of Abercrombie, states that “no less than *four pounds* of purulent matter have been found in a single abscess of the liver”; but here we have a tumor containing double,

may treble that quantity, and yet the patient continues in comparatively an uninjured condition for a considerable length of time. Mr. Cæsar Hawkins, speaking of encysted tumors, says, “that wherever hydatids are situated, little suffering is experienced except from the bulk of the tumor, as long as there is no great inflammation”; but he is here alluding, I presume, to the common encysted tumor, formed of a single hydatid. In the liver, however, the case is altered, for he says “the peculiar situation of these tumors may render them fatal at an earlier period than they otherwise would have been.” I can only therefore account for the enormous extent of the tumor in question causing so little comparative inconvenience from its magnitude, by the apparent fact, that as the fluid became slowly deposited, the consequent distension of the sac produced a gradual absorption, and eventually usurped the entire situation of the left lobe of the liver.

Wallingford, Jan. 28, 1837.

INFLUENZA;

NATURE AND TREATMENT OF THE PRESENT EPIDEMIC.

To the Editor of the Medical Gazette.

SIR,

THE immense number of persons labouring under the present prevailing epidemic, now raging in every part of England and Scotland, as well as on the Continent, has perhaps scarcely ever been exceeded; while in many cases the violence of the symptoms has caused a fatality as great as that by any scourge which has visited us for many years.

It may be difficult to refer this disease to any definite cause, or to prove whether it is occasioned by a morbid poison existing in the atmosphere, or depends on the many great and sudden changes of temperature that have taken place in the course of the few last months. But there can be no doubt of its being the duty of every medical man to determine by experiment the best mode of treating this affection, and as a vast number of patients have been daily falling under my care, I have been

led to try the comparative effects of bleeding and of withholding the lancet, and to send you the results.

The disease usually makes its invasion with alternating chilliness or shiverings, and flushings of heat, with a sense of extreme languor, and pain in the forehead and limbs, followed by a tenderness and fulness of the eyes, accompanied with a copious discharge of thin fluid; then supervene sneezing, sore throat, hoarseness, and a dry cough, a feeling of constriction across the chest, with difficulty of breathing, with pain in the back, depression of spirits, and great prostration of strength. The tongue is generally clean and often moist, the pulse quick and jerking, afterwards small and feeble, and the skin is for the most part in a state of perspiration; vertigo and delirium are not uncommon, neither are hæmoptysis and epistaxis; nausea, vomiting, and pain in the bowels with diarrhœa, are also occasionally present.

The pain in the forehead, dry cough, and delirium, were often of such extreme urgency, as that active depletion appeared not only to be justifiable, but essential to the safety of the patient, and I accordingly selected five cases in which I employed the lancet with no sparing hand. The bleeding, however, was quickly followed by an alarming and dangerous prostration of strength, with little improvement in any symptom, and at best by a very protracted convalescence, so that I was induced to abandon the lancet, and to adopt a more simple mode of treatment: in a series of cases of equal severity and nearly similar in every particular, I therefore, now prescribed, as in the former instances, Hydrarg. Chloridi*, gr. ij.; Extr. Coloc. Co., gr. viii. statim, and a draught every four hours consisting of Syr. Papav., Misturæ Acaciæ, aa. 3j.; Liq. Ammon. Acet. 3ij.; Mist. Camphor, 3i; while pediluvia, blisters, and mustard cataplasms, were used as occasional adjuvantia; at the same time enjoining restriction to a low diet for two or three days, then moderate and well-regulated support.

I have thus treated five hundred and eighteen cases with perfect success, for I am satisfied the patients have recovered with much less discomfort, at far less expense to the system, and within a much shorter period of time,

than when the lancet was used. Indeed the convalescence may be said to have been in general fairly established on the fifth day in the last series of cases, while on the contrary, in that where venesection was performed, all the phenomena became greatly aggravated, and the patients were in fact unable to leave their beds for ten or twelve days, and sometimes even longer.

It is remarkable also, when the symptoms have so nearly resembled those of arachnitis, peripneumonia, pleuritis, or enteritis, which was by no means infrequent, as almost to warrant these several diagnoses, they have universally yielded to the remedies I have specified, without the loss of blood, and have neither been followed by the ordinary consequences of inflammation, nor with the distressing collapse and lengthened illness of the patients in whose cases bleeding was resorted to.

The greater advantages which have resulted from abstaining from bleeding in these cases, almost inclines me to adopt the hypothesis, that this disease does not depend on mere changes of temperature, but on the existence of one of those many atmospheric poisons which so often influence our health: especially as the practical result seems to be in accordance with those principles I have so often advocated through the medium of your journal: but I beg to add a case which involves no hypothesis, and which is distinctly in proof of bleeding very considerably aggravating the effects of a poison demonstrably introduced into the system.

On Wednesday, Jan. 18th, at one o'clock P.M. Mr. Belcher upon entering an apartment where ipecacuanha powder was being used for pharmaceutical purposes, was immediately seized with the most urgent dyspnœa, with a sense of constriction across the chest, accompanied with violent and convulsive cough, which, together with the sneezing, continued for some time, until at length his countenance became anxious and livid; his eyes were suffused, and he complained of a dry, burning sensation in the fauces, amounting almost to suffocation; his pulse was rapid. He was instantly removed from the room, and I prescribed, Sp. Ætheris Sulph. Co. 3iss. ex Mist. Camph. statim; which I directed to be repeated at short intervals, until the symptoms were relieved. At the end of twenty minutes

* Calomel.

there was a marked improvement, his breathing first becoming freer, and all the other symptoms gradually subsiding, so that in the evening he was quite well, and resumed his ordinary occupation on the following morning.

This singular idiosyncrasy has manifested itself in this individual as many as a dozen times, when he has always been bled, and subsequently blistered. Dr. George Gilbert Currey was the first to recommend bleeding in Belcher's case; the practice has since been repeated, and he has invariably been confined to his room for four or five days; indeed, I treated him myself by bleeding, under the same circumstances and with like result twelve months since.

A German physician, Dr. Prieger, has published a remarkable case of a person, who, in consequence of inhaling the dust of ipecacuan powder, was attacked with a sense of tightness in the chest, vomiting, and soon after an alarming sense of suffocation, from tightness in the throat. When these symptoms had continued several hours, and bleeding had been ineffectually resorted to, the uneasiness in the throat was removed after the use of a decoction of uva-ursi and rhatany root: but the dyspnoea remained several days*.

My case of ipecacuanha, as it appears to me, strongly illustrates a doctrine long inculcated by Dr. Williams, with respect to this class of diseases, and, as far as my experience has gone, acted upon with admirable effect by that physician.—I remain, sir,

Your faithful servant,
HENRY BULLOCK, M.R.C.S.

St. Thomas's Hospital,
Jan. 28th, 1837.

ACCOUNT
OF AN
ANOMALOUS DISTRIBUTION OF
THE BRANCHES OF THE AORTA,
AND AN UNUSUAL COURSE OF THE
RIGHT SUBCLAVIAN ARTERY.

To the Editor of the Medical Gazette.

SIR,
SHOULD you deem the following account of an anomalous distribution of the ar-

teries arising from the arch of the aorta worthy of insertion in your valuable journal, you will much oblige

Your obedient servant,

FRANCIS HIRD,
Late Secretary to the Dublin Medical-
Surgical Society.

Finsbury-Square,
Jan. 26, 1837.

The subject of this anomaly was a male, of middle age, rather tall, and of muscular frame. The irregularity in the distribution of the arteries was not confined to the cervical region, there being a high division of the brachial artery in the left upper extremity: the left hepatic artery arose from the abdominal artery itself, and there were two renal arteries on each side; but the irregularity to which I wish to draw attention was from the transverse portion of the arch of the aorta.

From this portion of the aorta two branches were given off, the larger arising from that part of the artery which in the regular distribution gives origin to the arteria brachio-cephalica: the other was the left subclavian. The first of these, a thick trunk a little more than an inch in length, was directed towards the left side of the neck, and bifurcated about the middle of the trachea into the arteria brachio-cephalica and left carotid, which arteries subdivided as usual, but the situation of the former, and its continuation, the right subclavian artery, were greatly altered in relation to the surrounding parts: they were situated much higher than usual; the subclavians passed anterior to the scalenus anticus muscle—a course that has very rarely been observed. This abnormal distribution of arteries is, with a slight modification, the normal conformation observed in a great many animals occupying an inferior station in the scale of gradation: in several of the quadrumana, of the glira, in the lion, hyæna, bear, marmot, guinea pig, &c.

There was a small triangular space formed over the front of the trachea, bounded on the right by the arteria brachio-cephalica, on the left by the left carotid; its apex being formed by the decussation of these arteries, and its base by the thyroid gland.

The vertebral artery was larger than natural, remarkably superficial, and ascended as high as the second cervical vertebra before entering the foramina in their transverse processes.

* Rust's Magazin für die gesammte Heilkunde, 32, 182.

The phrenic nerve descended along the outer margin of the scalenus anticus muscle, crossed the subclavian artery at a right angle, lying immediately upon it, still situated at the external border of the muscle.

An accurate acquaintance with the abnormal distribution of parts appears to me to be almost as indispensably necessary to the operative surgeon, as a knowledge of their natural arrangement. It is no light thing to have life intrusted into our hands; the rules of our art are not invariably precise and certain; and it is the imperative duty of every one to avail himself of every opportunity of acquiring practical knowledge. The possibility of such a distribution as I have mentioned points out at once how necessary it is to be cautious in performing the operation of tracheotomy: the life of the patient probably depends on the direction of the edge of the knife, for in the natural arrangement, in which I have seen several operations performed with the cutting edge of the knife, in a case like the one I have mentioned it might prove destructive to life. Hence the necessity of establishing a general rule of cutting from below upwards.

In tying the subclavian artery in the third division of its course, the blade of the knife ought never to be used after dividing the integuments, platysma myoides, and cervical fascia; for if this caution be not duly observed, instantaneous dissolution might be the result, either from a wound of the artery itself when taking a course as in the case just related, or from a division of the phrenic nerve, should it chance to be situated at the outer margin of the scalenus anticus muscle, our principal land-mark for laying hold of the artery when operating in this situation.

In securing arteries it cannot be too strongly impressed on our mind the necessity of trying what effect constricting the part included in the ligature has upon the pulsating tumor, when operating for aneurism, or what impression is made on the hæmorrhage in cases of wounded arteries; for the wrong vessel, and even nerves, have been tied by eminent surgeons for want of this precaution; and in operating upon the neck, where the vertebral artery, as in the above case, is larger than natural, superficially situated, and ascending parallel to the carotid as high as the

second cervical vertebra, although the latter is contained in a dense sheath, along with the internal jugular vein and pneumogastric nerve, the greatest caution is requisite lest the one be mistaken for the other, and the wrong vessel secured, and thus the sufferings and danger of the patient considerably augmented.

CLINICAL AND OTHER MEDICAL INSTRUCTION AT PARIS.

To the Editor of the Medical Gazette.

SIR,

IN your number for October 29, 1836, there is an account of the state of public instruction in France, which seems to call for a few remarks.

It is evident the writer received the information given him with no unjustifiable scepticism. We are told that the physicians and surgeons devote daily two hours in the wards of the sick, and afterwards retire to the operating theatre to deliver one hour's lecture on the most interesting cases in the wards.

Now, admitting that it was unnecessary to specify Sunday as in some degree an exception, is it seriously meant to be affirmed that the physicians and surgeons in general "devote daily," &c.? If this be really the case, will this intelligent English student on a future occasion inform us in a general way how many pupils attend the visit of each of these physicians and surgeons, and how many of them remain to the end of the lecture. On this subject I suspect that some one has been practising on his "*bonne foi*."

That the zeal of the French physicians and surgeons in giving clinical instruction is often very great, I willingly admit; but such unqualified assertions as the above are calculated rather to mislead than to enlighten those English students who may have thoughts of visiting Paris.

There is one point which correspondents from Paris seem to be shy of touching upon, and that is, the exclusion of pupils in general from the wards, except during the visit of the physicians and surgeons. This, of course, almost entirely prevents the possibility of a pupil's taking cases, and making

quiet observations for himself,—advantages so fully afforded in some of the London hospitals.

We are told that “les internes, in the absence of the surgeon, direct whatever treatment they think most proper;” that “if required, they may perform any operation in the absence of the surgeon; thus performing the duties of an assistant-surgeon in our English hospitals.” Now I cannot pretend, from recent observation, to assert that the internes have not such an extensive privilege of interfering in the treatment of the patients as is here attributed to them; but if they have, matters seem to me to be strangely altered of late years. In one point of view, indeed, this privilege may not be considered so very great, as the surgeons, by their daily visits, are not likely to leave much to be done in the intervals. However, I imagine that there is some exaggeration in this matter.

Five thousand bodies annually for dissection sound most magnificently to the ears of those accustomed to dissect in the English schools of anatomy; but if there is the same haste that there was some years ago among the “garçons,” in throwing away parts still in a very fit state for dissection, this magnificent supply will be found in actual value to be of a much more moderate character. It must not be forgotten that a large proportion of the subjects have previously undergone a thorough post-mortem examination in the hospitals*.

The gratuitous system of education as pursued in Paris has called forth the praises of many who have not, perhaps, duly considered the great waste of time that it indirectly occasions to the diligent student, by the crowding after popular lecturers, and the difficulty of getting a tolerable seat, unless by a long and wearisome waiting on the benches.

It operates injuriously also in this point of view, that the same individuals frequently attend courses on the same subjects, at different places, so that if in despair of getting near the lecturer, (on chemistry, for example) at L'Ecole de Médecine, you hope to be better placed at “La Sorbonne,” or elsewhere, you have a chance of finding yourself still thrown in the background, and that in

* Bodies altogether unopened form quite an exception, and are, I believe, generally obtained by special agreement with an interne or other official person.

a great measure by the very same individuals. If you attend the lectures of a Professor who is not popular, you are disturbed by the coming in and the going out of the pupils, to say nothing of their skipping along the benches. It is, I think, the late Monsr. Bertin, of whom the anecdote is related, that when pupils were coming in towards the end of his lecture, he used to say, “Messieurs, ma leçon commence à —” naming the hour, as if he supposed them to have mistaken it.

I understand that a professor who was formerly in the highest favor with the Parisian students, now addresses comparatively empty benches, until the crowd begins to flow in for the next lecture.—I remain, sir,

Your obedient servant,
EDWIN HARRISON.

Jan. 30, 1837.

MR. PHILLIPS'S REPLY

TO

MR. EVERITT'S ADDITIONAL REMARKS
ON THE
NEW PHARMACOPŒIA.

To the Editor of the Medical Gazette.

SIR,

I REGRET that I am compelled again to address you. I shall do so as briefly as possible.

Mr. Everitt observes that by “a curious coincidence” the same misprint of *three* for *two* occurs in my translation as in the original: surely Mr. Everitt does not expect that I should remember the quantities of ingredients used in every formula; or that when no doubt arose, I should on every occasion refer to original documents.

The statement is repeated by Mr. Everitt, that one measure and three quarters of water are more nearly required than two measures, to reduce one measure of the stronger solution of ammonia to the weaker one. This is not the case: when these fluids are mixed, neither expansion nor condensation occurs; and calculation coincides with experiment to prove, that when two measures of water are mixed with one measure of solution of ammonia of sp. gr. 0.882, three measures of solution of sp. gr. 0.960 are obtained.

It is remarked by Mr. Everitt that I have omitted the word “about,” used by him in directing the quantity of

water to be employed in a process: I admit the charge, but deny that the omission in any way affects the point at issue. He says that he did not intend to give the exact strength of the product: "I said, put 'about' (a little word omitted by Mr. Phillips) 30 parts of water." I shall not question Mr. Everett's intention, but I must maintain that his directions are precise for obtaining solution of ammonia of sp. gr. 0.960; the word about applying only to the quantity of water to be put into the receiver, and not to the whole quantity to be obtained; for Mr. E. says, "by the time that the 30 parts of water in the receiver bottle have increased to 35 parts, nearly all the ammonia will have passed over." There is no *about* as to the sp. gr. of the solution, nor any as to its quantity; and either by putting water into the receiver, or by distilling it with the ammonia, directions are distinctly given for obtaining 35 parts of solution of ammonia of sp. gr. 960, from ten parts of muriate of ammonia.

Permit me to add, that corrections of some errors occurring in the translation, may be had of Mr. Highley, the publisher.

I remain, sir,

Your obedient servant,

R. PHILLIPS.

Jan. 31, 1837.

INFLUENZA,

AS IT HAS PREVAILED IN THE HOUSE OF CORRECTION.

To the Editor of the Medical Gazette.

SIR,

SINCE my letter addressed to you on the 5th of November last, remarking upon the almost total absence of active or inflammatory disease in the metropolis, we have been visited by one of the most direful scourges, in the form of influenza, that has occurred within the memory of the oldest practitioner, and which in its consequences will be found to have been far more fatal than the cholera.

This disease, upon its first appearance, so much resembled inflammation of the bronchial passages, that the profession in many instances were induced to recommend bleeding. It is for the purpose of entering my protest against

this treatment that I have troubled you with this letter.

I shall confine myself to the treatment of the severe cases which have occurred in the House of Correction, and which have amounted, since the 27th of December to this period, to one hundred and five. Of these, ten have terminated fatally; the remainder either have recovered, or are in a fair way of doing so.

The urgent symptoms of fever, headache, and pains in the limbs, were soon relieved by the use of saline aperient effervescing medicine, which also quieted the nausea of the stomach. The oppression of the chest and difficulty of respiration were removed by the frequent applications of mild mustard poultices. In one instance only was I induced to bleed: no amelioration of the symptoms supervened. The blood shewed no appearance of inflammation, and a post-mortem examination convinced me that none existed. As soon as the febrile symptoms were subdued, even when the subsequent cough remained, I upon every occasion gave nutritious food, consisting of milk, broths, and most frequently the stimulants of wine and porter. This supporting plan I was induced to recommend from the fear of typhus fever following the great prostration of strength induced by the poison, and of which I had seen so many melancholy cases as the sequelæ of cholera.

The atmosphere still continues to be loaded with this fatal poison; it makes its attack upon the mucous lining of the bronchial passages, but does not deserve the appellation of bronchitis, a term which has been freely applied to it by the profession, very unscientifically I think, and likely to be productive of very erroneous treatment.

The rapidity with which some of the cases were carried off, where previous disease of the lungs existed, is hardly credible, and shews the concentrated character of the poison. I should very much like to be informed what the treatment has been in the large public institutions in London and the neighbourhood, and whether depletion has been employed to any extent.

I remain, sir,

Your obedient servant,

H. WAKEFIELD.

Lansdowne Place,
Feb. 2, 1837.

ANALYSES AND NOTICES OF BOOKS.

—
 "L'Auteur se tue à allonger ce que le lecteur se tue à abrégé."—D'ALEMBERT.
 —

Compendium of Lithotripsy; or an Account of Removal of the Stone from the Bladder without Incision; adapted for general comprehension, with a Series of Statistical Tables, and numerous Wood-cuts representing the most important Instruments and Improvements up to the present time. By HENRY BELINAYE, Esq. Surgeon Extraordinary to her Royal Highness the Duchess of Kent, &c. &c.

DURING the last ten years, we have taken frequent opportunities of laying before our readers an account of the progressive advances in that most important improvement of modern surgery—the art of removing calculi from the human bladder through the urethra. The progressive steps in the discovery have been made so rapidly as to require considerable activity to keep pace with them, and on some occasions we had scarcely described one invention ere another yet more important had been added to it. Some account of the present state of the art, and some description calculated to bring the subject within the grasp of all, had become a great desideratum. Inventors are often influenced by a natural affection for their progeny, which leads us to receive their testimony with some degree of reservation; and they themselves fully understanding all the details, sometimes take for granted an equal degree of familiarity with the subject on the part of their readers, which has led to their descriptions being occasionally less complete and elementary than might be desired. Now from these two causes of imperfection, lithotripsy has suffered, as regards its literature, and we think that a very important service has been rendered to this interesting branch of surgery by the author of the "Compendium" before us. Mr. Belinaye having none of the weaknesses of parentage to mislead his judgment, gives a description of the instruments which (to use a phrase more pithy than elegant) is "adapted to the meanest capacities," while his opinions regarding them, and his general estimate of the

operation, is evidently the result of minute observation and research. Here, therefore, we have the testimony of a competent and intelligent witness, free from any personal bias; and his evidence is of a nature to convince the most sceptical, not only of the abstract merits of the operation, but of the extraordinary mechanical genius and manual dexterity of Baron Heurteloup.

We strongly recommend the volume to those who are anxious to become acquainted with the progressive stages of discovery which have conducted to the present improved state of the art. For ourselves, we purpose merely to touch on one or two points, in order to show the manner in which our author has executed his task—not without the hope of inducing our readers to add the "Compendium" to their libraries.

Before we proceed to describe the instruments employed by Baron Heurteloup, it may be as well to make our readers acquainted with the bed (fig. 1) invented by him for the performance of his operations.

Three pieces of wood (A, B, C, fig. 1.) form the sides of the bed, and they are so joined as to form two right-angled triangles. They are united in front at the right angle, by a strong piece of wood (D D), and also by another of smaller size (E). The bed may be made to rest on the hypotenuse of the triangle by folding up the moveable portion (K K), which is done by unfastening the bar (M) which is fixed by a bolt at G. When this has been done, the bed rests upon B, which will now lie upon the ground. O, represents the mattress; S S, two pieces of wood, with slippers (U U), for the feet of the patient. In the space between D, P, D, is seen projecting a contrivance called the "support fixe," for giving steadiness to the instruments employed. It is also represented detached from the bed at 5, 3, 3.*

The next important step in the improvement of this operation seems to have been in the mode of grasping the stone, or rather of seizing it first, and then fixing it. To facilitate this, he invented an instrument having four branches instead of three, as had previously been the case, each admitting of being moved separately or simultane-

* For a full account of the "Lit Rectangla" and its numerous contrivances, we refer to the MEDICAL GAZETTE, vol. v. p. 206, et seq.

FIG. 1.

ously; so that when the stone had been caught, each branch could be individually adjusted, so as to render its hold more secure. The fourth branch had a

button-shaped extremity, which formed the termination or point of the instrument when shut, while, being open, it assisted in grasping the stone (see fig. 2.)

FIG. 2.

Sometimes the branches laid hold of the calculus in some awkward manner, not admitting of its proper adjustment by any of the ordinary means; and here we think one of the most ingenious and simple contrivances in the whole range

of improvement presents itself. It is not difficult to imagine a person attempting to grasp in one hand a ball, very large in proportion to the length of his fingers, and having originally laid hold of it in the dark, in some

awkward way, he finds it impossible to improve his grasp without first letting it go — impossible, that is, unless he brings his other hand to

his assistance. This is precisely what Baron Heurteloup does: he gives the instrument *another hand*, by introducing down through its centre a small three-

FIG 3.

branch pincers, which he calls the "pince servante," and which may be seen represented in the above engraving, fig. 3. By this contrivance the calculus is adjusted within the branches of the longer instrument, in the manner desired by the operator. The "pince" being withdrawn, he proceeds to act with the borer. But a better idea than any verbal description can convey will be gathered from the engraving fig. 2, which represents a large spherical calculus grasped by the four-branch instrument, and perforated by the drill, — the latter being in outline. When the calculus has thus been bored to a sufficient depth (a circumstance judged of by graduated marks upon the portion of the instrument which remains external), the drill is withdrawn, and an instrument called the excavator introduced in its place. The object of this contrivance

is to scoop out the interior of the stone, so as to reduce it to a mere shell: — here, too, however, we prefer appealing to the eye, fig. 4 exhibiting the action of the excavator when it has done its work effectually. Still there was the shell to get rid of; and the necessity of accomplishing this seems to have been the means of leading to a most important improvement in the principle of operating, — at least on stones of a certain size, — namely, that of breaking or crushing, instead of the slower process of rubbing or wearing them down. The instrument with four or even with three blades no longer served, and more simple and stronger mechanism became requisite. The desideratum was an instrument which might be closed upon the calculus if small, or its shell-like fragment, if it had required to be hollowed, — and farther, which might be

FIG. 4.

closed with considerable force. For this purpose he invented a kind of forceps, with two blades, so contrived that they could be drawn back into a sheath

with power sufficient to pulverize a calculus of ordinary consistence. This was the *brac coque*; and here it is (fig. 5); the blades of which, so formed as to retain

FIG. 5.

their hold, are jerked back by means of a click and spring into the tube through which they pass. This instrument,

however, is still better adapted for seizing a moderate-sized and long or oval stone; as seen in fig. 6.

FIG. 6.

But the manner of breaking the stone,—at least where it is of a certain size and consistence,—was destined to undergo another improvement, in which the simplicity of the process is still farther advanced. This consists of providing it with a hammer. This sounds rather formidable, to be sure, when we reflect that it is to be used in the human bladder, and that, too, when the organ has been rendered irritable by disease :

nevertheless, the problem has been solved. It consists in establishing a fixed point, against which the calculus is to be supported when it receives the blow,—a moveable blade, capable of striking it with sufficient force,—and lastly, keeping the whole clear of the sides of the bladder, that they may escape injury. Imagine fig. 4 in the centre of the bladder, distended by previous injection, and you have the “per-

FIG. 7.

cussor” of Baron Heurteloup. Like the *recto-curvilinear* sound, it consists of a straight and a curved portion. As the reader looks upon it (fig. 7), the extreme portion on the left is the fixed point,—the other the moveable blade or hammer, which, sliding in a straight stem (cut short in the figure), admits of being pulled back and driven in again upon the calculus with sufficient force to break it. At one time M. Heurteloup

thought of employing a screw, by which the plates should be gradually but very powerfully forced together, and the stone thus crushed ; but the tendency of the steel to bend, and other reasons, induced him to abandon this—we believe entirely. Still there was some inconvenience, from the fragments, when broken off, being, as it were, lost in the bladder. This induced M. Heurteloup to give the instrument a hollow or spoon shape, with

Fv

holes in it (fig. 8), so that when closed upon a fragment, and a few blows of the hammer are given "cautiously and judiciously," the superabundant portions are forced out through the apertures and at the edges of the instrument, which being then completely closed, is withdrawn with its cargo through the passage of the urethra, without risk or difficulty, as may be at once understood by glancing at the preceding figure.

Here we must close our account of this interesting volume. It is illustrated by nearly fifty wood-cuts, rendering the action of the instruments perfectly intelligible; and contains, in addition to the demonstrative part, many important considerations both theoretical and practical, together with numerous statistical tables connected with the subject of calculous disorders.

Reform der Heilkunst. (Reform of Medicine.) Von Dr. M. J. BLUFF. Leipzig, 1837. Schloss.

DR. BLUFF is a diligent observer of the actual state and progress of medicine. He gives us here the result of his observations for several years back, and without meddling with the question of external arrangements (which is of late usually implied by the term Medical Reform,) points out what he conceives to be the material alterations undergone by the medical art within the present century. His remarks are interesting, and though not often profound, are characterized in general by their aim at practical utility.

Das Auge von dem Standpunkte der Medicinal Polizei betrachtet. (The Eye, in reference to Medical Police.) Von Dr. J. H. BEGER. Heidelberg and Leipzig. 1836. Schloss.

A VERY curious essay on eye-quackery, eye-hospitals, the care which governments ought to bestow in preserving the eye-sight of their respective communities, eye-epidemics, &c.

Ueber die Anwendung der Ligatur bei Schlagaderwunden. (Application of the Ligature to Arteries.) Von Dr. K. J. BECK, Professor der Chirurgie, &c. Freiburg. 1836. Schloss.

WE have in this brief monograph the results of the experience of a distin-

guished operator, whose object it is to determine under what condition of wounded arteries the ligature is to be applied, in a remote or a neighbouring situation. The illustrative cases will be read with interest.

Die Lehre von den Augenkrankheiten. (Elementary Treatise on Diseases of the Eye.) Von Dr. J. C. JUENGKEN, Professor der Heilkunde in der Universität zu Berlin, &c. Berlin, 1836. Schloss.

THIS is a second and enlarged edition of Professor Jüngken's excellent textbook. It forms in its present shape one of the best works of reference; the literature is copious and well digested; and the tabular views of the diagnosis of inflammations of the eye are well calculated to convey much practical information.

MEDICAL GAZETTE.

Saturday, February 4, 1837.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."
CICERO.

QUARRELS OF QUACKERY.

THE *NEW* UNIVERSAL MEDICINE.

"WHEN rogues fall out," says the old proverb, "honest folk come by their own." We wish the simple honest folk who are so easily duped out of their *health* by designing knaves, could be equally fortunate; but they must be content if the quarrels of those rogues let them into a secret—how to keep "their own."

We observe, by the public prints, that a grand schism or defection has taken place among the Morisonian quacks. Salmon, the man who was convicted of manslaughter for having dosed to death Captain Mackenzie with "universal medicine," or, as he describes himself, "whose name has appeared so prominent in con-

nexion with Morison's pills," has split from his employers, and made some curious disclosures. He gives us an insight, for which we are much obliged to him, into the sort of traffic carried on by the "hygeian" party, and informs us of the kind of persons engaged in that trade. The most curious part, however, of this "plot discovered," consists in Salmon's confession of the badness of the pills which have for a long time been administered to the public. He says he frequently complained to the Morisons (for it seems there is a plurality of them) that the pills were not all right; but the hygeian presidents denied this, and would not admit that there was any imperfection: whereupon Salmon has appealed to the public, and exposes the alleged imperfections *seriatim*.

It was long ago shown in this journal that the pills in question, even were they harmless and fit to be exhibited, when carefully prepared, were likely to be rendered highly deleterious from the mode employed in manufacturing them on a large scale: one batch containing almost nothing but cream of tartar, for instance, while others belonging to the same lot were wholly composed of aloes or gamboge, yet all being professedly of the same degree of strength. It was thus, we argued, that the mischievous effects of the nostrum could readily be accounted for—some swallowing fifties together without damage, while others suffered death from the virulence of perhaps a smaller dose.

All this is fully confirmed by Salmon. Having stated first his suspicions, and then his detection of the spurious nature of the pills, he thus sums up the points to which he attributes the mischief:—1, to the slovenliness with which the drugs are prepared; 2, the carelessness in mixing and compounding them, each pill not possessing the due and requisite

quantity of each drug, and hence producing, as its natural consequence, a want of uniformity of operation; 3, the extremely *large* quantities required to be taken, owing to these defects [and the extremely *small* quantities, he should have added, which *ought* to have been taken in other cases, when the strong drugs fell to the lot of the unfortunate patient]; 4, the irregularity of size and shape of the pills, making it impossible to regulate properly the doses; 5, the extortionate price charged, and the short quantity given. Honest Salmon, no doubt, thinks this last item quite as bad as any in the list; and resolving to make pills of his own in future, promises to give better measure than the Morisons do, and for less money.

Of the badness of the old pills, he tells us he was quite convinced, and with the assistance of two other men, of the names of Bygrave and Hall, he is now resolved, he says, to offer for sale better pills than Morison's. This announcement, made in the public paper, is, of course, wormwood to the grand "hygeist," and forth comes a counter-statement from the latter, warning the public against the new firm, and telling us who Messrs. B. and H. are: one of them, it seems, having been Mr. Morison's footman, and the other a carpenter employed in the pill manufacture.

It is amusing to see how coolly these people set themselves to work in getting up their new purging establishment. Salmon explains the process adopted in the present instance. He was compunctious, we presume, about the mischievous properties of the old pills—those, namely, by which he committed manslaughter, and which led to his punishment—and "knowing that Messrs. Bygrave and Hall were principal assistants to the late Mr. Moat, and that they must necessarily be better acquainted with the compounding than either of

the two junior Mr. Morisons, who had no practical experience, and were not in *the firm* while Mr. Moat had the management," he got some medicine "brought out," as he calls it, by Messrs. B. and H., and "tested" (qu. by tasting, swallowing, &c.) its merits. The result is, that Messrs. Salmon, Bygrave, and Hall, have formed a coalition, and in the most patriotic manner offer to supply the public with the *only* genuine Morison's pills.

In other words, the matter may be thus stated:—Salmon, the tobacconist, and hitherto one of Morison's agents, having reason to know that he could make as good, if not better, pills than his employer, resolves to set up for himself; and having discovered the old original assistants—otherwise the footman and carpenter of "the firm,"—all three (*viz. the tobacconist, the carpenter, and the footman*) determine to manufacture, for the use of the public, pills more truly Morisonian than Morison's own. These pills are, of course, to cure *every* disease, and to be suited for every age, sex, and constitution: even "the babe of a day old may take them with perfect safety."

But the most remarkable circumstance yet remains to be noticed. These people have no difficulty in being regularly licensed to sell their new compound, and to tamper as much as they please with the health of the liege subjects. What a picture is this of the care bestowed on the public health by the government of the British Empire, and at such a time! It is but the other day, as we remember, that his Majesty was induced to grant a charter for the establishment of a new University, one of the avowed objects of which was to aid the cultivation of medical science, "in accordance with the spirit of this enlightened age,"—yet at this very time the royal sanction is granted to any quack who chooses to compound pills and offer them *for sale*. One hand is

thus held out for the encouragement of the medical art, while the other receives the tribute, and affords protection to the most barefaced quackery. How the Minister can reconcile this with the wisdom of an age so superior as he has described it, to that of the seventeenth century, is a problem which we fancy he might not, if pressed, find it very easy to solve. But to return to the licensed marauders.

It was our first impression, as it still is, on observing the mutiny in the Morisonian camp, that it would be beneficial for the public; the captain of the gang is no longer to have all the booty,—his lieutenant thinks he has just as good a right to be leader, and to be indulged with a larger share of the spoil; but this produces a deadly feud, and the parties "peach" and inform on each other.

The result of this, it were easy to foresee, in any well-ordered community; but it is rendered doubtful, when we recollect the facility with which "honest folk" among us are gulled by the most shameless impostors. If any thing could open the eyes of a British public to the gross humbug practised on them by these so-called "hygeists," it would be by the self-exposure committed by these fellows. Salmon, the tobacconist, the faithful, *tried*, and accredited agent of the Morisonian firm, has confessed the "imperfections" attaching to the pills as manufactured hitherto, and offers a better article instead; he forms a new connexion with a footman and a carpenter,—and lo, the public are forthwith informed that they are to be supplied with a new and *better* "universal medicine," and with "cleansing powders"—good weight and measure—at a "saving of twenty per cent.!"

We cannot but think that the hint is broad enough for the meanest capacity. Salmon's "new light" must illuminate a large portion of the community.

TRIAL OF MR. PENRUDDOCK.

AT page 715 will be found an account of the trial of Mr. Penruddock for an assault committed on certain members of the Court of Examiners at Apothecaries' Hall. The Worshipful Society proceeded against the prisoner for the capital offence, and had he been found guilty he could not have escaped with any punishment short of being transported as a felon. Now, however unjustifiable such an assault might be, still we apprehend that no dispassionate person can regard it as having been preconcerted, or as otherwise than the momentary ebullition of an impetuous temper, irritated by the disgrace of rejection; and viewing it in this light, we think it was both a hard and an injudicious measure to proceed against the prisoner on the capital charge. Had Mr. Penruddock been condemned he would immediately have become an object of sympathy, but this feeling can in no degree exist now that the capital indictment has been discharged, and he is merely to be prosecuted for the common assault.

DIVORCE OF THE BOROUGH HOSPITALS.

To the Editor of the Medical Gazette.

SIR,

YOUR last number contains a resolution purporting to proceed from the General Quarterly Court of Governors of St. Thomas's Hospital, held on Wednesday, the 18th instant.

I am aware that you are not likely to be deceived on such a subject; nevertheless, common justice to the governors of St. Thomas's compels me to suspend my judgment respecting the authenticity of this document,—first, because I find, by application at the Steward's Office of Guy's Hospital, that no copy of it has been transmitted to the persons whose interests are most directly affected by it; secondly, because some facts which, as an old student of Guy's Hospital, I have been able to ascertain, make me unwilling to impute such a resolution to any body of respectable gentlemen. In the year 1760 it was proposed that the pupils of each hospital should have the advantage of attending the operations in the other. In 1766 regulations were passed, and engagements entered into, for the purpose of enabling the pupils of each hospital to profit still more extensively by the practice of the other, and of securing the discipline and good order of the students; and by one of these regulations it was provided, that the pupils in each house should be subject to the control of the treasurer of that house.

In 1825, the Committee of Guy's Hospital remonstrated against some acts of the Committee of St. Thomas's Hospital which seemed to be a violation of the existing compact. The appeal was without effect; and the Committee of Guy's Hospital, after duly apprising the other party of their intention, built an anatomical theatre, and took other steps for the completion of their own school. None of these steps, however, in the least interfered with the privileges previously guaranteed to the students. They were confirmed by an express resolution of the St. Thomas's Committee, passed subsequently to the transactions in 1825; and every student, in each hospital, pays his money upon the faith that he possesses them.

These being the facts of the case, I submit to you, sir, that the Court of St. Thomas's Hospital cannot have passed the resolution which you have printed;—they cannot have taken advantage of a transaction respecting which a law-suit is still pending, for the purpose of doing injustice to a large body of students who were in no wise concerned in the disturbance complained of;—they cannot have committed the gross prevarication of saying that they were not consulted about the measures adopted by the Guy's Committee, in 1825, which they know were the result of a long previous negotiation;—they cannot have said that the union between the schools was dissolved in 1825, when it has existed for all purposes in which the public and pupils are interested till the present time.

With these doubts respecting the authenticity of the paper in question, I am, sir,

Your obedient servant,
A PUPIL OF THE SURGICAL SCHOOLS OF
GUY'S AND ST. THOMAS'S HOSPITAL.

Guy's Hospital,
Jan. 26, 1837.

[Sceptical as our correspondent may be, the document we published was authentic.—ED. GAZ.]

CENTRAL CRIMINAL COURT—

WEDNESDAY.

by Mr. Justice WILLIAMS and Mr. Justice COLERIDGE.)

LES WADHAM WYNDHAM PENRUDDOCK, aged 22, described as a surgeon, capitally indicted for feloniously killing Thomas Hardy, with intent to do some grievous bodily harm.

ADOLPHUS (with whom was Mr. INGHAM) stated the case for the prosecution.

detailing the facts of the case, as found in evidence, the learned counsel said that he felt bound to say that the prisoner, a gentleman, the prisoner at the bar, of a highly-respectable family, and belonging to a most honourable profession. The tutor was Mr. Thomas Hardy, one of the examiners at Apothecaries' Hall. On the day the prisoner committed the offence, he was a candidate for a medical certificate necessary to qualify him at Apothecaries' Hall. It appeared to the examiners that the young gentleman was acquainted with surgery, which he studied with credit to himself; but the examiners were of opinion that he was deficient in his knowledge of pharmacy, and the certificate he applied for was refused. The prisoner then, in a morose state of excitement, inflicted a blow with an instrument, strangely called a "bone preserver," and which would be presented to the jury—a blow that endangered the life of Mr. Hardy.

Mr. Thomas Hardy examined.—I am a surgeon retired from practice, and reside at North. I am one of the examiners at Apothecaries' Hall. I was there on the day in question and saw the prisoner, who was one of the candidates for a certificate. I observed something very peculiar in his manner; he appeared to be labouring under much excitement. He hastily took up a box of sarsaparilla, which he bit and threw down. I was in the room where the certificate sought for by the prisoner was disallowed. I saw the prisoner strike at Dr. Merriman, but I saw no weapon in his hand. I saw an instrument afterwards which I was told had been taken from the prisoner. During the examination I was near the prisoner he looked at me, and said, "You are one of those who were hard with me." Immediately after that I received a violent blow on the head, but I am unable to state whether the blow was struck with an instrument or not. I became faint and was unconscious in consequence of loss of blood.

By Mr. PHILLIPS, for the prisoner.—There appeared to be a great degree of excitement about the prisoner. He spoke deridingly of the examiners. He said he would not be degraded by them in the eyes of his family; he would die, or he would swing first.

Mr. Randall, surgeon, confirmed the greater part of the above testimony, and proceeded to state that while the prisoner was under the examination of Mr. Este, he was asked the use of cubebs. The prisoner in reply said, "I know it very well." A person is not fit for an apothecary who does not know the use of it; but he did not seem to know the purpose for which it should be applied. Mr. Este said, "Don't you know that it is used for a specific discharge?" The prisoner replied, "Oh, yes." Knowing that he had been at St. George's Hospital, Mr. Este asked him if he had not seen it used there? He again said, "Oh yes." He was again asked as to its use, but he made no reply. He not answering, I said to the prisoner, "The gentleman means in what form and in what proportion is it to be used?" The prisoner turned round to me, and said, "how the devil can I answer questions if you are all *badgering* me in this kind of way?" My conduct to him at the time was mild and friendly, and not tending to irritate. After other questions were put, the prisoner attempted to excuse himself by saying, "I never could answer questions, even when at school, although I knew as well as any other boy." He was told that the answer was required, in order to show that his knowledge qualified him for practice. The examiners never wish to hurt the feelings of any candidate, but they have a very important public duty to perform, and he told the prisoner so. The prisoner replied hastily, "Sir, you have behaved very gentlemanly, and so has that gentleman (pointing to Mr. Este). The prisoner then said, "Pray examine me in anatomy; I understand that, for I have lived in a dead-house." The Court of Examiners is competent to examine in the science of anatomy, but it is the usual custom first to examine as to *materia medica*. Mr. Randall refused to examine the prisoner in anatomy, observing at the time that that branch of inquiry came more properly under the cognizance of the College of Surgeons. He (Mr. R.) said, if the first anatomist in the world was ignorant of *materia medica* and pharmacy, he would not be a fit person to receive a certificate of practice. It was then suggested that a few simple questions should be put to the prisoner, which not being promptly answered, Mr. Este, the chief examiner, observed that he could

not, consistently with his duty, consent to grant the required certificate. The prisoner then said to the examiners, "Your certificate is of no advantage to me in a pecuniary point of view, as I am going abroad and have good resources; but do you think I am going to be disgraced in the eyes of my family by such a set as you are? No, I'll be d—d if I will, I'd die first—I'd swing first!" The prisoner then arose from his chair, raised his right arm above his head, and aimed a blow at Mr. Hardy. I did not see anything in his hand, but afterwards I saw an instrument which is called a life-preserver, which was said in the prisoner's hearing to have been taken from him.

The witness was cross-examined at considerable length, but nothing was elicited to shake his examination in chief.

Mr. Tegart.—I am an apothecary, and live in Pall-mall, and am one of the examiners at Apothecaries' Hall. I was on duty there on the day named in the indictment. I heard the questions put by Mr. Este and others to the prisoner, who did not answer them.

Mr. Bacot stated that he was present when Mr. Hardy was struck. The blow appeared to have been struck with a blunt instrument. That now produced would inflict such a contusion. Has understood it to be called a life-preserver.

Mr. Justice WILLIAMS said he had seen such instruments exposed for sale in shop-windows; hence he feared they were very common.

The witness continued—There was a good deal of blood flowed from the wound, and Mr. Hardy was attended daily by him for about a fortnight. The wound was not in its nature dangerous in the first instance, but serious consequences might have arisen, and loss of life, had inflammation ensued.

By Mr. PHILLIPS.—Medical students were in the habit of being out at all hours of the night, and might require an instrument for self-defence.

Mr. PHILLIPS replied at great length in an energetic speech. The learned counsel argued against the possibility of the weapon which he then held in his hand—used by a powerful young man—having caused the wound. A child of twelve years of age would have caused, with such an instrument, a greater injury. But with a powerful arm, bones must have been fractured by a blow from such an instrument. Mr. Phillips contended that the blow was inflicted with the naked fist, used in a moment of passion.

Mr. Justice WILLIAMS.—Perhaps you had better have the surgeon recalled.

Mr. PHILLIPS.—Then, my lord, I wish he may be called now.

Mr. Bacot, recalled, gave the same description of the wound as he had in his testimony in chief, stating his opinion to be that it could not have been produced by the knuckles of a man: it was just such a wound as he had seen produced hundreds of times by a spent ball.

Mr. PHILLIPS resumed.—He was not sorry Mr. Bacot had been recalled, for it proved that he was not fully aware how the wound had been inflicted. He said it was like a gun-shot wound. Why, had not the jury, in street broils and fights, seen wounds exactly similar to the one described? In making the observation, he did not wish to disparage the professional reputation of Mr. Bacot, who was eminent for his long experience. The learned counsel appealed to the feelings of the jury to restore the young gentleman at the bar to the highly respectable family to which he belonged, and to acquit him of the grave charge made against him, and which he and his family so severely suffered under. That the prisoner had been guilty of a most imprudent and desperate assault, he (Mr. P.) would not deny or palliate, but he called upon the jury for an acquittal on the indictment before them. If their verdict should be favourable, yet would the unfortunate young gentleman be removed back to his dungeon to await another indictment, which, no doubt, would be preferred against him. The learned counsel concluded by observing, that there was no proof of malice as to the prisoner having the life-preserver in his possession; it was necessary even in the well-guarded metropolis, for medical students, who were out late at night, attending lectures, to have defensive weapons for their protection.

Mr. BODKIN called Dr. Seymour and several gentlemen in the medical profession, who gave the prisoner an excellent character for humanity and general good conduct.

Mr. Justice WILLIAMS summed up at length, with much perspicuity, stating the law, recapitulating the evidence, and commenting thereon.

The jury retired to consider their verdict, and on their return pronounced a verdict of *Not Guilty*.

The Court was moved to detain the prisoner to give time for an indictment of assault to be preferred against him.

The JUDGES assented, and ordered the prisoner to enter into his own recognisance of 200*l.*, and two sureties of 100*l.* each.

OPERATION OF THE ANATOMY ACT IN DUBLIN.

To the Editor of the Medical Gazette.

SIR,

ABOUT two years since a statement of the Dublin teachers of anatomy was published approving of the Anatomy Bill. It must gratify the author of that law to find that longer experience confirms their good opinion. It is effecting a slow but certain revolution in favour of the whole profession, and removing the odium which the outrages of resurrection-men attached to medical students. I inclose the resolutions of the teachers of the eight schools of Dublin, at their first meeting this year, and remain, sir,

Your obedient servant,
ARTHUR HASSALL.

Harcourt Place, Dublin,
Jan. 1837.

We the undersigned teachers of anatomy in the city of Dublin, consider ourselves called upon to state for the information of his Majesty's government that the most satisfactory results continue to follow the enactment of the Anatomy Bill. The supply of bodies is amply sufficient for the purposes of instruction; the practice of exhumation is rendered unnecessary, and if perpetrated at all, is only resorted to by persons seeking for teeth for the use of dentists.

For these most satisfactory consequences we consider ourselves indebted principally to the judicious arrangements, official firmness, and praiseworthy impartiality, of Sir James Murray, and we here venture to express a hope that the Chief Secretary will have the goodness to continue that support and countenance to his exertions which the government has hitherto been pleased to afford.

Arthur Jacob, Professor of Anatomy,
Royal College of Surgeons.

Robert Harrison, Professor of Anatomy,
Royal College of Surgeons.

John Nolan, Demonstrator of Anatomy,
University of Dublin.

H. Carlisle, A.B. Demonstrator of Anatomy,
University of Dublin.

William Hargrave, M.B. Lecturer on Anatomy and Surgery, Digges-
street.

John Hart, M.D. Lecturer on Anatomy, &c. Park-street.

Andrew Ellis, Lecturer on Surgery,
Peter-street.

G. T. Hayden, Lecturer on Anatomy and Surgery, Peter-street.

John H. Power, Lecturer on Anatomy and Physiology, Richmond Hospital.

John Denham, Lecturer on Anatomy, Marlborough-street.

Dublin, Jan. 1837.

ANOMALOUS CONDITION OF AS- SISTANT SURGEONS IN THE NAVY.

To the Editor of the Medical Gazette.

SIR,

MAY I beg the favour of your inserting in your journal the inclosed letter to Sir William Burnett, which, by calling his attention publicly to the lamentable condition of the naval assistant surgeon, may lead to an investigation, and probably some improvement.

I remain, sir,
Your obedient servant,
B. M. W.

Clifton, January 1837.

SIR,—Considering the high and influential station you hold in the navy, being placed at the head of one of its most important offices, I conceive you to be the proper person to whom we must apply for the removal of certain evils existing in the department over which you preside. I cannot for a moment doubt that you feel due interest in the welfare of every officer, and that you will spare no efforts to render their condition equal to their expectations. The curriculum of studies issued of late years, and which demands from the candidate for the naval service more than any other institution in the kingdom, reflects the greatest credit upon those with whom it originated; and I refer to it with the more pride, as showing that in you, sir, we have a friend who, guided by the dictates of benevolence, has commenced an improvement calculated to be as beneficial to the medical officers themselves as to the naval service in general. But promising as it bids to be, and bright as the future may be expected from its salutary influence, I much fear the grand tendency of this improvement will be curtailed, or altogether frustrated, by the evils which exist in a quarter where its objects should be most promoted. In the endeavour to increase the extent of medical knowledge in the

navy, proper care seems not to have been taken to cherish its strength in the very cradle of its existence: the young candidate is informed that he is expected to be prepared in such and such branches of science; he observes that the amount of professional knowledge required is actually more than that demanded at the College of Surgeons, London, or the University of Edinburgh; and he very naturally concludes, that, after passing his examination at such a board, he will be expected to retain and increase it, and that every facility will be afforded him to do so; and few can tell how great his disappointment on finding the case otherwise. There can be no doubt that this period of his life, that which immediately succeeds his entrance into the navy, is the most important to him; for as this season is employed or neglected, he will become either a credit to himself and his profession, or an annoyance to both.

It has always been a subject of much regret to me, that the assistant-surgeon should be stationed with the midshipmen; their habits being necessarily so different to his own as to preclude the hope of all serious study. But independent of this, his accommodations are by no means what they should be. It is no apology to say that all who enter the navy must commence at the bottom and climb to the top, for true and justifiable as the observation is, yet the assistant-surgeon belongs to his own department; and though all naval officers collectively come under the same regulations, nevertheless each department has its peculiar exemptions. The medical man neither enters as a midshipman nor expects the treatment of one; but he enters as the member of an honourable profession, and claims that protection and respect which I trust it will ever deserve. If we followed the example set us in the army, the assistant-surgeon would at once be stationed in the ward-room; it is nothing more than a compliment he merits, and one which at least, out of decency, should be paid him. I think, sir, you must allow that this arrangement ought to have been made long ago, but now it becomes imperative, if, at least, the improvements which you have so wisely commenced are to effect any ultimate good; and I may here observe—and I do so with all respect—that whatever increase you make in the acquirements of candidates, and leave this evil unreclaimed, it will only be heaping sorrows on his head, and, instead of improving his condition, will increase the amount of his misery. Indeed, the idea of expecting better educated men than ordinary to enter this service, without any

security for their future comfort, or the prosecution of their studies, seems too unreasonable to require comment.

It is for the remedy of this grievance that I have taken the liberty of addressing you, but I am sure you must see the necessity of a change, and the disastrous consequences which attend the present state of things, far better than I am able to point out.—I have the honour to be,

Your obedient servant,

B. M. W.

To Sir Wm. Burnett, M.D. &c. &c.
Royal Navy.

MEDICO-BOTANICAL SOCIETY,

On the Corowatti.

A PAPER, by Dr. John Hancock, on the *Corowatti* of British Guiana, and its use by the natives, was read. This plant belongs to the natural order *Drymyrhaceae* of Decandolle, a large and very elegant herbaceous perennial growing in sandy soils, on the sides of hills and ravines. It is a species of *Alpinia*; but whether it be new, or the *A. exaltata* of Meyer, is uncertain; for great confusion prevails throughout this natural family.

The plant in question is bitterish, piquant, and sub-acrid: both the root, leaves, and fruit, are held in high esteem by the natives, for their medicinal properties, being with them a sort of panacea, as is the ginseng amongst the Chinese and Tartars, although the fruit is chiefly valued on account of its fine purple dye. A strong infusion of the bruised root, which is diaphoretic, diuretic, and in large doses emetic, is used in dropsies, rheumatism, dysentery, fevers, colic, pains, hooping cough, &c. In the latter disease, a convincing proof was adduced of its great efficacy in a large family, all of whom were speedily cured by taking an infusion and syrup of the root. The residence of this family was far distant from the settlement, in the woods of Pomeroon, and having no communication whatever with any one infected; this was regarded by the author as one evidence of the epidemic origin of the disease (hooping cough); or that it is propagated by a peculiar condition of the air, rather than by contagion. In dropsy, the natives both take the root internally,

cover the parts affected with the vesicles, and not unfrequently they envelope the whole body with them, which brings on a profuse perspiration, which often frees them quite free from their complaint. In cases of poisoned wounds, the fixed root is laid on the part, and its action taken internally. Dr. Hancock remarked on our remedial practice in enteric and whooping cough, and urged it as a matter of the utmost importance, to cure perspiration, especially by the use of external stimulants, the vapour bath, diaphoretic ptisans, saline aperients, topical or general bleeding, as indicated by symptoms*. Such means, without incommencing the stomach, rouse the morbid elements into action, and by exciting the exterior surface, incline the fluids thereto, and thus by revulsion relieve internal congestions, with more certainty than by any other method, and often, indeed, when internal remedies alone would be utterly useless.

The paper concluded by remarking on the propriety of attending to the indigenous remedies of the country, the importance of which had been illustrated by the noted president, Earl Stanhope, in his lectures before the Society; and the audience could not doubt that much advantage might be gained from the external application of large leaves of certain plants of this country, in a similar manner to those mentioned above, as, for instance, the *clidonium majus*, *Rumex*, *Arum maculatum*, &c., in aid of internal medications.

Analysis of Bitter Almonds.

Dr. Everitt, the Professor of Chemistry, read some curious facts at which the modern chemists have lately arrived, relating to the analysis of bitter almonds. A substance called amygdaline was obtained by macerating the bruised seeds in alcohol or æther; but it was proved that hydrocyanic acid, or essential oil, was contained in them; and that these principles are not *educts*, but mere *products*, freed by water or by mastication: that zotic acid is formed in the volatile oil in its union with oxygen, and the bitter principle is developed only by attracting to or nitrogen.

The same practice he has found to be most

ROYAL INSTITUTION.

Friday, Jan. 27, 1837.

Processes of Embossing.

MR. BRANDE this evening gave an interesting lecture on the various processes at present employed in the embossing of paper, cloth, leather, &c. Many beautiful specimens were exhibited, and some were actually produced in presence of the audience, by expert workmen who were in attendance. The ingenious methods of making splendid metallic papers were demonstrated, and the whole art of manufacturing gold, silver, and jewels, for theatrical use, was laid open. To Messrs. De la Rue the lecturer acknowledged his obligations, for the opportunities of illustration thus afforded him from their magnificent establishment.

PRESENTATION OF PLATE TO
SIR C. BELL.

A LETTER has been received by a member of the Committee of Management, from Sir Charles Bell, dated Edinburgh, December 31, 1836, part of which we have been requested to publish:—

"My dear sir,—I have to-day received the most gratifying proof of esteem from my friends in London. The inscription on the vase touches me sensibly, and expresses all that I have coveted during my toilsome life in the metropolis.

"Convey to the subscribers my lively sense of this mark of their remembrance. You cannot use words sufficient to express the importance I attach to this new proof of their esteem.—I am, my dear sir,

"With all sincerity, yours,

(Signed) "CHARLES BELL.

"To Dr. Loeck."

UNIVERSITY COLLEGE AND
NORTH LONDON HOSPITAL.

DR. A. T. THOMSON.

[THE following communication reached

Friday. We have inserted it at great inconvenience. Of the circumstances of the charge against Dr. Thomson we repeat that we know nothing; we merely published the authenticated statement of a pupil of the North London Hospital.—**ED. GAZ.]**

We, the undersigned students at the London University, having observed an article in the last number of the **MEDICAL GAZETTE**, which attempts to impute a want of attention on the part of our esteemed professor, Dr. A. T. Thomson, to the duties of his station, feel ourselves called upon to express, most distinctly, our firm conviction of the utter untruth of such imputation, and thankfully to acknowledge the advantages we have derived from the constant and unwearying attention bestowed by the Professor, in promoting the instruction of the students as well at the hospital as in the classroom;—an instruction enforced not less by the talents of the Doctor than by the urbane and gentlemanly manner in which that instruction is at all times conveyed.

[Here follow 112 signatures.]

LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE XX.

INFANTICIDE. *Causes of its frequency in civilized communities—Among ancient nations—Prevalence in the East—In the western world; but no where among savage tribes. Legal positions and distinctions respecting child murder—Born alive; various decisions as to the meaning of the phrase—Law of concealment of the birth—Objects of medico-legal inquiry: 1. Was the infant born alive?—Obvious signs of survival of birth—Certain sign of still birth—Question of respiration—External and internal appearances. Proofs from the state of the lungs—Their colour, volume, consistence, absolute weight, and specific gravity. Ploucquet's static lung-test—Its value, as modified by subsequent and recent observers.*

WE now proceed to the consideration of a subject which is usually held to be as intricate as it is important in medico-legal science—namely, that of

INFANTICIDE.

Infanticide, or child-murder, implying in its ordinary acceptation the wilful and violent death of the new-born child, is a crime which, from its heinousness, its frequency, and the difficulty that often attends its proofs, demands the most earnest attention of the medical jurist.

Causes of Infanticide in civilized communities.—It is worth remarking, that infanticide has been observed to be most frequent in states or communities which are said to

enjoy the blessings of civilization; and the causes which lead to it are perhaps not difficult to be assigned. "To parents," says Professor Beckmann, "who are just able by incessant labour to procure those things indispensably necessary to support life, the birth of every child increases the fear of starving, or of being reduced to beggary. Those who have secured to them a scanty subsistence, but who live in servitude, wish to the new-born child a speedy dissolution, before it can know that it has had the misfortune of being brought into the world, in order that they may not bequeath to it their poverty. A young female, who has acquired by education the most delicate sense of honour and shame, finds herself, on the birth of an illegitimate child, exposed at once to the utmost disgrace and contempt. Her misfortune, though viewed with an eye of pity by the compassionate, excites the hatred of the greater part of her relations and friends, by whom she was before loved and respected, and who endeavoured to render her happy; and often amidst the most poignant feelings, and an agitation bordering on madness, she sees no other means of saving her honour than the total concealment of her error by destroying the child; a resolution which, notwithstanding the vigilance of the laws, is too often attended with success. A young woman who at this moment finds herself suddenly despised and neglected by her admirer, who gained her affections by the most powerful of all means, love and confidence, and obtained from her what she cannot recover, is often induced, in a fit of despair, to vent her fury on the consequences of her seduction—the child of her seducer."

Its frequency in ancient times.—Previous to the Christian æra, and until the morals of mankind began to be improved under the influence of Christianity, the practice of infanticide prevailed to a monstrous extent. Among the Greeks it was not only tolerated, but in some states enforced. The Romans,

however, seem to have surpassed all other nations in this kind of cruelty ; nor was it till a comparatively late period of the empire that the vice was eradicated by the terrors of capital punishment. In the Justinian code, the crime of murder was imputed to the father who strangled, starved, or abandoned his new-born infant, or who exposed him in a public place, "to find that mercy which he himself had denied." "But," as Gibbon says, "if the father could subdue his own feelings, he might escape, though not the censure, at least the chastisement, of the laws; and the Roman empire was stained with the blood of infants, till such murders were included by Valentinian and his colleagues in the letter and spirit of the Cornelian law."

Tacitus mentions it as a circumstance deviating from the Roman manners, that the old Germans considered child-murder as a crime; and where he speaks of the peculiarities of the Jews, he does not fail to relate the same thing of them,—although, by the way, it is curious that there is no law in the Pentateuch whereby child-murder is prohibited.

Prevalence in the East.—In certain Eastern countries infanticide is still very prevalent. In Hindostan, for example, parents sacrifice their children to the Ganges, or to any power whom they wish to propitiate; but the practice has been much restrained by the interference of the English government, particularly under the auspices of the Marquis Wellesley. There is, however, a race of Rajpoots in Western India, who are said to have been in the habit of immolating *all* their female children; nor have the benevolent exertions of the English residents and missionaries in any considerable degree succeeded in suppressing the cruelty. The motive is supposed to be a religious or superstitious one. But even among the better and more enlightened classes of Hindoos, and where the parents have no poverty to plead, the practice of destroying newly-born children, particularly females, prevails to a great extent: it is persevered in apparently through a calculating spirit of domestic policy; and the unfeeling manner in which the death-sentence is pronounced by the father, when he is informed of the birth of a daughter, shows at once the familiarity of the custom and the levity with which it is regarded. "Give it milk!" is the fatal mandate; whereupon the child is drowned in a pail of milk, or, as others report, a milk vessel is forced over the infant's head, so as to produce suffocation. Other methods of effecting the child's death are mentioned by Buchanan, in his *Christian Researches*. As soon as it is found that the infant is a female, a piece of opium is

put into its mouth; or the umbilical cord is drawn over its face, which, by preventing respiration, destroys it.

The Chinese also are notorious for the numbers of children, chiefly female, which they destroy, or expose. In Peking alone, it is said that several thousands annually are thus got rid of.

In Ceylon it is rare to find more than one daughter in any family, and the last general census of the island in 1821, shows that the number of males exceeds that of females by 20,000. The difficulty of marrying their daughters, and giving them marriage portions, is generally alleged as an excuse for destroying them.

In the western world.—Among the old American nations—the Peruvians and Mexicans, for example, the sacrificing of children is said to have been a common custom; and travellers record the names of several tribes belonging to the southern continent, such as the Abipones and Araucanians, who were in the habit of murdering their infants. But, as Dr. John Beck observes, "to the honour of our North American Indians, it deserves to be mentioned that they are not known to be guilty of this horrid crime. Mr. Heckewelder, in his interesting account of the Indians who inhabited Pennsylvania and the neighbouring states, says, 'I have never heard of any nation or tribe of Indians who destroyed their children, when distorted or deformed, whether they were born so or come to be so afterwards.'"

This, however, is only in accordance with the observation which has already been made—that it is the artificial restraints of society, and the difficulties apprehended in rearing offspring according to the usages of civilized communities, that lead to the perversion of one of the most natural of our instincts: for in the savage state, parents require no more for themselves and their children than they can easily obtain, and are thus exempt from those influences which would, in other circumstances, interfere with the kindest feelings of nature.

Legal positions and distinctions respecting child murder.—The term child-murder has sometimes been applied in an extended sense to fatal injuries inflicted by the mother, or other persons, on the foetus *in utero*. It appears to amount, as I mentioned in a former lecture, to homicide, or manslaughter at least, if, on the subsequent birth of the child, those injuries prove to be of such a nature as to cause its death. According to Lord Coke, if the child be born alive, and afterwards die in consequence of injuries wilfully inflicted on it while in the womb, it is murder. In a case where a midwife injured a

child's head before it was born, she was found guilty of manslaughter; the child having been born alive, but having died soon after of the injury.

But the more ordinary charge of infanticide occurs in cases where the mother is supposed to be guilty of the murder of her child after it is born.

It has been decided, that in order to substantiate this charge, "the whole body of the child must have been brought into the world prior to the extinction of life." When this is left doubtful, the mother will most probably be acquitted.

It has also been decided, that the child cannot be considered as born alive until it has had "an independent circulation." On which decision a question might arise, whether, if the umbilical cord were not severed, there could be infanticide? And hence also, though it should be proved that the child breathed, that fact is not sufficient to constitute the killing child-murder; for the child might have breathed before it was born (wholly), or had an independent circulation.

The fact of respiration is commonly held to be proof of live birth. But with respect to the evidence of breathing, it has sometimes been considered not sufficient to prove that a child has breathed, when circumstances leave it doubtful whether the breathing was not merely during the birth, and before the establishment of an independent circulation.

According to the decision in an important case, *Rex v. Poulten*, (5 Car. and Payne, 329), "Being born must mean that the whole body is brought into the world, and it is not sufficient that the child respire in the progress of birth." Mere proof of having breathed is not enough: for, according to the evidence in this case, First, it may happen that the child is born as far as the head is concerned, and breathes, but death takes place before delivery is complete; secondly, death might have occurred when the child was partly born, if no medical man was present to assist delivery; and thirdly, it may be impossible to say when the child respired; the breathing may have occurred during parturition.

On the other hand, infanticide may be committed after birth, though before the child has breathed. The circumstance of its being proved that a child has never breathed is not conclusive that the mother has not been guilty of infanticide.

In the trial *Rex v. Brain* (6 Carrington and Payne, 349) it was decided that proof of breathing was not essential, the child having been wholly born, and alive; but the jury must be satisfied that the child was wholly born. Two surgeons proved that the child had never breathed; but it

was urged that many children are born alive, yet do not breathe for some time after birth.

However, upon all trials for infanticide by a mother, the question whether a child has breathed or not is a material topic of inquiry. If it has not breathed, acquittal is almost sure to follow; it is, therefore, very important, in order to support a prosecution, to establish the fact that the child has breathed; and the medical witnesses both for the prosecution and defence ought to be able to speak very minutely as to the breathing.

Generally the point of discussion is, whether a live child, (that is, as usually understood in criminal cases, one that has breathed) has been killed or not. But sometimes it is reduced to this, whether supposing a live child has been killed, it has been killed by pure accident.

I believe there is no case in the annals of English jurisprudence, where, upon a trial for infanticide, the question has turned on the point, whether the child having been killed, the death was caused by the gross negligence of the mother; nor is there an instance that I am aware of, where the mother has, through any omission, been found guilty of manslaughter. The charge has either been murder, or concealment, or nothing.

The law of concealment of the birth is so closely connected with our present subject, that it may without impropriety be introduced here. By the 14th section of the *Lansdowne Act*, (9 Geo. IV., c. 81) "If any woman tried for the murder of her child shall be acquitted thereof, it shall be lawful for the jury by whose verdict she shall be acquitted, to find, in case it shall so appear in evidence, that she was delivered of a child, and that she did by secret burying, or otherwise disposing of the dead body of such child, endeavour to conceal the birth thereof, and therefore the court may pass such sentence as if she had been convicted upon an indictment for the concealment of the birth."

It is added, that when a prisoner is tried for the concealment, "it shall not be necessary to prove whether the child died before, at, or after the birth." Hence, on an indictment for this crime, it must appear that the mother was delivered of a child, and that the child was dead; though whether it died *before*, *at*, or *after* the birth, need not be proved.

The special mention here of proof as to *when* the child died, seems distinctly to imply that such proof is essential on the capital charge of infanticide.

One other circumstance connected with indictments for concealment of the birth is worth noticing. No costs are allowable on such trials. In consequence of which,

as Sir Gregory Lewin observes, in his concise and excellent Northern Circuit Reports, "it is sometimes the practice to indict the party for murder, though it is well known the evidence will not support the charge; and by this stratagem the prosecutor contrives to get the usual costs allowed for a felony prosecution, notwithstanding the jury negative the murder, and find only the concealment." But the impropriety and cruelty of this mode of proceeding have been severely censured from the bench, and the costs refused.

Objects of medico-legal inquiry.—From the preceding summary of the legal distinctions respecting infanticide, we may gather that the usual defence set up in all such cases is, that the child did not live—that it was born dead. And this, in fact, is the general plea advanced for the prisoner; the *onus probandi* of live birth resting with the prosecution. Unless it can be proved that the child actually survived birth, and died in consequence of certain violence inflicted on it, the charge of murder cannot be supported.

Whoever attempts to reconcile the decisions on the law books as to the amount of proof requisite in cases of infanticide, will find himself not a little bewildered; the evidence of live birth itself, or what is to be considered as such, is far from being precisely determined; and the bench and bar have here, as in many other points of forensic medicine, a wide discretion secured to them.

It may be stated, however, in general, that the main objects of inquiry in cases of infanticide are twofold:—1. Whether or not the infant was born alive; and 2. Whether death was occasioned by natural causes or the infliction of violence.

1. *Was the Infant born alive?*

Following this simple arrangement of the subject, we shall proceed to consider, in the first place, the proofs of live and still birth in criminal cases; or, to describe our purpose more in accordance with the spirit, if not the letter, of the law, we shall inquire what grounds there may be for concluding that the child died *before*, *at*, or *after* delivery.

The appearances presented by the body afford us the best means of forming a just conclusion.

Question of maturity.—One of the first points that deserve our notice is the age of the fetus in respect to intra-uterine life. Is it a mature infant or immature? For in proportion to its immaturity may we presume that there was the less chance of its being born alive.

I have already described the characters derived both from the external and internal inspection of the fetus,

by which we can arrive at certain conclusions respecting its age from conception.

Sure signs of having survived birth.—But it may happen that there shall be certain appearances observable which shall decide at once the question of survival of birth. For example, certain conditions of the umbilical cord, and of the cuticle. These have been noticed in a former lecture, in reference to the age of the new-born child; but it may not be improper to repeat the description of them here, however briefly.

Should it appear that the umbilical cord has sloughed off,—not from putrefaction,—not only was the child born alive, but it must have lived four or five days. If the cord has not only sloughed off, but the navel has become cicatrized, the infant cannot exactly be considered as *new-born*, for it must have lived about ten days. As to the cuticle, the process of *desquamation* begins to take place when the child is a day old. If, then, desquamation of the cuticle (which must not be confounded with peeling off of the skin from putridity) be observed, the infant certainly came into the world alive, and continued to live above a day at least. In either of these cases, the labour of the medical jurist is materially abridged; he need not apply the tests, hereafter to be mentioned, for live or still birth, but merely confine himself to the question, whether the death of the infant was natural or owing to violence.

Another obvious case of the same kind would be, when, upon examining the stomach, it should prove to contain milk or other food partially digested. Such cases have happened: the body of a child has been found, evidently dead for some time: before applying any other test, the stomach has been opened, and, in consequence of the appearances there observed, further inquiry has been deemed unnecessary—the fact of survival of the birth being indubitable.

Should the bowels be found destitute of meconium, this also would denote that the child had lived for a time. Other distinctive characters, chiefly anatomical, may here be omitted, as we shall have to notice them farther on.

Obvious sign of still birth.—Previously to entering on the important question, whether a new-born infant, found dead, had ever respired or not, it is to be observed, that there are some cases in which it is obvious and proper to presume that the infant *could not* have been born alive—in fact, that it must have died, perhaps some time, before birth. There is one appearance which serves to remove all doubt, namely, that of *uterine putrefaction*.

When a child dies in the womb, and is expelled, as it generally is, after some days, it is found to have undergone changes as striking and as characteristic as if it had been exposed to the open air. There is a looseness and flaccidity of all the structures; the bones, especially those of the head, have no firmness in their union with one another; they yield with their own weight, and that of the contents of the skull. The skin is decomposed, the epidermis peeling off, and when newly removed, leaving the integuments beneath of a bright reddish colour. The belly is generally of a brownish hue, without any mixture of green. The umbilical cord is wholly relaxed, untwisted, and full of a brownish liquor. Beneath the scalp, also, will generally be found an effusion of serum, which has been compared to a thickish raspberry vinegar. It is said that in some instances the dead foetus, ere it has been expelled from the uterus, has been converted into *adipocire*.

But all these appearances will be better appreciated by an experienced eye, or by a person who has even only once or twice observed them, than from any mere description. The preceding detail applies to the case of the dead infant not being expelled for several days; but suppose the infant born on the same day, or the day after, it has died—what then becomes of our indubitable sign? It does not hold good: we can then only have recourse to the ordinary tests of live or still birth.

Has the Infant respired?

This, after all, is usually the main question to be determined, where the inquiry is, in *criminal* cases, whether the infant was born alive. In *civil* cases, as I have already observed, where tenancy by the courtesy of England is at issue, it is sufficient proof of live birth that the infant has exhibited any sign of voluntary motion; nay, mere muscular irritability seems, in one instance, to have been held decisive. The courtesy of Scotland requires proof that the child has *cried*.

The proofs of respiration are founded on the phenomena which are observed to take place when uterine is changed for extra-uterine life. An alteration occurs in the structure and functions of several parts of the body; but the lungs, the heart, and the liver, are the viscera chiefly affected.

Before proceeding to an internal examination, the *external condition of the chest* ought to be noted. In a child which has never breathed, this part of the body is narrow and flattish; where respiration has taken place, on the contrary, the chest is ample and arched.

Internal Inspection of the new-born Child.

Chaussier, in his *Recueil de Mémoires*, gives some excellent remarks on the opening of bodies, to which I shall have to refer more particularly hereafter. The chest he recommends in all cases, whether adult or infantine, to be laid open as widely as possible, so as to display its contents fully. In the new-born child, the ribs can be most conveniently divided with a pair of scissors, where a saw would have to be employed in the adult. As it is desirable, in many instances, to obtain a view of the contents of both abdomen and thorax at once, the conical-shaped sections of the sides may be continued down to the pubes, so that the whole surface of the trunk may be removed in one piece, in the form of an elliptical flap. In detaching this covering from the cavities, its connexions with the diaphragm must be separated with the scalpel; after which, the umbilical ligament of the liver is to be carefully cut through. The viscera are then freely exposed. Those of the thorax at present demand our attention.

With respect to the state of the lungs, the principal points to be attended to are, 1st, their colour; 2dly, their volume; 3dly, their consistence; 4thly, their absolute weight; and 5thly, their specific gravity.

1. *Colour of the lungs.*—The colour of the lungs of infants born dead is a dark purplish or chocolate hue: some call it a liver colour; and it certainly does correspond with the tints of the adult liver. In a still-born child, also, the lungs are generally found to resemble the thymus in colour; and though the latter is sometimes more pale than the former, yet the comparison is worth attending to: for as the thymus remains unaltered on the occurrence of respiration, or artificial inflation, it affords a sort of standard whereby to judge whether either of these processes has taken place or not. The introduction of air into the lungs completely alters their colour: they become a florid red on inflating them by a tube introduced into the trachea, and natural respiration gives them a bright red or rosy hue. Very frequently, the exact portions of the lungs into which air has been admitted can be easily distinguished from the other parts, by their difference of colour. But it must be kept in mind, that if the lungs be diseased, or gorged with blood, the appearances just mentioned may be greatly modified. On those diseased conditions which may lead to fallacy, I shall subsequently have some remarks to offer.

2. *Volume of the lungs.*—The cavity of the chest of a still-born child presents a very different appearance from that of a child which has been born alive. Where the

lungs have never received air, they appear to occupy but a comparatively small portion of the chest; the pericardium and thymus hold a prominent place in front, while the lungs are placed altogether laterally and posteriorly. This will be better understood from the following figure.

FIG. 25.

In this figure, *a* and *a* represent the horns of the thymus; *b* *b*, the clavicles, with their anterior portions removed; *c*, the body of the thymus; *e* *f*, the lungs; *d*, the diaphragm; and *g*, the pericardium.

On the other hand, the change effected in the volume and situation of the lungs, by the admission of air, may be readily comprehended from this sketch.

FIG. 26.

It will be seen that the pericardium is here nearly covered; the diaphragm is less convex; and the lungs (*d* *d*), in every direction, more voluminous, and largely extending over the latter.

Let it be recollected, however, that in forming a judgment respecting respiration from the volume of the lungs, as well as

from their colour, disease may materially interfere in preventing a diagnosis. Thus the lungs of still born children may be filled with a serous fluid, which considerably increases their volume, and might lead an inexperienced observer to fancy, without further examination, that they were filled with air. In such cases our acquaintance with pathology must come to our aid.

3. *Consistence of the lungs*.—Lungs which have been inflated with air, naturally or artificially, acquire a spongy and crepitant character; they feel soft and light; their edges are rounded off; they appear vesicular, and frothy fluid may be squeezed out of them. Putrefaction or emphysema will also render their surface vesicular; but the vesicles, in this case, are large and irregular, and confined to the surface; being contained, not in the air-cells, but in the cellular substance beneath the pleural lining; and, moreover, the gaseous product of putrefaction, or emphysema, may be totally expelled by pressure, while atmospheric air in the air-cells cannot. The lungs of the still-born are dense, and their edges sharp (particularly the left upper and right middle lobes), and nothing can render them of the consistent and appearance just now described but natural breathing or artificial inflation. If there be reason to know that the latter process has not been had recourse to, the soft spongy feel, the vesicular character, and the discharge of air-bubbles by pressure under water, will strongly indicate that the child has breathed.

4. *Absolute weight of the lungs*.—When respiration begins, it is not merely air that enters the lungs, another fluid gains admittance also—blood which is propelled by the action of the heart. This, by the way, is a circumstance which does not attend artificial inflation, unless it be practised ere the motion of the heart has ceased. But confining ourselves to the effect of the admission of blood into the lungs of the live-born infant, it obviously increases the weight of those organs—is many cases it is found to double it; that is to say, if the lungs, previous to respiration, weighed an ounce (which is about the average weight in the still-born), they weigh, after breathing is established, two ounces. The reason of this change is obvious: the heart of the live-born infant must be always more or less active, and, immediately on the commencement of the new process of inspiring and expiring air, will propel blood into the vessels of the lungs, which had hitherto been unexpanded; the result is, that the respiratory organs are increased in weight (by that of the blood admitted) as well as in volume. But the case is different with the lungs of

the still-born. If, upon the artificial introduction of air into them, their vessels receive *any* blood, they do so only passively: there is no action of the heart to supply them, and consequently their weight is not materially, if at all, increased. Ploucquet, of Tubingen, thought that this change occurred so generally, that it would afford a good test of the fact, whether respiration had or had not taken place. He accordingly, about the year 1777, founded upon it and proposed what is commonly called

The Static Lung Test.

Ploucquet's device was to compare the absolute weight of the lungs, with that of the body, of the infant; and in doing this, he found that, in the case of still-born children, the lungs were no more than about one seventieth of the weight of the body, while, in the live-born, they weighed one-thirty-fifth. From this he inferred that respiration doubled their weight.

But his inference was deduced from too few facts to warrant its general acceptance as a truth. Other observers and experimentalists came after him, and found that his conclusion was not very correct. Schmidt, at Vienna, and Chaussier, at Paris, entered into a special scrutiny of the nature of the true ratio, and the result of their researches (for they correspond pretty closely) has been, that, in the still-born, the average weight of the lungs is about one-fiftieth of the weight of the body, while, in the live-born, it is the one-fortieth. M. Devergie, who has still more recently inquired into the subject, thinks that the averages would be more exactly stated at $\frac{1}{51}$ and $\frac{1}{41}$.

CLINICAL LECTURES,

DELIVERED AT THE

MEATH HOSPITAL AND COUNTY OF DUBLIN INFIRMARY,

During the Session 1836-7.

BY PROFESSOR GRAVES.

LECTURE V.

Treatment of Typhus fever—Tympanites often the consequence of inattention to diet, or to overdosing with purgatives—Thirst in fever frequently dependent on the state of some internal organ—Blisters, employed as stimulants or evacuants, excite the vital action of the capillaries—An important remedy where cerebral affection is apprehended—Signs of approaching cerebral symptoms—Tartar emetic solution, and ointment—The latter used with success in some desperate cases.

BEFORE I proceed to speak of the diet and remedies to be employed in the treat-

ment of typhus, allow me to make a few observations. There is a patient at present in the fever ward, whose case shows the necessity of strict attention and incessant watchfulness on the part of those who have the management of bad cases of fever. A man who has been labouring under delirium, with symptoms of cerebral excitement and congestion, was ordered the tartar emetic solution, with the view of reducing the increased vascular action; but on inquiry this morning, we find that he has taken no medicine, and that his symptoms have been allowed to go on unchecked for twenty-four hours. He refused to take his medicine, and the nurse very improperly neglected to report the circumstances of the case, in order that proper steps might be taken to remedy so dangerous an omission. Thus a whole day has been lost at a most critical and important period of fever. There can be no excuse for such negligence as this, for it could be easily remedied. Patients in this state have always more or less thirst, and a spoonful of the tartar emetic solution could be mixed with whey or cold water, and administered in this way without his knowledge, or if he refused to drink any fluid, it might be given in the form of enema. There is no excuse, therefore, for such negligence; and when you recollect the state that such patients are in—their nervous excitement, incessant raving, agitation, struggling, and sleeplessness—you will be able to appreciate the dangerous, and even fatal, consequences that may arise from culpable neglect of this kind.

At our last meeting I spoke of the use of food and drink, and laid before you my views of the most appropriate articles of diet in the various stages of fever. I told you that I attributed much importance to the use of a proper regimen, and that I looked upon the observance of this principle as a main cause of success in the treatment of typhus. I think it is chiefly owing to our care in this respect, that so few of our patients have tympanites. Now and then we have cases of fever with tympanites and diarrhoea, but in the majority of instances, these are persons who have been under treatment before admission, and who have been too much purged. The use of drastic purgatives in the early and middle stages of typhus, is one of the most fertile sources of subsequent evil, and there are few evils of greater magnitude than tympanites with diarrhoea, and gastro-enteric inflammation, particularly in the latter stage of fever. Now, if you inquire into the history of the cases in which these symptoms are most distinctly marked, you will find that in at least two-thirds, powerful cathartics have been

employed, not once, but repeatedly, in the commencement of the disease. Almost all cases, in which calomel and colocynth, or aloes, followed by black draught, have been liberally used in the commencement, become tympanitic, frequently at a very early period. The same mischief, but in a less degree, is apt to occur where a system of strict abstinence has been enforced, and continued undeviatingly for a considerable length of time. Want of food, even in the healthy state of the system, is apt to produce flatulence, weakness, and distention of stomach, and in many instances gives rise to very serious forms of gastro-intestinal irritation. The *diète absolue* is very apt to produce the same effect in fever. Even the abuse of drinks of the simplest and most innocent description, is apt to produce flatulence, distension, and a tendency to tympanites. Hence the value of the rule which I laid down in a former lecture, viz. to allow the patient only small portions at a time, and to order him to swallow them slowly. The abuse of the ordinary drinks, as common water, whey, barley-water, soda and Selzer waters, and effervescing draughts, is a frequent source of tympanitic swelling in fever. In this hospital we seldom prescribe effervescing draughts, and never give them in the *ad libitum* quantity which some persons recommend. Thirst can be sufficiently assuaged by the use of whey, or common water, acidulated with currant jelly or raspberry vinegar, given in small portions, and at certain intervals. Sometimes you will succeed effectually in controlling feverish thirst by the use of a very light infusion of cascarrilla, acidulated with a small quantity of muriatic acid. I have seen this employed with success by Mr. Kirby, and I have often prescribed it myself with the best effects. Very often you will find that a small quantity of some light bitter, slightly acidulated, will appease the morbid thirst of fever more effectually, and for a much longer period, than large draughts of water, or any of the fluids usually employed for the same purpose. You should always bear in mind, that thirst in fever does not exclusively depend on a dry or parched state of the mouth or fauces, but lies much deeper in the system, and has its origin in some peculiar derangement of the nerves, most probably of those belonging to the ganglionic system. In going through a fever ward, you will meet with numerous illustrations of the truth of this position; for you will find one man with a moist tongue and fauces, and yet labouring under insatiable thirst, while you will observe another with parched tongue and throat, and yet without any desire whatever for fluids, or any

choice as to their temperature. We had two examples of this in the fever ward during the past week. One patient with a moist tongue was incessantly calling for drink, while another man, who had his tongue almost perfectly dry, exhibited a very remarkable indifference to fluids.

There is one curious circumstance connected with the sensation of thirst in inflammatory diseases, which deserves attention. I lately attended a fatal case of metritis after delivery, in consultation with Mr. Hayden and Dr. Ireland. These gentlemen pointed out to me the singular fact, that the patient's thirst was instantly increased to an intolerable degree, by pressure applied to the womb. I merely notice the fact here as being extremely curious, leaving the explanation of it to those who are more conversant with such investigations.

Having said so much of food and drink in fever, I come now to speak of external and internal remedies, and first of blisters. Blisters are employed in a variety of diseases, but are followed by very different physiological effects, and capable of serving very different purposes, according to their mode of application. In fever they are generally employed either as stimulants, or as evacuants and derivatives. As stimulants, they may be used with the intention of rousing the depressed energies of the system in general, by their action on the nervous and circulating systems, or of stimulating the torpid functions of some particular part or organ. With this object in view, they are applied as flying blisters — that is to say, for a space of time not exceeding two or three hours, and solely with the intention of producing a stimulant effect. You have seen some cases of fever in our wards, in which the powers of life were greatly depressed, the extremities cool, the action of the heart feeble, the pulse weak, respiration short and imperfectly performed, and a tendency to faintness and sinking; and you have observed that in such cases we derived great benefit from the application of flying blisters over the region of the heart, the epigastrium, chest, and inside of the legs and thighs. We applied our blisters in these situations, left them on for two or three hours, and then removed them; and you have seen them, when employed in this way, succeed in rousing the vital energies, the depressed action of the heart and capillary system, and the flagging state of the respiratory function, as shewn by the increased strength of the pulse, the more general diffusion of heat, and the renewed play of the various functions.

In such cases, where the stimulant effect alone is required, it would be wrong

to leave the blisters on longer than two or three hours; it will be quite sufficient if they prove merely rubefacient, or, at most, vesicate so slightly as to give to the blistered surface the appearance of a miliary eruption. Here you have all the stimulant effects of blistering, but not followed by their debilitating consequences. You are aware that blisters applied in the ordinary way have a twofold effect; they first rouse, and then depress; acting primarily as stimulants, and secondarily as evacnants. They first act as stimulants, producing pain, heat, and redness of the part; after a few hours these symptoms diminish, and are followed by an effusion of serum—in fact, a quantity of white blood is abstracted from the cutaneous capillaries, and in this way an evacuation is produced, calculated to diminish any accidental congestion in neighbouring parts. The capillaries, by means of their increased action, draw a quantity of white blood to the part; and in saying this, I think I am only using a perfectly physiological expression; for the quantity of circulating fluid in any part of the body must depend on the vital action of the capillary vessels of that part. It is to the peculiar state of the capillary vessels that the quantity of blood in any part is to be referred, and not to the force or frequency of the heart's action. It is by means of changes produced in them that the phenomena of active congestion and inflammation are produced: the capillaries of the affected part enlarge, increase in number, and multiply, and those which were invisible become visible. These phenomena have been falsely attributed by Hastings and others to debility and impaired action of the capillaries.

Enlargement or distension of the capillary vessels, whether the result of active local congestion or inflammation, is quite a different process, and bears a very close analogy to the enlargement of the anastomosing arteries of a limb in which the principal vessel has been tied. The afflux of blood, and the vascular distension, are not the consequences of debility or of relaxation, but of an actual increase of vital action. In the enlargement of the anastomosing arteries which takes place in cases of collateral circulation, the increase of size is not confined to the arteries connected with the main trunk; it commences simultaneously in the more distant set of branches, beginning in the smaller ones, and then gradually extending to the larger. This is a proof that the enlargement of the vessels depends solely on a vital action inherent in themselves, and is not the result of a mere passive distension, or of an increased determination of blood

to the part, produced by the action of the heart.

Dr. Houston, in a very important paper on the circulation in a monstrous foetus, without head or brain, published in the last number of the Dublin Medical Journal, has proved almost to a demonstration, that, in the case referred to, the circulation in the placenta could not be carried on, unless by the vital attractive power of the capillaries. It is owing to this power that vascular tumors bleed so profusely when wounded or scratched; and yet, if you cut through the artery which supplies them, there will not be any considerable hæmorrhage. When you divide the artery, the capillaries cease to draw blood to the part, and the hæmorrhage is slight; but if you wound the tumor itself, the blood is attracted to the part as fast as it drains off, and a profuse hæmorrhage is the result.

You should also bear in mind, that there are many animals which are without a heart, and yet in which the functions of the circulation are adequately performed. We have numerous instances of human monsters born without any trace of a heart, and yet well nourished and developed. In cases of this description how is the circulation carried on, or by what power is the blood impelled through the vessels? I do not see what cause we can refer it to, except the vital agency and attractive power of the capillary system. I mention these facts because, in the treatment of inflammatory and febrile affections, it is important that you should have correct physiological views, and that you should bear in mind, that each part and organ of the body may have its vital action deranged, or, in other words, may become congested and inflamed, independently of the action of the heart or the general circulation.

Blisters, then, produce first increased action of a part, and then act as evacnants. They also stimulate the system generally; but if left on until full vesication is produced, they act as evacnants and depletives, and lower the general tone of the economy. I have frequently observed this succession of events in chronic cases, in which it was found necessary to blister repeatedly during the course of the disease. The patients generally told me that they felt better and lighter on the day on which the blister was applied, but on the next day they usually felt weaker and more depressed; and this state sometimes lasted more than a single day. You may therefore apply blisters as excitants and stimulants, or you may employ them as evacnants and depletives; yet there are many persons who seem to forget this dis-

tion. If in a case of inflammation, occurring in a low state of the system, you propose to apply a certain number of leeches over the inflamed organ, they say no; but they have no hesitation in applying a large blister, leaving it on until it produces full vesication, and thus abstracting a considerable portion of white blood from the system.

You will not expect me to lay down any general rules for the use and application of blistering in fevers; you will find all these matters sufficiently explained in your books and manuals. I am not giving any thing like a regular outline of the treatment of fever; in fact I pass, *per saltum*, from one point to another, without any attention to order or method. You can read methodical treatises, and then compare them with such detached observations as I shall make. And here allow me to make some detached observations on that peculiar state of the brain which we most commonly observe in the middle stage of typhus, and in which blisters form one of our most efficient, and in some instances our only mode of relief. In many of the cases of typhus which come under our observation in hospital, we frequently meet with a train of symptoms strongly calculated to perplex and puzzle, and which should seldom exist in fever regularly treated; these are chiefly cases which are admitted in the middle or latter stage of the disease, and at a period when the patient's state of intellect is such as to preclude the hope of obtaining any satisfactory information from a personal examination.

A man in the lowest class of life, and at a distance from medical aid, is attacked with fever; for the first eight or ten days he is either improperly treated or altogether neglected, and in this state symptoms arise and superinduce others, giving rise to the most unfavourable complications, and rendering the cure difficult, if not impossible. Now of all the symptoms which occur in cases of fever, where the state of the principal organs has been neglected, there are none more formidable, or more fatal, than the cerebral; nor is there any local affection in fever, in which the value of prevention is so unequivocal and decided. What I wish to impress upon you is, that you should always anticipate the cerebral symptoms in fever. Never allow the cerebral symptoms to explode—watch the first scintillæ of cerebral excitement—repress the commencing mischief, and do not allow your patient to be overtaken by formidable inflammation of the brain. This is one of the points in which I have changed my practice. I never allow cerebral symptoms to become established in any of the cases which I

have treated of late. Every writer will tell you that when the patient's face is flushed, his eyes suffused, and when he complains of headache and intolerance of light, you should leech and blister his head, give him purgatives, tartar emetic, James's powder, and the medicines calculated to bring down cerebral excitement: but a careful and observant practitioner will anticipate all these symptoms, although there is as yet no particular flushing of the face, headache, or suffusion of the eyes; and though the patient is still quite rational, he will recognize threatening disease of the brain long before it commences, and take proper steps to prevent its explosion. Watch the functions of the brain attentively, and they will inform you, in almost every case, of the approach of cerebral symptoms. You will find in patients who are about to have cerebral symptoms, a degree of restlessness, anxiety, and a higher degree of energy, than accords with their condition; and they either do not sleep at all, or their sleep is broken by startings and incoherent expressions. When you speak to a person in this state, he answers in a perfectly rational manner; he will tell you that he has little or no headache; and were you to be led away by a hasty review of his symptoms, you would be very likely to overlook the state of the brain. If you inquire closely, you will find that he scarcely ever sleeps, or even dozes—that he is irritable, excitable, frequently incoherent, and muttering to himself. Under such circumstances, although there is no remarkable heat of scalp, suffusion of the eye, or headache, I am frequently led to suspect the supervention of cerebral symptoms, particularly about the ninth or tenth day of the fever (for it is generally about this period that cerebral symptoms begin to manifest themselves); and whenever I observe these premonitory indications, I never hesitate in taking proper measures to anticipate the evil. I immediately order the hair to be shaved off, and blister the whole scalp. Thus, at the period when disease of the brain would most probably have set in, I have the whole external surface of the head pouring out serum, or even suppurating: and when by this treatment I have opposed a barrier to the further progress of the disease, the exhibition of a little tartar emetic will soon remove every trace of it. In laying down this plan of treatment, I have supposed that the patient has been properly treated from the beginning, and that the earlier symptoms of inflammatory excitement have been combated by bleeding, leeching, and other appropriate depletory measures.

There is, on the other hand, an opposite

late of the patient, which in like manner informs me that danger to the brain is at hand. In this case, the patient is almost continually sleeping. When you enter his chamber in the morning, and ask how he does, his attendant generally tells you that he has passed the night most favourably, and that he has slept without almost ever waking since your visit on the preceding afternoon. If he awakens to take drink, he quickly drops asleep again, and when you arouse him he looks rather heavy; there is some slight effusion of the tunica arachnoidea, and some appreciable congestion about the external parts of the face and head. Persons in this state, though apparently doing well, and even where they have been properly treated in the beginning, about the ninth or tenth day begin to rave, and exhibit undoubted proofs of congestion and excitement of the brain. Now, in all cases of this description be on your guard, and do not allow symptoms of dangerous import to steal on you. Here you will derive great benefit from the use of blisters. I was lately called to a very remarkable case of this kind, at some distance from Dublin. The patient slept almost constantly, and complained of no headache or heat of scalp. From an attentive examination of the case, however, I was led to predict the approach of cerebral symptoms. Observe, this was a case of spotted fever; and in this form of fever you can predict the occurrence of such symptoms with a greater degree of confidence. The patient's pulse was 96, his tongue presenting nothing worthy of remark, his behaviour and speech rational, and his sleep almost constant. Recollecting, however, the period of the fever, and observing carefully the condition of the cerebral functions, I had his head shaved and blistered. Notwithstanding this precaution, his cerebral symptoms had proceeded so far that he subsequently got a slight attack of paralysis of the face and tongue, accompanied by a fixed state of the pupils, which would neither contract nor dilate. After having blistered his head extensively, I gave him the tartar emetic solution, to the amount of one-eighth of a grain every second hour. These measures were completely successful in removing the cerebral symptoms, and I have no doubt that the active precautions which had been taken were the means of saving his life.

Now there is one symptom connected with cerebral excitement in fever which is well worthy of your notice, as its existence is often sufficient of itself to give timely intimation of the approach of irritation or inflammation of the brain. This is, the state of the respiratory function. In fever, the breathing will often announce the approach of cerebral symptoms for

days before their actual occurrence. When, in cases of typhus, you find the patient's breathing permanently irregular, and interrupted by frequent sighing — when it goes on for one or two minutes at one rate, and then for a quarter or half a minute at another rate, you may rely upon it that sooner or later an affection of the brain will make its appearance. You will frequently observe the same kind of breathing preceding attacks of apoplexy and paralysis, and indeed it was the occurrence of this symptom, in these and other cases in which the functions of the brain were deranged, that first drew my attention to this kind of breathing. The first time it engaged my attention was in a remarkable case of an apoplectic nature, which I sat up a whole night to watch. On recollection, I found that I had frequently observed an analogous state of the respiratory function in fever, on several occasions, although its connexion with excitement of the brain had not struck me before. I speak here of irregularity of breathing, independent of any pectoral affection. But when the patient breathes in a permanently irregular manner, at one time at a certain rate, and at another at a different rate, — when his respiration is suspicious and heaving, without any disease of the chest or great debility, — you will have some grounds to suspect the existence of cerebral derangement. I am in the habit of calling this kind of breathing cerebral respiration, because my experience has told me that it is almost invariably connected with oppression and congestion of the brain. To recapitulate: — When you find a patient in fever lying constantly awake, or when, on the contrary, you find him continually slumbering, — when there is a certain quickness of manner and irritability, — and when the cerebral respiration has been noticed for some time, without any concurrent debility or pulmonary disease, — under such circumstances, you may, in cases of maculated typhus, predict the approach of cerebral symptoms; and the period about which they generally manifest themselves, is the eighth, ninth, or tenth day. Now, in cases of this description, — if you have previously used leeches and antiphlogistics to a sufficient extent, — your best plan will be to shave and blister the whole scalp. Dr. Little, of Belfast, and Mr. Kirby, of this city, have fallen into the same train of ideas, and employ blisters at a very early period of the disease, with the view of combating cerebral excitement. In a recent instance, in private practice, I think I saved the life of a young gentleman in Harcourt-Street by extensive blistering of the scalp on the fourth day of fever. We were not accustomed to blister at this early period of fever. Formerly it

was the practice to bleed and apply leeches for several days together, and never to have recourse to blistering until towards the latter stage of the disease. In common inflammation, or in arachnitis, we do not blister until we have carried depletion by the lancet, leeches, and purgatives, as far as the patient's strength will allow. But this is not the case in fever: the cerebral congestion and irritation, or inflammation, (call it which you will), which accompanies typhus, differs essentially from ordinary arachnitis or encephalitis, and requires very often a treatment strikingly different.

One physiological fact connected with sleep may be noticed here. It has been stated by Mr. Mayo, that the pupils are contracted during sleep. This is in itself a very curious fact, and I was anxious to verify it. Now we had an excellent opportunity yesterday morning of trying what the state of the pupil was in two patients who lay soundly sleeping in the fever ward. We came up softly to them as they lay on their backs, and in a most favourable situation for observation, just under one of the windows; and having opened the eye-lids, found that the pupil was actually contracted to the size of a pin-hole. It remained in this state for a while, and then expanded when they awakened. This is a very curious fact, and appears to be a very beautiful instance of the protective care of nature. To protect the eye while we sleep, nature, as it were, draws the curtain, and thus defends the delicate organ from any accidental dazzling, at a period when consciousness slumbers, and is off its guard.

Blisters applied extensively to the shaven scalp, are not only valuable in fever, but also in other diseases, and that under circumstances in which little benefit could be expected. The same effects may be produced by rubbing the whole scalp with tartar emetic ointment; but from the pain and inflammation it produces, this proceeding is seldom adopted. I have, however, occasionally employed it; and on two recent occasions with the most fortunate results. A friend of mine had lost two children from hydrocephalus. About five weeks ago another child, an extremely fine boy, was attacked with symptoms of the same disease. After having laboured for a fortnight under fever, with great restlessness, vomiting, and diarrhoea, he was observed to utter frequently that faint cry which is so characteristic of hydrocephalus, and to roll his head constantly from side to side. These symptoms were soon afterwards succeeded by constant motions of the right arm and leg, and subsequently by paralysis of the opposite side. I was consulted before the paralysis occurred,

and advised the child's father to have the whole of the blistered scalp well rubbed with tartar emetic ointment. The boy recovered completely. I derived also a very striking advantage from the use of the same remedy in a very remarkable epidemic which attacked a family in the neighbourhood of Rathmines, and which was witnessed throughout its whole course by my friend Dr. Burke and myself. One of the family, a young lady, was attacked with symptoms of fever, accompanied by pain in the back of the head and stiffness of the neck. After a few days, symptoms of inflammation of the cerebellum and upper part of the spinal cord became developed. About the seventh day she got strabismus, and soon afterwards was attacked with convulsions: the pupil became permanently dilated, and she was quite blind. I was called to see her at this period, and found her almost in a state of insensibility, with involuntary discharge of urine and faeces, cold extremities, and irregular pulse. Thinking that nothing could be done for her, I was about to leave the room, when I asked the nurse, could she swallow? She replied she could, and immediately proceeded to offer the young lady some drink, which she swallowed without any difficulty. This at once arrested my attention. I said to myself, if this patient can swallow, she must be still conscious, and while she is so, there is a chance of saving her. I ordered the whole of the scalp, which had been previously blistered, to be rubbed with tartar emetic ointment; violent inflammation ensued, and she recovered completely. But the curious part of the case is this:—Her brother and sister were attacked, in exactly the same way, a few days afterwards, although less formidably, and were cured by the same treatment. Shortly afterwards two of the servants got pain in the back of the head and stiffness of neck, followed by signs of an inflammatory affection of the cerebellum and spinal cord. They were treated in the same way, and recovered.

What could be the cause of this peculiar fever, manifesting itself in exactly the same way in all the individuals of the family who were attacked? I endeavoured to arrive at the cause, but could not; and I merely state the facts, without wishing to attempt any thing like an explanation. But the history of this extraordinary form of disease is exactly as I have told you. It has been witnessed by Mr. King and Dr. Burke, and they, as well as myself, were very much struck with the novelty of the phenomena.

A CASE OF

GANGRENE FROM "DISEASE OF THE HEART."

To the Editor of the Medical Gazette.

SIR,

If you deem the inclosed case worthy of insertion in your journal, it is very much at your service.—I am, sir,

Your obedient servant,

WILLIAM CLARK,
Surgeon.

Devizes, Jan. 29, 1837.

Mrs. Brown, æt. 50 years, of rather plethoric habit and florid complexion, was attacked on Saturday week last, whilst walking from her cottage into this town, a distance of about a quarter of a mile, with, as she expressed it, a fluttering of the heart and difficulty of breathing, so severe that she was scarcely able to return home. From that time to Friday last, December 3, she says she did not feel positively ill, but occasionally experienced a sense of suffocation, with a disposition to faintings, and especially so after any exertion, such as walking up stairs, &c. Being, however, an active woman, she continued to perform her daily household duties, and did not call for medical aid.

According to her own account she had previously enjoyed good health, not having suffered from the ordinary complaints of colds, &c. more than other people. On Friday night one of her sons returned home very late, and all the family having retired to bed, she went down stairs without her stockings to open the door for him, and in doing so placed her right heel on the damp brick floor. At that time she was in a profuse perspiration, but did not feel chilled or otherwise ill on her return to bed.

On Saturday morning she rose as usual at eight o'clock. Between ten and eleven, A.M. she had severe pain in her right foot, darting upwards to the thigh; this pain increased until her foot and leg became benumbed, and she told a neighbour she was sure she was "death-struck;" she also had severe pain in her bowels. Mr. Mayo was then called in, who found the foot and leg to the knee cold, and sensation al-

most or entirely gone. She was able to move it slightly. Her pulse was to a remarkable degree irregular, varying from extreme rapidity to the opposite extreme of slowness; at one time strong, at another scarcely perceptible. Her bowels were costive, and had been so for a week previously, having had only one or two stools during that time, and those very scanty, dark-coloured, and foetid. Tongue furred; skin hot, and covered with clammy perspiration; dyspnoea and pain over the region of the heart.

Mr. Mayo conceived that, from the costive state of the bowels, an accumulation of hardened fecal matter might possibly have taken place in the colon, and pressure from this cause might have obstructed the circulation in the limb. No tumor could, however, be found in the right iliac region; there was slight tenderness on pressure. He ordered—

Ol. Ricin. ℥j. statim.

This had no effect on the bowels. At two, P.M. *ol. ricin. ℥j.* with a drop of croton oil, also without effect. At nine, P.M. V.S. ad $\frac{3}{4}$ x. and an injection. This brought away only a small quantity of fecal matter.

R Hyd. Subm. grs. iij. : Ext. Colocynth. c. gr. x. Omni tertiâ horâ.

After taking two doses, the bowels acted freely. The evacuations were extremely foetid and dark-coloured. All this time the leg remained in the same state; bottles of hot water were constantly kept to the foot and leg, and the whole limb wrapped in flannels. A mustard plaster was also applied to the sole of the foot.

Sunday morning.—Mr. Mayo being out of town, I saw the patient at his request. On examining the limb I found it of a leaden hue; from the toes to the knee it was cold, and without sensation. No pulsation could be felt in the popliteal or posterior tibial arteries, but slight action remained in the femoral, immediately under Poupart's ligament. Her pulse at the wrist was very irregular, and not at all synchronous with the action of the heart, the pulsations of the latter being (at times) as three to one of the former. There was no unnatural sound in the heart's action, none that enabled me to name any specific disease of that organ; but there was no pause between the diastole and systole, the

one following the other in rapid and constant succession, or rather, the one seeming to run into the other. It rather appeared as if the heart had not sufficient power to propel the blood through the body, in consequence of its being overloaded. Dyspnœa, with pain over the pericardiac region; no headache or vertigo; the warmth of the left leg perfectly natural. The sinapism had no effect on the sole of the foot.

Four o'clock P.M.—I requested Dr. Seagrim to see the patient with me. The case struck him as being very singular, inasmuch as there was no assignable exciting cause for gangrene attacking that particular limb. He ordered a small blister to be applied over the heart, and a lotion of Tinc. Lyttæ and Opii to be rubbed into the limb. Bottles of hot water and flannels to be continued. A tingling sensation was felt after the application of the lotion.

Monday morning.—The leg was covered with patches, irregular in shape, about the size of a crown piece, of a dark purplish hue, and extending about three inches above the knee, on the inner side of the thigh. The pain being very severe,

R. Mur. Morphis gr. iss. every four or five hours.

Tuesday morning.—The morphine has given the patient a quiet and comfortable night. The patches which existed yesterday have spread into each other, and the whole limb has now assumed a dark leaden hue. The femoral artery cannot be felt. Constant thirst; tongue thickly coated. No headache or vertigo; pulse somewhat lessened as to rapidity, but irregular as before; complains of frequent pains darting from her foot to her thigh. Dr. Brabant saw the patient this morning, with Dr. Seagrim and myself. He was also struck with the singularity of the case, and declared his inability to assign any cause for the want of circulation in that limb. He examined the heart with the stethoscope, and remarked upon its rapid and unusual action, but could not say whether it was primarily or secondarily affected.

Ten, P.M.—The patient lies in the same state; she is composed in her mind, and does not complain of much pain. Bowels not open; pulse rather softer. On the anterior part of the thigh she complains of severe pain when the

part is touched. The jugular vein much distended.

Wednesday morning.—The pulse today is more frequent, and the general symptoms of constitutional irritation more urgent; gangrene has not extended up the thigh, but the leg itself is of darker hue. Complains of darting pains.

Seven, P.M.—Restless and uneasy; pain over the cardiac region. She is, and has been, taking port wine. Dr. Tomkins saw her with me this evening.

Thursday morning, 10, A.M.—There is no improvement; pulse more feeble, and general symptoms stronger; she speaks with difficulty; great dyspnœa. There appears to be contraction of the features, the nose and mouth particularly; there is, and has been, a pallor around the mouth from the beginning, but which is more apparent this morning.

Three, P.M.—About three inches above the knee nature is attempting a line of demarcation; there is a certain hardness and tenderness upon touching it, which truly indicates an attempt at separation. It will be recollected that gangrene has not extended for the last two days. Bowels have not acted.

Ol. Ricini, ℥ss.

Eight, P.M.—Bowels have acted. The patient complains of flatulence; pulse rather stronger; port wine and arrow root *ad libitum*.

Friday morning.—Much the same as to general symptoms; complains of severe pain in the limb. Bowels have again acted; the fæces natural in colour and consistence. Yeast poultices.

Eight, P.M.—The thigh considerably enlarged, without any other symptoms of inflammation. There is no vesication of cuticle; pulse as before, very irregular. The abdomen is distended with flatus.

Ol. Ricini, ℥ss.

Saturday, 11, A.M.—This morning her bowels have acted twice; constitutional irritation diminished; pulse firmer, but irregular. Tongue cleaner, and tolerably moist. Gangrene not extended.

R. Sulph. Quinæ, grs. xxiv.; Mucilag. q. s. Divid. in pil. xii.; cap. i. omni tertiâ horâ.

Wine and arrow root continued.

Eight, P.M.—Continues better; her bowels acted after each pill. A blush

employed, not once, but repeatedly, in the commencement of the disease. Almost all cases, in which calomel and colocynth, or aloes, followed by black draught, have been liberally used in the commencement, become tympanitic, frequently at a very early period. The same mischief, but in a less degree, is apt to occur where a system of strict abstinence has been enforced, and continued undeviatingly for a considerable length of time. Want of food, even in the healthy state of the system, is apt to produce flatulence, weakness, and distention of stomach, and in many instances gives rise to very serious forms of gastro-intestinal irritation. The *diète absolue* is very apt to produce the same effect in fever. Even the abuse of drinks of the simplest and most innocent description, is apt to produce flatulence, distension, and a tendency to tympanites. Hence the value of the rule which I laid down in a former lecture, viz. to allow the patient only small portions at a time, and to order him to swallow them slowly. The abuse of the ordinary drinks, as common water, whey, barley-water, soda and Selzer waters, and effervescing draughts, is a frequent source of tympanitic swelling in fever. In this hospital we seldom prescribe effervescing draughts, and never give them in the *ad libitum* quantity which some persons recommend. Thirst can be sufficiently assuaged by the use of whey, or common water, acidulated with currant jelly or raspberry vinegar, given in small portions, and at certain intervals. Sometimes you will succeed effectually in controlling feverish thirst by the use of a very light infusion of cascarrilla, acidulated with a small quantity of muriatic acid. I have seen this employed with success by Mr. Kirby, and I have often prescribed it myself with the best effects. Very often you will find that a small quantity of some light bitter, slightly acidulated, will appease the morbid thirst of fever more effectually, and for a much longer period, than large draughts of water, or any of the fluids usually employed for the same purpose. You should always bear in mind, that thirst in fever does not exclusively depend on a dry or parched state of the mouth or fauces, but lies much deeper in the system, and has its origin in some peculiar derangement of the nerves, most probably of those belonging to the ganglionic system. In going through a fever ward, you will meet with numerous illustrations of the truth of this position; for you will find one man with a moist tongue and fauces, and yet labouring under insatiable thirst, while you will observe another with parched tongue and throat, and yet without any desire whatever for fluids, or any

choice as to their temperature. We had two examples of this in the fever ward during the past week. One patient with a moist tongue was incessantly calling for drink, while another man, who had his tongue almost perfectly dry, exhibited a very remarkable indifference to fluids.

There is one curious circumstance connected with the sensation of thirst in inflammatory diseases, which deserves attention. I lately attended a fatal case of metritis after delivery, in consultation with Mr. Hayden and Dr. Ireland. These gentlemen pointed out to me the singular fact, that the patient's thirst was instantly increased to an intolerable degree, by pressure applied to the womb. I merely notice the fact here as being extremely curious, leaving the explanation of it to those who are more conversant with such investigations.

Having said so much of food and drink in fever, I come now to speak of external and internal remedies, and first of blisters. Blisters are employed in a variety of diseases, but are followed by very different physiological effects, and capable of serving very different purposes, according to their mode of application. In fever they are generally employed either as stimulants, or as evacuants and derivatives. As stimulants, they may be used with the intention of rousing the depressed energies of the system in general, by their action on the nervous and circulating systems, or of stimulating the torpid functions of some particular part or organ. With this object in view, they are applied as flying blisters—that is to say, for a space of time not exceeding two or three hours, and solely with the intention of producing a stimulant effect. You have seen some cases of fever in our wards, in which the powers of life were greatly depressed, the extremities cool, the action of the heart feeble, the pulse weak, respiration short and imperfectly performed, and a tendency to faintness and sinking; and you have observed that in such cases we derived great benefit from the application of flying blisters over the region of the heart, the epigastrium, chest, and inside of the legs and thighs. We applied our blisters in these situations, left them on for two or three hours, and then removed them; and you have seen them, when employed in this way, succeed in rousing the vital energies, the depressed action of the heart and capillary system, and the flagging state of the respiratory function, as shewn by the increased strength of the pulse, the more general diffusion of heat, and the renewed play of the various functions.

In such cases, where the stimulant effect alone is required, it would be wrong

the blisters on longer than two or three days; it will be quite sufficient if they are merely rubefacient, or, at most, so slightly as to give to the blistered surface the appearance of a miliaria. Here you have all the stimulant effect of blistering, but not followed by debilitating consequences. You are aware that blisters applied in the ordinary way have a twofold effect; they first excite and then depress; acting primarily as stimulants, and secondarily as evacuates. They first act as stimulants, producing pain, heat, and redness of the surface. After a few hours these symptoms subside, and are followed by an effusion of serum—in fact, a quantity of white blood is abstracted from the cutaneous capillaries, and in this way an evacuation is effected, calculated to diminish any congestion in neighbouring parts. The capillaries, by means of their contraction, draw a quantity of white blood from the part; and in saying this, I am only using a perfectly physiological expression; for the quantity of circulating fluid in any part of the body must depend on the vital action of the capillary vessels of that part. It is to the peculiar action of the capillary vessels that the quantity of blood in any part is to be referred, and not to the force or frequency of the circulation. It is by means of changes in them that the phenomena of congestion and inflammation are produced: the capillaries of the affected part enlarge, increase in number, and multiply those which were invisible before. These phenomena have been attributed by Hastings and others to the debility and impaired action of the vessels.

The enlargement or distension of the capillaries, whether the result of active congestion or inflammation, is quite a different process, and bears a very close resemblance to the enlargement of the anastomosing arteries of a limb in which the principal vessel has been tied. The afflux of blood, and the vascular distension, are consequences of debility or of relaxation, but of an actual increase of vital action. In the enlargement of the anastomosing arteries which takes place in collateral circulation, the increase is not confined to the arteries connected with the main trunk; it commences first in the more distant set of vessels, beginning in the smaller ones, and gradually extending to the larger. This is a proof that the enlargement of the vessels depends solely on an action inherent in themselves, and is not the result of a mere passive distension, but of an increased determination of blood

to the part, produced by the action of the heart.

Dr. Houston, in a very important paper on the circulation in a monstrous foetus, without head or brain, published in the last number of the Dublin Medical Journal, has proved almost to a demonstration, that, in the case referred to, the circulation in the placenta could not be carried on, unless by the vital attractive power of the capillaries. It is owing to this power that vascular tumors bleed so profusely when wounded or scratched; and yet, if you cut through the artery which supplies them, there will not be any considerable hæmorrhage. When you divide the artery, the capillaries cease to draw blood to the part, and the hæmorrhage is slight; but if you wound the tumor itself, the blood is attracted to the part as fast as it drains off, and a profuse hæmorrhage is the result.

You should also bear in mind, that there are many animals which are without a heart, and yet in which the functions of the circulation are adequately performed. We have numerous instances of human monsters born without any trace of a heart, and yet well nourished and developed. In cases of this description how is the circulation carried on, or by what power is the blood impelled through the vessels? I do not see what cause we can refer it to, except the vital agency and attractive power of the capillary system. I mention these facts because, in the treatment of inflammatory and febrile affections, it is important that you should have correct physiological views, and that you should bear in mind, that each part and organ of the body may have its vital action deranged, or, in other words, may become congested and inflamed, independently of the action of the heart or the general circulation.

Blisters, then, produce first increased action of a part, and then act as evacuates. They also stimulate the system generally; but if left on until full vesication is produced, they act as evacuates and depletives, and lower the general tone of the economy. I have frequently observed this succession of events in chronic cases, in which it was found necessary to blister repeatedly during the course of the disease. The patients generally told me that they felt better and lighter on the day on which the blister was applied, but on the next day they usually felt weaker and more depressed; and this state sometimes lasted more than a single day. You may therefore apply blisters as excitants and stimulants, or you may employ them as evacuates and depletives; yet there are many persons who seem to forget this dis-

tion. If in a case of inflammation, occurring in a low state of the system, you propose to apply a certain number of leeches over the inflamed organ, they say no; but they have no hesitation in applying a large blister, leaving it on until it produces full vesication, and thus abstracting a considerable portion of white blood from the system.

You will not expect me to lay down any general rules for the use and application of blistering in fevers; you will find all these matters sufficiently explained in your books and manuals. I am not giving any thing like a regular outline of the treatment of fever; in fact I pass, *per saltum*, from one point to another, without any attention to order or method. You can read methodical treatises, and then compare them with such detached observations as I shall make. And here allow me to make some detached observations on that peculiar state of the brain which we most commonly observe in the middle stage of typhus, and in which blisters form one of our most efficient, and in some instances our only mode of relief. In many of the cases of typhus which come under our observation in hospital, we frequently meet with a train of symptoms strongly calculated to perplex and puzzle, and which should seldom exist in fever regularly treated; these are chiefly cases which are admitted in the middle or latter stage of the disease, and at a period when the patient's state of intellect is such as to preclude the hope of obtaining any satisfactory information from a personal examination.

A man in the lowest class of life, and at a distance from medical aid, is attacked with fever; for the first eight or ten days he is either improperly treated or altogether neglected, and in this state symptoms arise and superinduce others, giving rise to the most unfavourable complications, and rendering the cure difficult, if not impossible. Now of all the symptoms which occur in cases of fever, where the state of the principal organs has been neglected, there are none more formidable, or more fatal, than the cerebral; nor is there any local affection in fever, in which the value of prevention is so unequivocal and decided. What I wish to impress upon you is, that you should always anticipate the cerebral symptoms in fever. Never allow the cerebral symptoms to explode—watch the first scintillæ of cerebral excitement—repress the commencing mischief, and do not allow your patient to be overtaken by formidable inflammation of the brain. This is one of the points in which I have changed my practice. I never allow cerebral symptoms to become established in any of the cases which I

have treated of late. Every writer will tell you that when the patient's face is flushed, his eyes suffused, and when he complains of headache and intolerance of light, you should leech and blister his head, give him purgatives, tartar emetic, James's powder, and the medicines calculated to bring down cerebral excitement: but a careful and observant practitioner will anticipate all these symptoms, although there is as yet no particular flushing of the face, headache, or suffusion of the eyes; and though the patient is still quite rational, he will recognize threatening disease of the brain long before it commences, and take proper steps to prevent its explosion. Watch the functions of the brain attentively, and they will inform you, in almost every case, of the approach of cerebral symptoms. You will find in patients who are about to have cerebral symptoms, a degree of restless anxiety, and a higher degree of energy, than accords with their condition; and they either do not sleep at all, or their sleep is broken by startings and incoherent expressions. When you speak to a person in this state, he answers in a perfectly rational manner; he will tell you that he has little or no headache; and were you to be led away by a hasty review of his symptoms, you would be very likely to overlook the state of the brain. If you inquire closely, you will find that he scarcely ever sleeps, or even dozes—that he is irritable, excitable, frequently incoherent, and muttering to himself. Under such circumstances, although there is no remarkable heat of scalp, suffusion of the eye, or headache, I am frequently led to suspect the supervention of cerebral symptoms, particularly about the ninth or tenth day of the fever (for it is generally about this period that cerebral symptoms begin to manifest themselves); and whenever I observe these premonitory indications, I never hesitate in taking proper measures to anticipate the evil. I immediately order the hair to be shaved off, and blister the whole scalp. Thus, at the period when disease of the brain would most probably have set in, I have the whole external surface of the head pouring out serum, or even suppurating: and when by this treatment I have opposed a barrier to the further progress of the disease, the exhibition of a little tartar emetic will soon remove every trace of it. In laying down this plan of treatment, I have supposed that the patient has been properly treated from the beginning, and that the earlier symptoms of inflammatory excitement have been combated by bleeding, leeching, and other appropriate depletory measures.

There is, on the other hand, an opposite

state of the patient, which in like manner informs me that danger to the brain is at hand. In this case, the patient is almost continually sleeping. When you enter his chamber in the morning, and ask how he does, his attendant generally tells you that he has passed the night most favourably, and that he has slept without almost ever waking since your visit on the preceding afternoon. If he awakens to take drink, he quickly drops asleep again, and when you arouse him he looks rather heavy; there is some slight effusion of the tunica arachnoidea, and some appreciable congestion about the external parts of the face and head. Persons in this state, though apparently doing well, and even where they have been properly treated in the beginning, about the ninth or tenth day begin to rave, and exhibit undoubted proofs of congestion and excitement of the brain. Now, in all cases of this description be on your guard, and do not allow symptoms of dangerous import to steal on you. Here you will derive great benefit from the use of blisters. I was lately called to a very remarkable case of this kind, at some distance from Dublin. The patient slept almost constantly, and complained of no headache or heat of scalp. From an attentive examination of the case, however, I was led to predict the approach of cerebral symptoms. Observe, this was a case of spotted fever; and in this form of fever you can predict the occurrence of such symptoms with a greater degree of confidence. The patient's pulse was 96, his tongue presenting nothing worthy of remark, his behaviour and speech rational, and his sleep almost constant. Recollecting, however, the period of the fever, and observing carefully the condition of the cerebral functions, I had his head shaved and blistered. Notwithstanding this precaution, his cerebral symptoms had proceeded so far that he subsequently got a slight attack of paralysis of the face and tongue, accompanied by a fixed state of the pupils, which would neither contract nor dilate. After having blistered his head extensively, I gave him the tartar emetic solution, to the amount of one-eighth of a grain every second hour. These measures were completely successful in removing the cerebral symptoms, and I have no doubt that the active precautions which had been taken were the means of saving his life.

Now there is one symptom connected with cerebral excitement in fever which is well worthy of your notice, as its existence is often sufficient of itself to give timely intimation of the approach of irritation or inflammation of the brain. This is, the state of the respiratory function. In fever, the breathing will often announce the approach of cerebral symptoms for

days before their actual occurrence. When, in cases of typhus, you find the patient's breathing permanently irregular, and interrupted by frequent sighing — when it goes on for one or two minutes at one rate, and then for a quarter or half a minute at another rate, you may rely upon it that sooner or later an affection of the brain will make its appearance. You will frequently observe the same kind of breathing preceding attacks of apoplexy and paralysis, and indeed it was the occurrence of this symptom, in these and other cases in which the functions of the brain were deranged, that first drew my attention to this kind of breathing. The first time it engaged my attention was in a remarkable case of an apoplectic nature, which I sat up a whole night to watch. On recollection, I found that I had frequently observed an analogous state of the respiratory function in fever, on several occasions, although its connexion with excitement of the brain had not struck me before. I speak here of irregularity of breathing, independent of any pectoral affection. But when the patient breathes in a permanently irregular manner, at one time at a certain rate, and at another at a different rate, — when his respiration is suspicious and heaving, without any disease of the chest or great debility, — you will have some grounds to suspect the existence of cerebral derangement. I am in the habit of calling this kind of breathing cerebral respiration, because my experience has told me that it is almost invariably connected with oppression and congestion of the brain. To recapitulate: — When you find a patient in fever lying constantly awake, or when, on the contrary, you find him continually slumbering, — when there is a certain quickness of manner and irritability, — and when the cerebral respiration has been noticed for some time, without any concurrent debility or pulmonary disease, — under such circumstances, you may, in cases of maculated typhus, predict the approach of cerebral symptoms; and the period about which they generally manifest themselves, is the eighth, ninth, or tenth day. Now, in cases of this description, — if you have previously used leeches and antiphlogistics to a sufficient extent, — your best plan will be to shave and blister the whole scalp. Dr. Little, of Belfast, and Mr. Kirby, of this city, have fallen into the same train of ideas, and employ blisters at a very early period of the disease, with the view of combating cerebral excitement. In a recent instance, in private practice, I think I saved the life of a young gentleman in Harcourt-Street by extensive blistering of the scalp on the fourth day of fever. We were not accustomed to blister at this early period of fever. Formerly it

15th.—Patient called to inform me that the wound was quite healed. I examined the part, and found the cicatrix firm and complete. Patient observes that she sleeps well; that her appetite is good; that her catamenia recur with regularity and without pain; that she is as stout and strong as before becoming pregnant; and, in short, that she never was in a better state of health.

Nov. 16th.—I saw her yesterday; she continues in the enjoyment of good health.

Remarks.

By extra-uterine pregnancy is meant the development of the foetus out of the cavity of the uterus. At the period of impregnation, the ovum, instead of being transferred to the uterus, according to the natural process of gestation, is either detained in the ovarium, or, at its expulsion from the ovarium, escapes into the cavity of the abdomen, where it lodges; or, on leaving the ovarium, is detained, *in transitu*, by the fallopian tube. These constitute the three different species of extra-uterine pregnancy which are generally enumerated by writers; the first of which is termed *ovarian*, the second *ventral*, and the third *tubal*. Dr. Ramsbotham mentions the existence of a fourth species, which he terms *utero-tubal*, where the foetus lodges in the uterine portion of the fallopian tube.

Burns, in his Principles of Midwifery, observes, that “of all the species of extra-uterine pregnancy, the tubal is the most frequent, and the ventral the most rare.” Dr. Davis, in his work on Operative Midwifery, has entered largely into the subject, and refers to about ninety recorded cases of extra-uterine pregnancy, in which list the proportion of the several kinds are as follows:—

Ventral	9
Ovarian	16
Tubal	40
Of pregnancies extra-uterine, } but of uncertain locality . . }	24

“All the cases of ventral gestation, which are not numerous, and of the existence of which, as a special variety of extra-uterine pregnancy, some writers have expressed great doubts, have, without a single exception, terminate fatally within the period of gestation, and the greater number within the earlier weeks.

tion, and the greater number within the earlier weeks.

“All the examples of ovarian gestation terminated fatally, and the greater number at an early period. One had arrived at the fourth month, and another, that of Forrestiers, at the sixth or seventh month of gestation.”

Tubal pregnancy is commonly fatal from about the sixth week to the third month, the tube giving way by ulceration, and the patient dying from hæmorrhage into the peritoneal cavity. “The subjects of about one-fourth of the whole number,” according to Dr. Davis, “survived the full period of gestation.”

“Amongst the results of cases under the last division of extra-uterine conception, viz. that of uncertain locality, we have happily many examples of recovery after years of various affliction from the presence of extra-uterine cysts within the peritoneal cavity.”

From the nature of the fluid discharged on tapping, which was of a chocolate colour, thickish, and similar to the fluid met with in some diseases of the ovarium, I was at first induced to consider this a case of ovarian gestation; but on more mature deliberation, and for the following reasons, I am at present inclined to place it under the head of ventral gestation.

1st. We know that of the recorded cases of extra-uterine pregnancy which have attained the full period of development, the greater number belong to the class of ventral gestation.

2d. The locality of the foetus in the present instance was very high up in the abdomen, and from its lying transversely, with the head to the left side, we might naturally suppose, if it had belonged to the ovarian division, that it would, during its development, have been more likely to have been situated lower down, towards, and perhaps occupying some portion of, the pelvis.

3d. The sac was well circumscribed, as far as could be ascertained from the finger being passed into and moved over its inner surface.

4th. During the performance of the operation, nothing but the abdominal parietes and the foetal sac were divided.

The assigned causes of extra-uterine gestation seem altogether hypothetical; a state of things as might give the occurrence is very readily

conceivable, when we consider the minuteness and consistence of the germ, the smallness of the tube through which it ought to pass, and the complex nature of the gestative apparatus; and surprise might naturally be excited in the occurrence of so few cases of this particular deviation from the ordinary course of nature. Imperviousness of the fallopian tube, produced after impregnation, from whatever cause; adhesions between the sides of the tube and other parts; malformation; fright at the time of conception, &c. are mentioned amongst the probable causes.

Treatment.

The cases of extra-uterine pregnancy on record in which recovery has been effected, are not very numerous. This fact may be accounted for from the extreme difficulty of forming a correct diagnosis, in conjunction with the comparative variety of these cases; the fatality may likewise have been increased by the prejudice which has hitherto pretty generally prevailed, in regard of making incisions into the peritoneal cavity, under the dread of inducing fatal inflammation of this membrane—a dread which has perhaps been the principal stumbling-block to the advancement of abdominal surgery, (especially in this country) notwithstanding the vast importance of the subject*.

That the assertion in reference to the expression prejudice is well founded, will, I think, be amply supported by referring to the experiments and opinions of Dr. Blundell, embodied in his work entitled "*Researches, Physiological and Pathological*," undertaken with a view to the improvement of the surgery of the abdomen in the human being.

Dr. B. instituted a series of important and valuable experiments on rabbits; amongst these the following may be mentioned. From some rabbits he removed the left kidney, from others the spleen; in some he punctured the fundus vesicæ, and tied the aperture with a ligature; in two he cut off at least one quarter of the bladder at the fundus,

&c. &c.: some of the rabbits in each of these experiments completely recovered.

Dr. B. infers, I think fairly, from these experiments, that large apertures into the peritoneal sac in the rabbit are not necessarily, nor perhaps generally productive of fatal inflammation; that the kidney, the spleen, and a large piece of the bladder, may be extirpated without necessarily causing death, though death under the first operation is probable; and that success in the abdominal operations on the rabbit furnishes a presumption in favour of success in similar operations on the human abdomen.

In the treatment of extra-uterine pregnancies, much will always depend upon the character and circumstances of each case; but in the cases which have advanced to or near the ninth month of gestation, does it not seem probable that in some instances much suffering and danger might be avoided by a prompt and early recourse to an operation for the removal of the foetus and appendages, where the diagnosis is sufficiently indicative of the nature of the case? and does not that opinion seem to be both justified and strengthened on referring to the cases of ventral and ovarian gestation detailed by Dr. Davis, all of which, being left to nature, terminated fatally?

We know that in cases which have arrived at the ninth month of gestation, symptoms, from the attempts at expulsion, as in natural labour, manifest themselves also in extra-uterine pregnancy; a little blood comes away, and if the tunica decidua is formed, it is expelled at the same time; would not this occurrence of simulated labour, with a close attention to the sudden remission of symptoms, conjoined with a careful examination of the state of the uterus, lead to the presumption of a correct diagnosis being formed in the generality of cases? For support of the latter position, I must again refer to the testimony of Dr. Blundell, who states, "that a finger or two may be inserted into the uterus at this time, and the absence of the foetus easily ascertained," and which statement is well borne out by the following interesting case, kindly communicated to me by my friend Dr. Blundell.

A woman in the end of a reputed

* *Vide* Burns, who states, "we are justified in the highest degree in trusting to the powers of nature, rather than to the knife of the surgeon."

pregnancy was seized with symptoms of an incipient parturition, and Dr. B. was called in. On making examination, he gave it as his opinion that the womb did not contain a foetus, for both the fundus and the mouth of the uterus could be felt, and the bulk of the organ, not exceeding that of two months, was obviously insufficient for the purpose.

A day or two afterwards, violent parturient efforts supervening, Dr. B. was summoned in all haste, with a hurried intimation that the child would probably be born before his arrival. Of course this intimation was accompanied by a smile and a sneer. On reaching the chamber, Dr. B. found the patient labouring under vehement uterine efforts; but on repeating the examination, the os uteri being open, he succeeded, without difficulty, in introducing the fore finger of the left hand into its cavity, and gently depressing the whole womb by the action of the right hand applied externally upon the fundus, he was enabled to touch the internal surface of the fundus with the tip of the finger already introduced, satisfying himself beyond a doubt that no foetus was there. The size and situation of the womb being in this manner ascertained, together with the absence of an uterine ovum, the abdomen was further examined externally, when, behind the uterus, a large tumor of the size of a nine months' impregnation could be clearly distinguished. Further assistance from Dr. B. was declined; but the patient dying apparently from peritonitis, a *fine foetus* of the size of nine months was found lodging externally to the uterus, and with its cyst forming the tumor.

The stethoscope has been frequently and successfully used in the detection of natural pregnancy; might it not also be employed to assist in forming a correct diagnosis in cases of extra-uterine gestation?

As to the danger of making incisions into the peritoneal sac, though not to be undervalued, yet surely it is not sufficient to set aside the operation, if we refer to the many successful cases of the Cæsarean operation, extirpation of the womb, of the spleen, and of the ovaries, strangulated hernia, &c., &c., as well as to Dr. Blundell's Experimental Enquiries, before alluded to; and we shall have

proof sufficient, that the risk of fatal peritonitis from these incisions has been greatly exaggerated, and that it ought not to deter us from abdominal operations, when the urgency of the case seems to demand them.

The correctness of these inferences being granted, as founded upon the arguments advanced in support of our views relative to the expediency of an operation for the removal of the fetus and appendages in cases of extra-uterine pregnancy arrived at or near the ninth month of gestation, the important question as to the period most eligible for the adoption of such operation presents itself in the next place for our consideration.

The answer to this question properly restricts itself to two periods: the first of which would be indicated by the symptoms of expulsion becoming manifest during the continuance, or immediately after the subsidence, of these symptoms; the second, commencing at the termination of the first period, renders the time of operation less definite, and altogether circumstantial. Let us examine what inducements we have for selecting one or the other of these periods. Now, as to the first, viz. that of the manifestation of the expulsive symptoms, &c I think we may consider the advantages derivable, under three divisions.

1. *The chance of preserving the lives of both mother and child; the latter of which would be only possible at this period, while that of the former would be rendered more probable at this than at any subsequent time.*

That such is not only a tenable but a justifiable anticipation, cannot, I think, be better substantiated than by referring to the many analogous cases of abstraction of the foetus by the Cæsarean section, which have been performed with a happy result. One example to this effect, of recent occurrence, will, it is hoped, serve as an ample illustration of the rationality of the principle. This case is recorded in Part III. of the British and Foreign Medical Review, edited by Drs. Forbes and Conolly, pp. 71, 72, 73.

The Cæsarean section was performed three several times on the same individual, by Dr. Michaelis, of Kiel. On the first operation a dead foetus was ex-

tracted; under the two latter the lives of both children were saved, and the mother recovered and did well*.

2. *The constitutional powers are in a better condition for sustaining an operation, the constitutional irritation being less, and least to be dreaded at this period.*

No further argument need be adduced to support this position, than that the longer the case is protracted, the greater must be the risk of constitutional disturbance and consequent debility, and in the same ratio dangerous to the mother; and this would surely be a sufficient inducement to operate at as early a period as possible.

3. *By operating at such time the occurrence of intestinal ulceration would be obviated, a result not unusual as a concomitant of protracted gestation (extra-uterine.) This untoward event happened in the case under consideration.*

That this circumstance cannot occur for some time after the death of the child, will, I think, appear evident, when we consider the process which nature has to set up for its decomposition; and from analogy we can readily conceive such a condition to be replete with the most imminent danger: this risk, by operating early, would be avoided, and add another powerful auxiliary to the chance of preserving the mother's life.

Thus the intention would be to endeavour by an operation, as near the ninth month as possible, to save the lives both of the parent and her offspring; and although the death of the child might have previously taken place, still the life of the mother would be brought into a position more favourable for recovery.

Let us now consider the second period for operating, viz. that commencing shortly after the termination of the expulsive efforts, and which renders the time for so doing less determinable.

We must be guided by the urgency of the symptoms, and never lose sight of the advantages derivable from an operation, in even protracted cases, as proved in the present instance, where

such an unfavourable event as ulceration of the intestine supervened, accompanied by considerable constitutional irritation; yet the patient's life was preserved, and she regained her wonted good health and faculties.

As to where an incision ought to be made, whether through the abdominal parietes or through the vagina, must depend entirely upon the locality of the fœtus; but in the majority of instances the former situation would be preferable, and I think justly so, because, in operating with a proper degree of care, the free peritoneal cavity might be avoided.

We know that the opposite surfaces of living tissues, more particularly those of a serous character, when brought into close contact in states of inflammation, are apt to become mutually adherent; and thus it is in extra-uterine pregnancy. The sac containing the fœtus occasions some degree of inflammation or irritation, which has the effect of causing lymph to be thrown out, and producing, in tubal and ovarian cases, adhesion between the peritoneum covering the sac, and that portion of it which is reflected over the abdominal parietes; and by the termination of the full period of gestation, the union between the two surfaces is generally complete to the extent of nearly the anterior half of the sac. But in ventral cases, the germ, being lodged in the cavity of the abdomen, separates the two layers of the peritoneum as far as its circumference, where they become united by means of lymph, which forms a boundary, and assists in supporting the proper membranes of the placenta, and in preventing the escape of the contents of the ovum into the free cavity of the abdomen.

In those cases where adhesion has taken place, that part of the abdominal parietes included between the superior and inferior boundaries of the sac need alone be divided; and I would recommend that an incision should first be made, large enough to admit the finger, at that part where fluctuation could be most distinctly felt, for the purpose of ascertaining the extent of the sac; and that the aperture be enlarged accordingly.

Thus, by not laying open the free cavity of the peritoneum, the risk (so much dreaded) of producing inflamma-

* For an excellent detail of this case see the journal just referred to.

tion of that membrane by the extravasation of blood, the effusion of other fluids, or the lodgment of any irritative matter, would be greatly diminished, and the objection raised by Sabatier, in his "*Médecine Opératoire*," as to the danger of extravasation of fluids, &c. into the cavity of the abdomen, would under such circumstances be obviated.

I have been asked how the placenta could be removed without incurring the risk of great hæmorrhage, there being no contractile power, as in the uterus, to close the mouths of the vessels, when the placenta is detached from the cavity of the sac in which it and the foetus are contained?

I should here express my belief that the death of the foetus takes place at, or very soon after, the period when the fruitless efforts at expulsion are made; so that the foetus becomes an extraneous body, devoid of vitality. It may be presumed that the placenta, having no further functions to perform, soon loses its vitality and operates as an extraneous body too, and, on the well-known principle of the animal economy, in analogous instances, occasioning closure of the vessels at that part where the living surface comes into contact with the dead; and this state of things would necessarily preclude the danger to be dreaded from the occurrence of hæmorrhage: but, for the sake of argument, admitting the existence of a vital condition of the contents of the sac, after the separation of the child, this is my answer:—I would not extract the placenta immediately, but would leave it for a few days; when I confidently believe that the usual process of separation would be set up by nature in this case, as is exhibited in the removal of extraneous bodies from the system, or of parts that have become mortified; for, as before stated, the child being separated, and the placenta having no further function to perform, must necessarily lose its vitality and become an extraneous body.

Another question here suggests itself: might not leaving the placenta for a few days, or till its death supervened, in contact with a vital surface, be likely to lead to the same baneful results as occurred under Dr. Wm. Hunter's practice of leaving the placenta in the uterus, in order that nature might complete the process for its expulsion? The only

answer I can, or think need give, to this interrogative, is by referring to what really occurred in the case under consideration, where not only the placenta, but likewise the child itself, were placed in this relation to the living organism, since both had been, at the time of their extraction, dead for nearly five months: still no untoward event or evil consequences resulted; nor yet are we prepared to say how far the analogy between the interior of the sac of an extra-uterine impregnation and of the uterus holds good; but I think we may conjecture, from the results observed in these two instances, that their physiological conditions are very different.

It may be well to observe, in dismissing this case, that the recovery of the patient, under abdominal injury so great, surely gives increased strength to the opinion that the abdomen will bear much, and that an abdominal surgery, cautious, yet more enlarged than the surgeons of the preceding century have ventured to exercise, might not be wholly unattended with success.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALEMBERT.

The Works of John Hunter, F.R.S.; with Notes. Edited by JAMES F. PALMER. In 4 vols. 8vo. illustrated by a volume of Plates, in 4to. Vol. I. Longman and Co.

THE opening of the new College of Surgeons, and the approach of the annual oration consecrated to the fame of Hunter, are epochs happily chosen for the appearance of this work. It is, in fact, a monument to the genius of that master-spirit whose labours and whose creations it records, and can scarcely fail to be acceptable to the profession generally, but more particularly to that great mass of listeners who will shortly be congregated within the walls of the most splendid professional institution, and adjoining the most comprehensive and valuable physiological and pathological museum in Europe.

The first volume (the only one yet published) contains an original and well-written life of Hunter, in which the

unmeasured panegyrics, and the shameless detraction of preceding biographers, are alike avoided. This is followed by "Lectures on the Principles of Surgery," in correcting and preparing which great pains seem to have been taken to collate the best and most authentic MS. copies extant.

The work is altogether one which promises to confer an important service on the profession,—a service which will not be appreciated the less on account of the modest and unassuming manner in which the Editor speaks of himself and his labours.

We shall probably bring some of the most interesting parts of the work before our readers in some future numbers of the GAZETTE.

MEDICAL GAZETTE.

"Licet omnibus, licet etiam mihi, dignitatem Artis Medicæ tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

POOR-LAW TRICKERY PRACTISED ON THE PROFESSION.

IF we have said nothing for some time past on the subject of the vile new Poor-Law and its abominable working, it has not been, heaven knows, for want of material to illustrate its nature, for daily and hourly the examples are multiplied of the mischiefs resulting to the community from this pernicious system; but we began to feel, we must confess, the hopelessness of opposition in a cause which so deeply concerns the welfare of the medical profession throughout the country, as well as that of the public at large, yet in which those who are actually so much interested exhibit themselves so lukewarm.

Since the publication of the excellent report of the committee appointed by the Provincial Association, there has been a dead silence;

we have heard of no steps being taken, or proposed to be taken, in any quarter, to follow up the recommendations of the committee. Parliament is now assembled, yet not a stir seems to be even contemplated in any locality to get up petitions. The session, no doubt, will slip by, as many preceding ones have; and then, in the usual course of things, meetings will be held to complain of grievances, which, with a little more energy on the part of the complainants, might have been averted.

The members of the medical profession seem to be waiting on the will and pleasure of the public, thinking, doubtless, that the frightful examples of inhumanity constantly coming before them will ere long work an abolition of the law. But they miscalculate the effects of such stimulants, which only become weaker in their operation the more frequently they are administered.

What can be more horrifying than the instances every day brought under the recognizance of our magistrates, of wretched people of all ages starving to death, in a country which could hitherto so proudly boast of its provision for the poor? Unfortunate creatures, in the last state of destitution and disease, are hourly besieging the police offices for that relief which the magistrates can no longer order, and the parish overseers deny. Mothers are obliged to carry their dying children in their arms, making application to one overseer after another, and treated with unfeeling brutality by all, until at last the infants perish. A case of this kind is even now before us: a wretched couple, with a sick child, wishing to stop at Brentford, on their way from Croydon, were refused a bed in any of the lodging-houses, lest the baby should die, and thus become chargeable to the Union for its burial: the lodging-house keepers were warned on this point by

the overseers. The consequence was, that the child died in its mother's apron.

Nothing can in general surpass, in the way of cruelty and inhumanity, the conduct of the overseers, relieving officers, and all the functionaries connected with the new system: it would seem, indeed, as if there was something in the measure itself infectious, in this respect, for the *employés* no sooner get into office than they almost invariably become case-hardened, and lost to all sense of shame. There are but few exceptions.

This heartlessness and cruelty, however, are not the only characteristics of the new poor-law officers; their inhumanity and injustice are frequently combined with trickery and insult. In all their dealings, with medical practitioners especially, the Boards of Guardians have displayed a singular propensity for exercising an insulting tyranny: they have bullied and threatened, and have found, unfortunately, in too many instances, that they could thus succeed in carrying their point. That disgusting affair which was transacted at Somerset-house a few months ago, when a poor-law medical officer was thrown overboard as a tub to the whale, to mitigate the public indignation, then at its height, should serve as a warning to all practitioners unhappily tempted to enter their service. But we were not prepared for the gross amount of trickery which the Poor-Law functionaries do not think it amiss sometimes to practise, until we met with a striking instance in a provincial paper. It would seem that wherever the system is introduced, not only, as we have said, are officers procurable endowed, or speedily endowable, with the requisite want of feeling, but these persons soon show that they are everywhere actuated by the same spirit precisely: a Board of Guardians in the remotest corner of Somersetshire is a

physical and moral miniature of the Board in Somerset House; and every little knot of functionaries, however small, has its Chadwick to regulate its proceedings. The same jesuitry and disposition to overreach those who too candidly confide in its deceptive promises, are everywhere observable.

The case to which we more immediately allude is one which has lately occurred near Castle Cary, in the Wincanton Union. On the 6th October last, a carter in the service of the Rev. H. F. Yeatman fell from a waggon and broke his thigh. Mr. Knight, a surgeon, being on the spot, was requested by the overseer of Ashford (to which place the patient was conveyed "for convenience," after a lapse of two hours, during which time he lay in an exhausted state in the open highway) to attend the case. The medical man apparently knowing the sort of people he had to deal with, desired the overseer to apply to the relieving officer for information as to the course to be pursued; whether a union doctor was to be supplied, or he, Mr. Knight, to be recognized as having charge of the case. The answer was, that no decided arrangement could be made before the next meeting of Guardians, when the matter would be laid before them: but that in the meantime Mr. Knight was to see that the man was provided with "what might be required."

The Chairman of the Board was also apprized of the facts of the case, when he wrote a letter to his friend, Mr. Yeatman, to the following effect:—"I am sorry to hear that your carter has met with so severe an accident. The case shall be duly attended to by our Board to-morrow" (observe, this was on the 11th October, five days after the accident), "when your letter, and the letter of Mr. Knight, the surgeon, shall be read by the clerk. As the accident

happened at Pitcombe, where Mr. Gatehouse, of Bruton, is the medical man, it is fair that Mr. Knight should have some remuneration for his professional services."

But what happens when the Board meets at length, six days after the accident? Why, that no order is made either to direct the medical man of the union to visit the patient, or to discontinue Mr. Knight's services. The relieving officer, indeed, paid him one visit during his illness, and the allowance of half-a-crown and a loaf of bread was granted weekly. No arrangement was made, further than has been already mentioned, respecting medical attendance; so that Mr. Knight conceived himself in possession of the case with the full sanction of the Board. But what was his surprise when, upon the cure being completed, and a bill delivered in, amounting to no more than six guineas for his six weeks' attendance, he found that no notice was taken of his application; but at the end of a month a letter was officially written to Mr. Yeatman in these terms, in which one knows not which to admire most, the dishonesty of principle, or the sneering malignity which they display:—"The Board cannot recognize any charge made by Mr. Knight"—"but while they are resolved on this, they are also resolved never to deprive any gentleman of the opportunity of providing medical care and skill for a long-trying and faithful servant, should he have the misfortune of becoming a casual pauper within their union." *Misfortune*, indeed, for any pauper! But what shall we say to the palpable trickery here practised, of refusing a just demand for services which were in the first instance engaged—hired, by one of the overseers, and then continued with the more than tacit sanction of the Board?

The ground on which these worthy

Guardians of the Poor say they cannot recognize Mr. Knight's claim is, that "by so doing they would introduce a most dangerous precedent." A dangerous precedent to abide by the terms of their contract!—for a contract it was, to all intents and purposes—*morally* at all events, if not legally; and Mr. Yeatman, in a letter to the Editor of the Dorset Chronicle, cites a strong case in point, wherein it was decided by Lord Ellenborough, that a parish officer who did not repudiate the attendance of a medical man situated like Mr. Knight, in effect commanded it.

The issue of the affair may be easily conjectured. The Board, of course, did not alter their resolution; and it only remained for the Rev. Mr. Yeatman, if he thought proper, to pay Mr. Knight for his services to the parish pauper. The money was generously paid, at the same time that the hardship of the case has been laid before the public.

Whatever may be the general destiny of this odious and disgraceful Act, its medical merits, we trust, will be put to the test ere long. There is every probability that a parliamentary committee will be appointed in the course of the present month, to inquire into the actual state of medical attendance on the country poor, when we hope that all practitioners who have been witnesses of the iniquitous working of the system, will be prepared to come forward and give their testimony.

PRICE CURRENT OF DRUGS.

In our last number but one we gave a tabular view of drugs on sale in the English market, with their several prices and duties annexed. We wish to say, in reply to several inquiries, that it is our intention to give a similar table in the number for the last week in each month. Thus our subscribers in distant parts of the country, and abroad, will be regularly supplied with a species of information which we have reason to believe they must have long felt as a desideratum.

HUNTERIAN MANUSCRIPTS.

NOTE FROM SIR B. BRODIE.

To the Editor of the Medical Gazette.

SIR,

I HAVE just been informed that, in a weekly medical publication, which I am not in the habit of reading, it has been lately insinuated that I was in some way or another privy to the burning of Mr. Hunter's papers by the late Sir Everard Home.

I take the liberty of stating to the public, through the medium of your journal, and in the most unequivocal manner, that this is wholly and absolutely false. I knew nothing whatever of the transaction until I was made acquainted with it by vulgar report.—I am, sir,

Your obedient servant,
B. C. BRODIE.

14, Saville Row,
Feb. 9, 1837.

[Since the above was received, the *Lancet* of this day has come to hand, in which the same dastardly insinuation is reiterated. The motive which leads the anonymous scoundrel by whom the articles in question are written to choose the present moment for inventing this slander, is too [obvious] to require any remark.—*ED. GAZ.*]

REPORT ON THE
LOWER EXTREMITIES OF A
HUMAN BODY,

FOUND
UNDER MYSTERIOUS CIRCUMSTANCES;
With Remarks.

By G. F. GIRDWOOD, Esq.

[As some labourers were at work in an osier field, close by Cold-harbour-lane, Camberwell, one day last week, they found a large parcel wrapped in sack-ing; and on opening it, discovered the legs of a human being. The police immediately instituted inquiries, and a Coroner's inquest was held on the limbs at Brixton. The result was, that they were identified as belonging, beyond question, to the trunk found some time since in the Edgware Road. Mr. Girdwood read the following report at the inquest, and has been good enough to forward it to us in a corrected

form, thus enabling us to preserve in our pages an authentic account of the three several *pièces de conviction*.—*ED. GAZ.*]

Decomposition has hardly begun. The complete draining of the blood and other fluids from the cut surfaces of the thighs has prevented the formation of red lines along the course of the blood-vessels, so usual as the incipient marks of putrefaction. The cuticle only is removed at those places where the limbs have been in contact with the bag, and a slight moisture bedews the surface where it is so denuded.

The contour of the leg is round, plump, and fleshy; the thigh is full, the knee well formed, and somewhat approximating its fellow; the ankle and foot are well shaped, the plantar arch well turned, the instep high, the toes very regular, except the second on the right foot, which rides a little over the great toe. Altogether, in its general character, it may be said to be a handsomely-proportioned female limb.

On the shin of the left leg there is a blueish red mark, about the size of the hand, which, with a small dark spot, the size of a fourpence, on the calf of the other, are the only discolorations on the surface, except some dirt on the upper parts of the thighs, and stains on the feet and legs of a purple dye, such as are seen on the legs of those who are in the habit of wearing black stockings.

There is a gash, about two inches long, under the knee inside, on the right leg, but which merely separates the skin and cellular membrane underneath. The surface around it is not ecchymosed.

The thigh bone on the right side is, from where it is sawn across, denuded some way down; the flesh is wanting, and appears to have been eaten away.

There is a circular mark of pressure under each knee, such as is seen on those who wear their garters there.

The length of the foot is ten inches and a quarter, the circumference at the broadest part of the left foot is eight inches and three-quarters, that of the right is half an inch more. The circumference of the calf, at its thickest part, is thirteen inches and a half. The length of the whole limb, taken from the sawn extremity of the thigh bone to a plane rested on by the sole of the

foot, is ascertained to be thirty-two inches and a half. The section of the bone in both limbs has been made so alike near to the hip joint, that the nicest examination cannot detect the difference of the eighth part of an inch in the length of either limb.

The upper portions of the thigh bones which were removed from the trunk of the female body found six weeks ago at the Pine Apple Gate, and kept in my possession since, being placed, the left portion to the left femur, and the right to the right, they were found to correspond exactly in all the irregularities of their half-sawn, half-broken surfaces.

The cloth in which the limbs were found wrapped up is ascertained to be the lower half of a grain sack, on which are painted in red the following letters: **SELEY** (on one side) : **RWELL** (on the other) The sack has been apparently used latterly for other purposes than those for which it was at first employed. It is smeared on what has originally been the outside, with paint, principally white, but it has been turned outside in, the surface having the letters on it being that which was inside when discovered with the limbs. In one of the corners was found about half a handful of common deal shavings. The mouth of the sack was tied round with a piece of thick cord, such as is used to tighten bed-sacking, and at intervals along the rope might be seen parts worn, and permanently bent, so as to have a knuckled appearance, as if it had been long kept in a zig-zag direction.

REMARKS.—This third inquiry completes what was left wanting by the two former reports. The legs now discovered in Cold-harbour-lane, and the trunk found at Paddington, and the head taken from the canal at Stepney, are proved to form together an entire human body—that of a female.

We now ascertain her exact stature: an inch and a half is to be added to the ascertained length of the leg, so as to bring the measurement up to the plane of the symphysis pubis. We have thus 34 to add to 33 inches. An inch may be deducted with propriety, to allow for the elongation after death of the vertebral column; and thus we find the height of the female to be 5 feet 6 inches.

The opinion expressed on a former occasion, of the occupation of the agent, or it may be of an accomplice, or the assassin himself, has received

strong confirmation by the present inquiry. In addition to the lines, and cloths, and shavings, formerly noticed, we have now again the trade of a carpenter denoted by the bed-line, the shavings, and the bag smeared with different sorts of paint.

It is possible that the head may have been thrown into the canal in this neighbourhood, and, the hair having become entangled on some hook or nail, been conveyed by a barge to Stepney; but not very probable. Most likely it was thrown in there.

It might almost be considered that some plan was arranged to place the different portions of the body as far as possible apart: certainly, had the Map of London been taken as a guide, and three equidistant points dotted off in the suburbs, none could have corresponded to the angles of an equilateral triangle more exactly than the three different places we have mentioned. The three points are full seven miles from each other: twenty-one miles must therefore have been traversed. This circumstance, with the weight to be carried, would imply that some mode of conveyance had been used; and this, again, would lead one to the conclusion that more than one person had been employed in the matter.

ROYAL INSTITUTION.

Friday, Feb. 8, 1837.

Dr. Grant on the Glandular System in the various classes of Animals.

THE subject chosen by Dr. Grant for the lecture of this evening possessed much novelty and attraction. It comprehended a view of the glandular system as developed throughout the various classes of animals, from the lowest to the highest. But the lecturer judiciously confined himself chiefly to the glands concerned in digestion; he first noticed in a general way the functions of those other glands employed in secreting tears, serous fluid, poisons, &c., and then proceeded to a special description of the organs in the lower animals engaged in the function of nutrition. Dr. Grant proved that all animated beings had a liver, or at least the rudiments of that most important gland. In the simplest form of animal, which seemed to be nothing more than a digesting sac,

the liver existed as a mere follicle. In the *monas termo*, *hydra*, and other infusoria, those numerous stomachs, some of which admitted indigo, and others vermilion and other pigments, are nothing but so many follicles, in which glandular functions subservient to nutrition are performed. The higher we proceed in the scale of animals, the more complicated those stomachs or follicles are observed to become; and what is commonly called a gland is only a combination of follicles. In the lower animals the glandular apparatus, which is essentially liver, is immediately connected with the digestive tube. Among the higher it is only mediately connected, and opens into the alimentary canal by a duct. This is a necessary provision for animals which have to endure long fasts, or have not their food always before them; and hence the reservoir for the secretion of bile, in the carnivora and man, for example. In the human species, which possesses the liver in its highest state of perfection, the organ attains its ultimate condition by passing through a number of phases, from the simple form which it exhibits in the embryo to that observed in the adult man; and all these phases are analogous to conditions found to exist in lower and less perfect animals.

That the brain of the fœtus undergoes successive changes, being at one time that of a tadpole, at another that of a fish—again that of a crocodile, and so forth; and that in like manner the heart of the human fœtus is at first a simple tube, then a cavity, then two cavities, and lastly an organ containing four, resembling in the successive stages the heart of mollusca, fishes, reptiles, &c., are facts familiarly known. But the announcement made by the lecturer to-night respecting the liver, came upon his hearers with considerable novelty. In the human embryo, the first appearance of any thing indicative of the future liver is a mere thickening of the intestine at a particular spot; that thickening then becomes more and more defined, is found to be follicular, glandular, lobular, and at length apart from the alimentary canal, to which it is connected merely by a duct.

Dr. Grant, towards the conclusion of the lecture, gave a short notice of Mr. Kiernan's researches, and endeavoured to show that the consideration of the complex structure of the liver was involved in that of the hepatic duct simply. This duct, he said, was essentially the liver; as, indeed, in every instance the duct is the gland—its ramifications and complications being unessential to its nature.

In conclusion, Dr. Grant gave a sketch of the formation of glands from the *blastema*, and took a rapid view of the structure of the skin, pointing out the immensity of

follicles and glands of which it is composed.

The whole was illustrated with a profusion of diagrams and drawings, which were referred to and removed with the utmost rapidity. It occurred to us more than once during the lecture, and we are sure others must have thought as we did, that it would have been far better—less bewildering, at all events—if Dr. Grant had made a selection of his illustrations, and only presented those to the audience which were necessary to elucidate his subject.

DEATH BY ASPHYXIA;

FROM INHALING THE FUMES OF CHARCOAL.

(Extract of a Letter.)

I HAVE copied out, and take the liberty of sending you, the details of a case, indisputably authentic, as it is grounded on the *procès verbal* made out by the Commissaire de Police of the Quartier, who was the first to enter the premises of the deceased. It is almost like a voice from the grave of one who relates his passage through the gates of death, and, as a case of physical experience, is highly curious.

On breaking open the door of his bedroom, Deal was found sitting in a chair, in the attitude of one asleep; his head reclined on a table before him, on which were also placed a watch, an inkstand, a lamp, a candle (extinguished), and at his feet a pen, which seemed to have dropped from his hand. Two large tubs, which contained a quantity of cluders and some half-consumed charcoal, were in the room, every aperture to which was carefully stopped up. On raising up the corpse of Deal, a paper was discovered, on which the wretched man had described, minute after minute, the gradual progress of his lingering agony.

He begins first by an explanation of his religious tenets; and adds, that he has taken every precaution that his death may produce no sort of embarrassment to his friends. He then goes on to say, that he had conceived it might be useful to the interests of science that the effect of charcoal in producing death might be properly ascertained, and he was further actuated by a wish to prove that his suicide was an act of sane and premeditated intention. I now give you his own words:—

“J’ai été dérangé plusieurs fois. Au Diable les importuns! ils ne peuvent même pas laisser mourir les gens tranquillement. C’est égal! J’allume mes fourneaux, et place sur la table ma lampe, et ma chandelle, ainsi que ma montre, et je commence aussi la cérémonie.—Il est

dix heures quinze minutes. Les charbons s'allument difficilement ; j'ai, cependant, mis sur chacun des fourneaux un tuyau, qui doit aider l'action du feu.

" Dix heures vingt minutes.—Les tuyaux tombent, je les relève ; cela ne va pas à mon idée. Ils retombent encore ; je les replace de nouveau. Cela va mieux. Le pouls est calme, et ne bat pas plus qu'à l'ordinaire.

" Dix heures trente minutes.—Une vapeur épaisse se repand peu à peu dans la chambre. Ma chandelle paroît prête à s'éteindre ; la lampe va mieux. Je commence à avoir un violent mal de tête ; mes yeux se remplissent de larmes ; je ressens un malaise général ; j'éprouve quelque soulagement, à me boucher le nez avec un mouchoir. Le pouls est agité.

" Dix heures quarante minutes.—Ma chandelle est éteinte, la lampe brûle. Les tempes me battent comme si les veines vouloient se rompre. J'ai envie de dormir. Je souffre horriblement de l'estomac. Le pouls donne quatre-vingt pulsations dans une minute.

" Dix heures cinquante minutes.—J'étouffe ! Des idées étranges se présentent à mon esprit. Je puis à peine respirer. Je n'irai pas loin. J'ai des symptômes de folie."

(Here he confounds the hours with the minutes.)

" Dix heures soixante minutes.—Je ne puis presque plus écrire ; ma vue se trouble. Ma lampe s'éteint ; je ne croyais qu'on dut autant souffrir pour mourir.

" Dix heures soixante deux minutes " (Here are some illegible characters traced, and it is probable that, with the last gleam of his lamp, the life of the wretched man was extinguished *.)

FLAGELLATION IN CASES OF POISONING.

[A CORRESPONDENT, a professor in one of our medical schools, has directed our attention to the following case in the third volume of the Medical Repository, published in New York in 1800, which was communicated by Dr. Valentine Seaman, of that city. It will be perceived that the treatment was similar to that used in Dr. Barratt's case, published in No. 13 of the [Dublin] Medical Journal, although we have no doubt that the idea was original with Dr. B.* The following is the substance of the case referred to, which is published merely as an additional proof of the value of the remedy so successfully used by Dr.

Barratt.] "The wife of — Head, in Water-street, had about two hours before swallowed 3j. laudanum, and then lay in a deadly stupor, from which all the efforts of her friends could not awaken her. Attempts had been made to get some vinegar into her stomach, with little effect ; nor did I (says Dr. S.) succeed much better in endeavouring to give a dose of white vitriol. I then procured a small switch, and applied it pretty freely to her arms and shoulders, which were defended only by a thin covering. I also applied some strokes to her legs. In the course of a short time, indeed almost immediately upon the application of the remedy, she roused up, and begged me to desist. She continued for a time much confused, with involuntary turns of laughter. Two scruples of white vitriol were then administered, followed in about fifteen minutes by 3ss. ipecacuanha ; notwithstanding which, and having tickled her throat repeatedly with an oiled feather, it was nearly an hour before she could be made to puke ; however, finally she did puke, and by the assistance of frequent draughts of warm water, her stomach was pretty thoroughly evacuated. By the assistance of her friends she was kept awake, or, at least, slept but little at a time, during the night, and this [next] morning appears entirely recovered."—*Boston Journal* ; and *Dublin Journal of Med. Science*, Jan. 1837.

PORTRAIT OF HUNTER.

HUNTER's friends had long been desirous to engage him to sit to Sir J. Reynolds for his picture ; but he had always hitherto declined to do so, not choosing that it should be done at the expense of others, and thinking the price too high for himself to pay. He was, however, at length induced to comply, chiefly to oblige Sharp, the eminent engraver, who had received much notice from Hunter, and was very anxious to be permitted to make an engraving from Sir Joshua's picture. Reynolds found Hunter a bad sitter, and had not been able to satisfy himself with the likeness, when one day, after the picture was far advanced, Hunter fell into a train of thought, in the attitude in which he is represented in the present portrait : Reynolds, without saying a word, turned the canvas upside down, made a fresh sketch, with the head between the legs of the former figure, and so proceeded to lay on over the former painting the colours of that which now graces the walls of the library at the College of Surgeons. From this portrait Sharp executed his engraving, which is admitted by the best judges to be one of the finest, if not the very finest, specimen of the art ever executed.—*Life*, in new edition of Hunter's Works.

TREATMENT OF INFLAMMATION.

CHALLENGE TO INVESTIGATOR.

To the Editor of the Medical Gazette.

SIR,

SINCE Investigator treats the reply I have made to his censures upon the system of treatment I adopt for inflammatory diseases as mere idle words, I will, with your permission, propose to him, that he should sink all the idle words between us, and come to facts. If Investigator's real object is to arrive at truth, and not to cavil, he will with me embrace the opportunity which the present season affords us of comparing the respective results of our treatment of cases which are sufficiently similar, if confined to those of the prevailing epidemic. Such a comparison, I should think, cannot fail to produce a fair conclusion as to which of our opposite systems of treatment is the more correct, for they cannot both be right. It would save you, Mr. Editor, unnecessary trouble, if Investigator would drop me a line, by post, stating the day he would send his communication, authenticated by his name and address, to your office; mine should be forwarded on the same day, so that they might both appear in the same GAZETTE. This would be the fairest plan; after which there need be no further discussion between us on the subject.—I remain, sir, yours, &c.

H. SEARLE.

Queen's-Place, Kennington, Feb. 6, 1837.

THE LATE DR. LEY.

WE regret to have to record the decease of Dr. Hugh Ley, physician-accoucheur to Middlesex Hospital, and lecturer on midwifery at St. Bartholomew's. He had suffered from rheumatic fever many years ago, and had latterly been frequently subject to rheumatic inflammation of the limbs, with pain and swelling, though not usually so bad as to confine him to bed. The heart had been damaged in one of the early attacks, and progressively became hypertrophied, attended with so much palpitation and distress as to render it difficult for him to attend to business. For some months before his death, the symptoms had been gradually getting worse, but he had recovered a little, and gone down to the house of his father-in-law, Major Kelly, near Stilton, in the hope of farther improvement: here, however, he suffered a relapse, which carried him off on the 24th of last month.

Dr. Ley was a man of skill and talent, well informed in his profession, and having a very remarkable command of language; indeed he was one of the most fluent lecturers and public speakers we ever met with. His professional reputation was without blemish, and his sentiments, on all subjects, were those of a gentleman.

COLLEGE OF SURGEONS.

THE Hunterian oration will be delivered by Sir B. C. Brodie, Bart., at five o'clock in the afternoon of Tuesday next.

The museum will be opened, to the members only, for that day, and on the 1st of March to the members and the public generally.

The library of the new building, it is announced, will be thrown open on the 15th of February (the day after the Hunterian oration) to members and visitors, as usual. A reading-room, for members only, is to be open from 7 until 10 o'clock in the evening, on Mondays, Wednesdays, and Thursdays.

APOTHECARIES' HALL.

LIST OF GENTLEMEN WHO HAVE RECEIVED CERTIFICATES.

February 9, 1837.

William Dalla Husband, York.
Thomas Johnson, Manchester.
James Edward Newall, Aberystwyth.
Henry Laxton, Bristol.
William Cheesewright, Bristol.
James Stephens, Manchester.
Edwin Chabot, Lambeth.
Charles James Jump, Wisbeach.
James Parkerson, East Dereham.
Henry Lacy Pomfret, Manchester.
Richard Baker Bellyre, Audlem, Cheshire.
Thomas Mark Hovell.
John Gilby, Alford, Lincolnshire.
George Kinghorn Prince, Jamaica.
Alfred Baker, Birminghams.

LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE XXI.

INFANTICIDE *continued.* The hydrostatic lung-test—Its origin not ancient—Contravaries to which it has given rise—Haller's testimony to its worth—Dr. W. Hunter's objections—Mode of applying the hydrostatic test—Swimming of the lungs, how far a proof of respiration—Objections answered—Mode of distinguishing between the effects of inflation and respiration—Sinking of the lungs, how far an indication of still-birth—Objections answered—Live-birth without respiration—Modifications of the hydrostatic test—Daniel's—Bernt's—Proofs of respiration from the state of the circulatory apparatus—State of the ductus arteriosus (the Vienna test)—Foramen ovale—Ductus venosus—Whether a test may be founded on the state of the liver?—Conclusions respecting the validity of the several tests.

I CONCLUDED the last lecture with an account of the static lung test, and showed in what manner it was defective. Like most of the tests for determining the question of respiration, it deserves to have but little reliance placed upon it *per se*, but in combination with others it is often capable of giving consistency to the whole, and of contributing a certain portion of probable evidence for or against the fact in question; for which reason it ought never to be neglected in investigations concerning child murder.

We shall now proceed to consider the fifth point to be attended to in examining the lungs of new-born children.

481.—XIX.

The specific gravity of the lungs.—The lungs of still-born children are dense, specifically heavier than water, and therefore sink in that fluid; those of infants born alive, are of a less specific gravity, in consequence of the admission of air, and will float in water. This distinction forms the essence of

The Hydrostatic Lung Test.

History.—This famous test was first proposed towards the latter part of the seventeenth century. There is no reason to believe that any one was previously acquainted with it, though Galen has been erroneously asserted by some to have had some knowledge of it.

Galen knew nothing about it. It is true he notices the change of colour effected in the lungs of the mature foetus; but he does not suggest even this as a means of distinguishing between live and still birth. It were indeed impossible that he could, for he laboured under the most grievous error as to the nature of the change: he considered it not as the consequence of, but *preparatory to*, respiration. According to the great Pergamenian, when the foetus is mature, nature cuts off the supply of red blood to the lungs, and hence, from being of a dark colour and heavy, they become whitish and light,—an admirable provision for their future functions; for as they are to be in a constant state of motion during life, they would be very ill adapted for the purpose, were they to remain like *other flesh*: hence they are supplied with nothing but air, and a very small quantity of thin blood!*

Nor did Harvey know any thing about the hydrostatic lung test. He has the merit, however, of being probably the first who proposed a test of respiration; for he has hinted that the difference of colour

* Galeni Opera Omnia; Περὶ Χρείας τῶν ἐν ἀνθρώπῳ μορίων. Λόγος ιε. Τόμ. ι. p. 62A. Ed. Basil, 1538.

observed after birth might be made a means of distinguishing whether the foetus ever respired or not. I have already pointed out the passage in his work, *De Generatione Animalium*, in which this idea is broached*.

Bartholinus, in 1663, stated the simple fact that the lungs of the still-born are found to sink in water, while those of children that have breathed float. But it was Swammerdam, in 1667, who first explained the phenomenon.

Karl Rayger, however, is distinctly entitled to the honour of being the original proposer of the test. Writing in 1677, in the *Miscellanea Naturæ Curiosorum*, he says, "we have in the swimming of the lungs a proof of the child having survived birth; and in their sinking in water, evidence of still-birth: whence we have the means of convicting the murderess, and of arriving at the truth."

About five years afterwards, Dr. John Schreyer, Physikus at Zeitz, is said to have actually employed the test in a medico-legal case; and already, in the years 1683 and 1684, we find several of the medical faculties in Germany recognizing the hydrostatic test, and ascribing all the credit of it to Rayger and Schreyer.

But opposition was of course to be expected; and, accordingly, we find several able adversaries entering the lists, to shew the insufficiency and the fallacy of the new method of proof. Zeller and Bohn were among the foremost of these. The former chiefly addressed himself to the sinking of the lungs, which he said did not always indicate that the infant was born dead. He mentioned, that he had tried the experiment with the lungs of a lamb which had lived half an hour, and found that they sank. He also stated other experiments, and quoted a case in which the lungs of a child sank, although the grandmother and mother, *on the torture*, declared that the child had cried after birth, when it was put into a vessel of water!

Bohn was the sturdiest, as well as the soundest, of the early opponents of the lung test. He put the question,—whether the lungs of a child which breathed after birth always float, and whether this floating be a sure sign that the child was live-born? The reply, he insisted, should be in the negative; because the lungs of a dead-born infant might, by artificial inflation, be made to swim in water; because further, air might, during birth, make its way into the mouth and lungs of the child; and finally, because putrefaction might render the experiment uncertain. He then proposed a second question,—

whether the sinking of the lungs proved that the child was dead before birth? To this also he replied in the negative; because the child might have been born alive, though it did not immediately breathe; and there are cases in which, though the entire lungs sink, a portion of them will float.

The sophistry of some of Bohn's reasons will hereafter be seen, when we come to consider the objections to the test systematically; but they had their weight when first advanced, and already some of the faculties began to be shaken. The Leipzig faculty, indeed, as early as 1693, pronounced the prudent and cautious decision, "that the swimming of the lungs in water was not always a proof conclusive of the child having been born alive."

Some idea may be formed of the fruitfulness of the hydrostatic lung test as a subject of controversy during the greater portion of the eighteenth century, from the fact that C. F. Daniel, the younger, in a dissertation published in 1780, states the opinions of no less than 107 authorities, who had treated of the proofs of live and still birth up to that year. To enumerate more than a few of these, would be to occupy time that might be better employed. It may be stated, however, that Teichmeyer and Alberti were among those who contributed most signally to the adjustment of the true value of the hydrostatic test. The former confesses that there are cases in which this lung test is not applicable; in which, consequently, the medical jurist can be of little avail, and the result of the inquiry must be left to the legal faculty altogether. Alberti, also, in his excellent dissertation "*De pulmonum subsidentium experimenti prudenti applicatione*; Halæ, 1728," did much towards reducing the proofs of live and still birth to their proper value.

Both Morgagni and Haller recognized the hydrostatic test as capable of affording satisfactory evidence, when managed with suitable caution and discrimination. As early as 1758 we find Haller experimenting on the effects of putrefaction in modifying the results of the test. He shewed that a moderate degree of putrefaction did not prevent the sinking of the lungs of the still-born, but that when more completely decomposed they would certainly float: he advised, therefore, for the sake of security, that other parts of the infant should be immersed in water, when, if they swam, the lungs, it might be concluded, swam also through putridity, and not from air introduced by the process of respiration.

It is important to know what was the final opinion of the great Haller on the hydrostatic test: I shall quote it from his "*Opus quinquaginta annorum*," the edi-

* Lecture I. p. 4, *ante*.

tion of his Physiology on which he laboured till his latest hour. After mentioning that the lungs of birds are not speedily so affected by respiration as to become specifically lighter than water, he says—"But in regard to man, and animals resembling him in structure, a proof which may be safely relied on may be deduced from this phenomenon, showing whether an infant has been born alive and has breathed, or whether it was still-born. We may be sure that a child has survived birth when the lungs float in water; nor can there be any fallacy, unless there has either been artificial inflation, or putridity to a sufficient extent to render the specific gravity of the lungs less than that of water. A small amount of putridity will not effect this, but a considerable degree will. It is in this way that I reconcile the apparently contradictory experiments of distinguished observers. I have myself seen the lungs sink, after they had been for some months in the body of a foetus buried in a privy; and it was the means of saving the accused. When putridity has attained its utmost extent, and every gas has completely escaped, the residue again sinks. Nor shall the medical examiner even then give an erroneous opinion, if, when he sees the lungs float in ~~consequence of supposed putridity~~, he simply ~~takes the trouble of observing whether the other viscera swim also~~. If he find this to be the case, he may conclude that the lungs float, not through air naturally respired, but through gases generated from the tissues, and which may be seen forming themselves in bubbles over the whole surface of the lungs as well as of the foetal body*."

And in the Addenda, published with the 8th volume of the *Elementa Physiologiae*, we find the question thus concisely disposed of:—"The result of all the experiments and observations which have been made on the subject amounts to this—1. That the lungs of a child that has not breathed will sink—unless they be affected with a considerable degree of putridity; and 2. That lungs which once inspired atmospheric air, will swim in water—unless the inspiration have been very imperfect, or some manifest disease have rendered the pulmonary tissue dense."

I have been thus particular in stating Haller's opinions, because they may be considered as representing, if not giving the tone to, those of all the other great authorities of the continent. The hydrostatic test, it will thus be seen, was thoroughly understood in Germany, and a proper

estimate entertained of its value, long previous to the publication of Hunter's tract in this country.

It is difficult to say what was the amount of information which was afloat at this time among practitioners in England, with respect to the proofs of infanticide; but there is reason to believe that there were vague notions of the hydrostatic test to be met with, and that much mischief was done by persons undertaking the application of it without any proper regard to its nature and objects. It was this that gave occasion to Dr. Hunter, in the last year of his life, to draw up a paper on what he called the "Uncertainty of the Signs of Child-murder," but in which his chief object seems to have been, to shew the uncertainty of the hydrostatic test as a proof of respiration. The avowed purpose of the paper was "to save the lives of unfortunate women" who might be exposed to the hazard of capital conviction on insufficient evidence; and never was a superficial sophistical composition attended with more success. Dr. Hunter was very imperfectly acquainted with the nature of the test which he attacked, and has fallen into several errors in the few pages which he devotes to a pretended examination of its merits; yet there was no one to answer him: his authority was all in all in those days; and the paper in question, which was not published till after his death, was looked upon as a sort of last legacy to his countrymen. As such, it has been always received in this country with marked respect; and, being written in a very popular and plausible strain, it has secured for itself almost the rank of a classic with certain of the older members of the bench and bar. No medical man can safely enter the witness box, on a trial for infanticide, without being acquainted with the "celebrated tract of Dr. W. Hunter;" nor need he attempt to appear for the prosecution unless he be able to meet Dr. Hunter's objections.

With a view of laying the case fairly before medical practitioners, and of enabling them to comprehend its intricacies familiarly, I was lately induced to publish a little manual, to which I would beg to direct your attention. It contains the whole of Dr. Hunter's paper, with such observations appended as I thought were necessary to expose and remedy its weak points; and subjoined you will find a summary of the proofs of infanticide, brought up to the present state of medico-legal knowledge*.

In the subsequent remarks on the hydrostatic test, it will rarely if at all be

* *De Corporis Humani fabrica et functionibus*; tom. vii. p. 88, ed. Bern. 1778.

* *The Proofs of Infanticide considered*. London, 1836. Longman and Co.

necessary to refer to Dr. Hunter. All his objections, however (though I should not call them his, for they were proposed by others some eighty or ninety years earlier), are fully considered, and the various bearings of the subject are contemplated to an extent of which he seems to have had scarcely any idea.

Let me give you one short caution ere we proceed. Do not suppose, as many have hastily done, that the hydrostatic test is a test of *infanticide*; it is only a test of *respiration*: the question of *infanticide* must be determined by ulterior considerations. There are many cases of alleged *infanticide*, in which the hydrostatic test is capable of affording no light; but, on the other hand, there are many in which it is fully adequate to decide the essential preliminary point—whether the infant *breathed*; for this is the sign of life which is in general required on trials for child-murder.

Mode of applying the hydrostatic lung test.—In order to apply this test properly, we ought to have a vessel (such as a glass jar) of sufficient capacity to contain both the lungs and heart, and to suffer them freely to float or sink, according to circumstances. Pure river or rain water should be used, and its temperature should neither be too low nor too high—say 60° Fahr. The vessel being nearly full, let the lungs and heart and the thymus be removed from the chest (taking care previously to tie the large blood-vessels), and let the whole be placed in the water together.

We should then observe whether the parts, thus collectively, swim or sink. If the latter, whether they reach the bottom quickly or slowly. The lungs may then be separated from the heart, and tried one after the other, as to their tendency to sink or remain buoyant. They may next be cut in pieces, and examined in detail as to their gravitating properties; and ultimately the fragments may be pressed so as to expel the air as completely as possible.

The general conclusions deducible from the hydrostatic test, are, 1st, that if the lungs swim, the infant *breathed*, or was born alive; 2dly, that if they sink, the infant did not breathe—it was still-born.

(A.) *Swimming of the Lungs.*

If the lungs, wholly or in part, swim, the inference is, that *respiration* to some extent, more or less, has taken place; but there are certain doubts or objections which may be raised, and are to be removed, before our absolute decision is pronounced.

Objections.—(a.) *Putrefaction* may cause the lungs to float. This is true, in certain circumstances: when the lungs are in that state of *putrefaction* in which

gases are abundantly generated, and cannot immediately escape, they are buoyant, and swim in water. But putrid lungs do not always float; they may not be sufficiently putrid, or their putridity may have attained such a degree as to keep them at the bottom, even though they had once contained air in their air-cells. In the latter case, by the way, the hydrostatic test is of no use; and neither will any other test avail; for the infant's body must, in such a state of things, be one mass of corruption.

The attainment of the latter condition generally requires much time; but there are circumstances in which putrescency may be developed sooner than might be expected; as, for instance, where an infant has been immersed in water for a week or ten days, and then is exposed to the air for about four and twenty hours. The viscera undergo rapid decomposition, and the lungs are commonly found putrid. So rapid and energetic is the evolution of gases in adults, under these circumstances, that, as M. Devergie informs us, bodies exhibited at the Morgue are frequently observed to change their position, and common people looking on, are often alarmed, fancying that the movements are voluntary.

But in ordinary cases submitted to the medico-legal examiner—say within a few hours or days after birth—there can be no room for even supposing the presence of putrefaction. In fact, the lungs are known to be among the last, if not the very last, parts of the body which become putrid; and it has often happened, that when the body of an infant has been found in a state of putridity, the lungs have still been fresh, and fit for the application of the proper tests.

When, however, there is reason to suspect that the lungs float owing to this cause, let them be examined; and if putrid gases are really developed, rendering them specifically lighter than water, those gases will be seen, in large bubble-like vesicles, on the surface and between the lobules; whence they may be readily expelled by pressure under water. For greater certainty, the lungs may be cut in pieces, and each piece pressed separately: such pressure will not destroy the buoyancy of the parts, if they have ever received atmospheric air into their cells; whereas they sink at once if they had floated through mere putridity.

(b.) *An emphysematous condition* may cause the floating of the lungs. It sometimes happens that infants suffer violence in the birth; the labour, perhaps, being tedious, and the mother malformed. The sides of the chest may be so pressed against the substance of the lungs as to do those organs injury: they become inflamed and

puffy, containing air in large vesicles on their surface; and this is what some authors call emphysema. When such a state does exist, it may be recognized by the experienced eye, and by the superficial air expelled, as in the case of the putrid gases. No serious obstacle consequently can arise from this cause to the application of the hydrostatic test.

(c.) *Air may have been artificially introduced.*—The static test may be here brought to our aid. Air blown into the lungs of a still-born child never produces all the changes which follow natural respiration. The moment the atmospheric air is admitted into the lungs of a living child, those organs are expanded, and their vessels filled with blood from the heart. Their weight consequently is increased,—doubled, as we have seen in some instances: so that by comparing the weight of the lungs with the weight of the body, a presumption of much importance may be formed.

The appearance of the lungs affords a strong indication. Experiment shows that the lungs of an infant, perfectly still-born, the moment the air is blown into them, undergo a remarkable change both in colour and bulk. Their colour, from being of a dark chocolate hue, becomes a florid or bright scarlet, and their volume, instead of occupying a small portion merely of the contracted chest, is now, by the admission of air, constantly increased. When a blow-pipe is introduced into the trachea, the chest having been previously opened, these striking appearances are immediately produced. But when inflation is attempted by the mouth, the alteration of colour as well as increase of volume are only partial; and this affords one of the distinguishing characters between the two states of the lungs in question. While inflation tried on the still-born infant, with a view to resuscitation, is never found to operate completely the changes just mentioned, natural respiration, especially when the child is born mature, and there is no congenital disorder of the lungs present, renders those organs uniformly of a bright pink or rosy hue, and their volume throughout is augmented.

Again: another peculiarity by which the effects of inflation may be distinguished from those of respiration, is, that strong and energetic pressure will cause to sink every particle of lungs artificially inflated, while no mere pressure, short of absolute breaking up and mashing of the parts, will cause those lungs wholly to sink with which an infant has naturally respired.

We are indebted to Beclard for the first suggestion of the application of pressure;

but Mr. Alfred Taylor, of Guy's Hospital, and the late Mr. Jennings, of Leamington, are entitled to much credit for having, by their experiments, which were conducted independently, and almost about the same time, put the efficiency of the method beyond a question. Both have shown that by wringing the lungs in a strong cloth, the air may be so perfectly expelled from the inflated lungs of a still-born infant, that they shall all and every part of them sink in water: whereas, in the case of lungs that have naturally respired, even the smallest particles still remain buoyant—as long, in fact, as there is any portion of them not completely mashed. Mr. A. Taylor, indeed, does not think it necessary to carry the compression to such an extreme degree*.

The objection that artificial inflation might have been practised, it must be confessed, may sometimes present the medical jurist with more than ordinary difficulty. But the circumstances of the case ought to save him from vexatious and needless investigation. The truth is, that such a plea on behalf of an accused mother is extremely rare, not only because, in most cases, it has no foundation in truth, but because, to render it probable, evidence of many collateral facts ought to be forthcoming. The female who would endeavour to save her child by inflating its lungs, should have given other proofs, besides, of her maternal tenderness: she should not have concealed, at least from some intimate friend, the fact of her pregnancy; her delivery should not have been secret; she should have prepared for the birth—the living birth—of her infant; there should be no marks of wilful violence on the body: in short, it is easy to judge from the history of any given case, whether the accused *wished* the life or death of the child, and therefore whether it is likely she *would*, (even allowing that, with sufficient strength and self-possession at such a moment, she *could*) inflate the infant's lungs.

The idea has also been broached, that possibly inflation might have been practised by some malicious person, in order to trump up a charge of infanticide against the mother. Now there happens never to have been, as we trust there never will be, an instance of this kind of villainy. Only consider all that would be required to make it in any degree effective. The diabolical perpetrator of such a deed should have some medical and medico-legal knowledge; his interference, too, could hardly have been premeditated—at least it must

* Medical and Physical Journal, May 1833, p. 376.

be contingent on the infant being born dead. In this case, too, there should be no collusion, or semblance of guilt, about the mother; no secrecy, no feigning, nor dissembling: in fine, no violence on the body of the child; or should there be marks of violence, they should be such as were probably inflicted *after* death, not before it, as the infant is presumed to have been still-born; so that, on a little reflection, it must be seen how almost utterly impossible it would be to substantiate a plea of this kind, were it ever set up in a trial for infanticide.

(d.) *The infant might have breathed in the passage.*—It is beyond a doubt that an infant *may* breathe, and yet die, before it is wholly expelled from the mother; but if it be so vigorous as to commence respiration thus early, what may have caused its death before it was wholly born? Such cases are universally admitted to be rare, and when they do occur, to be owing to tedious delivery, or some physical obstacle on the part of the child, or the mother, in the way of malformation. If anything of this kind have caused the infant's death, it ought so to appear in evidence. Respiration in the passages may also take place, where the child is born by the feet, and the head is detained for some time; or where the hand is introduced to accelerate a tedious labour. But neither of these cases is likely to occur in the practice of legal medicine, for they imply the presence of medical or other assistance; at least the circumstances preclude the idea of concealment. The objection, therefore, of breathing before delivery, ought not to be admitted without some feasible ground. It is to be recollected, also, that the hydrostatic test, in shewing that the child *did* breathe, has performed its office: *when* it breathed, and *where*, must be made out by other evidence.

(B.) *Sinking of the Lungs.*

The sinking of the lungs, wholly and every part, proves that the infant never respired—provided the following doubts or objections cannot be plausibly urged.

Objections: (a.) *The lungs may be diseased.*—No doubt there are diseases which begin even in foetal life; and the lungs of an infant may be so studded with tubercles, or gorged with blood or other fluids, that even though respiration have partially begun, they sink when put in water. Or they may be affected with Jörg's *atelectasis*, as we shall hereafter see. But this state of things can scarcely lead into error; the eye of the pathologist can judge of the presence of disease; and, besides, if respiration have taken place, the lungs cannot be so complete a mass of disorga-

nization in a new-born infant, as that every part of them should sink. Cut these organs, then, in pieces, and observe whether they *all* sink: if they do, there can have been no respiration.

(b.) *The infant may have been too feeble to respire sufficiently to cause the lungs to float:* those organs sink because their air-cells have been only very partially expanded. Granted that they *may* sink in their totality or integrity, yet unless, upon dividing them into small pieces, every portion sinks, the efficiency of the hydrostatic test rests unimpaired. Both experiment and theory warrant the deduction that it is impossible the lungs, in whole and in part, should sink, if they once received air. There is, however, one case, and we believe only one, on record, in which the lungs, and every part of them, are said to have sunk—the subject being an infant known to have lived and breathed for a time. Dr. Bernt, of Vienna, relates the case. In a seven months' child, which lived *two hours*, the lungs, he says, were ten and a half grains heavier than their volume of water, and every fragment sank. But, with all due deference to the high authority on which this fact is stated, it may be doubted whether the experiment was carried sufficiently far to ascertain that every portion, however small, sank under the given circumstances. At all events, the most rigorous conclusion respecting the present objection can amount only to this—that here is a solitary instance in which the hydrostatic test does not show that air had been admitted into the lungs, even where respiration is known to have taken place.

Whenever the medical jurist finds himself in this difficulty—which confessedly will very rarely happen—he must only rest his decision on the application of the other tests—the colour, consistence, and volume of the lungs; their absolute weight as compared with that of the whole body; the condition of the vessels of the liver and heart; the state of the stomach, umbilicus, &c. From all these, with a proper regard to their relative and combined value, he will be able to derive a satisfactory conclusion.

(c.) *An infant may live for a short time without breathing.*—The English law distinctly recognizes this fact, though the Scotch does not. A child may be born in the membranes—or with a *caul*, as the vulgar designate it—and in that state it may be destroyed, yet the hydrostatic test give no evidence that it had survived birth. This is true: for the hydrostatic test only indicates that breathing *did*, or did not, take place; and, of course, in the circumstances in question, does not apply.

But neither do any of the other tests with which we are acquainted. The only means, therefore, by which this objection can be removed, is, by moral evidence of the fact that the infant never moved.

Such are the peculiarities of the hydrostatic test in its simple form, and such the precautions to be used in applying it.

Modifications of the Hydrostatic Test.

Two methods have been proposed, and one of them actually put in practice, whereby the common mode of observing the specific gravity of the lungs might be improved.

Daniel's test.—Daniel, in 1780, contrived a balance, one scale of which was suspended in a tin or sheet iron vessel, large enough to permit the free immersion of the organs of the chest. First, the lungs, heart, and thymus, were carefully removed from the body, tying the large blood vessels; they were weighed in the usual manner: the heart and thymus were then weighed separately—the difference of weight being that of the lungs. The lungs were then weighed in water (being caused to sink, if necessary, by an additional apparatus), so as to ascertain their loss of weight in that fluid, which of course depended on their volume,—the loss of weight on hydrostatic principles being equal to that of the bulk of water displaced. Hence, for example, lungs equivalent in volume would lose equal weights, although the same lungs, before immersion, might have been to each other as 2 to 1. In this case the probability would be that the lungs weighing 1 in air were artificially inflated.

The design of Herr Daniel was to distinguish, if possible, between the effects of respiration, and those of artificial inflation. But the utmost that could be gained by the practical use of his method, would be the formation of tables, whereby certain averages might be determined for resolving doubtful questions concerning respiration. No such tables have ever been constructed; and even if they had been, it is extremely questionable how far they would prove satisfactory.

Bernt's test.—Prof. Bernt, of Vienna, some years ago, devised another plan for perfecting the hydrostatic test. He took a glass jar, a foot in height, and three and a half in diameter. Two pints of distilled water were introduced into the vessel, and the level of the fluid was marked accurately and permanently on the glass. Three double columns were then drawn in the same manner vertically on the vessel; each for male and female foetuses of seven months, eight months, and nine months. The lungs and hearts of foetuses of these

ages were then procured, under circumstances exactly known as to their having never respired, imperfectly respired, or respired perfectly. By the careful immersion of the organs of the chest, in each case, a scale in the respective columns was formed, which was to serve as a standard of comparison for the lungs and hearts of other foetuses, the history of which might be unknown, but the fact of whose respiration might be hereby determined.

Several objections have been made to the efficiency of this instrument, and even to its accuracy; inasmuch as it is founded on principles which are rather more theoretically than practically true. It will not be necessary for me here to enter into an examination of these points: suffice it to say, that while Bernt's method is perhaps more simple, and better suited to practical purposes, than Daniel's, it is still very far from being so free from faults (independently of the difficulty of procuring the required vessel), as to render it likely ever to be adopted by medical jurists in this country. Even in Germany it has never, I believe, been more than once employed in a court of justice; and in France it seems to have met with no reception.

Proofs of Respiration from the Circulatory Apparatus.

When an infant has begun to breathe, certain changes immediately take place in the organs provided for the circulation of the blood. A change, for example, occurs in the shape and size of the arterial duct, in the position of the foramen ovale, and in the venous canal. Each of these shall be noticed separately; but first let us refer for a moment to the locality of the principal parts concerned; they are represented in the following figure of the peculiarities of the *fœtus*:—

Blood is supplied from the placenta (supposed to be on the left hand side of the page), through the umbilical vein (*r*), to the liver (*b, c*), heart (*a*), and thence to the whole of the body of the foetus. The vein, just mentioned, having sent several branches into the liver, communicates directly with the ascending cava (*p*), by the vessel (*s*) which is peculiar to the foetus, and is named the *venous canal*. The blood, upon reaching the right ventricle of the heart, is thence propelled into the pulmonary artery (*k*). Now, previous to the commencement of the respiratory process—during uterine life, for example—a very small portion of blood is sent to the lungs by the right and left branches of the artery last mentioned—perhaps no more than they passively, and in their collapsed state, admit; but the great mass of it is

FIG. 27.—*Peculiarities of the Fetus.*

thrown directly into the aorta, through the medium of the *arterial duct* (*l*). Respiration, however, having once begun, a material alteration is observed to take place in this latter vessel; and this we now proceed to notice.

State of the arterial duct: the Vienna test.
—The arterial duct (*m*, fig. 28) is about

FIG. 28.

The fetal heart, with the auricles removed so as to display the roots of the pulmonary artery (*g*) and the aorta (*d*). The arterial duct (*m*) is separated a little from the aorta, leaving the space (*a*) between them.

half an inch in length, and its calibre nearly equal to that of the pulmonary artery.

Now, according to Dr. Bernt, breathing has no sooner begun than the shape of the duct alters; from being cylindrical it becomes conical; the aperture by which it enters the aorta at (*n*) becoming contracted and oval. This happens, says Dr. Bernt, even in the course of a few moments. If the child has breathed for some hours, or days, the duct is found once more cylindrical, but much contracted, and shorter; so that it is now, perhaps, not longer than one of the pulmonary branches. After respiration for a week, the arterial duct is dwindled to the size of a crow-quill, having been, before breathing commenced, fully as large as a goose-quill.

If these changes invariably took place at the epochs, and after the manner, described by the Vienna professor, they would constitute an invaluable test—as was, indeed, at first, most sanguinely expected. In any case of disputed respiration, it would then have been only necessary to lay bare the great vessels at the summit of the heart, and compare the arterial duct with the pulmonary artery in shape and size. But, unfortunately, though the fact of the occurrence of these changes is unquestionable, they are not found to proceed with that order and regularity, much less with that rapidity, in the first instance, pointed out by Bernt. Even his own cases, related in the tract in which the nature of the test is

described, furnish sufficient evidence of its precariousness. Other observers, too, have failed in finding it correct: so that at present the test of Bernt, or the *Vienna test*, as it has been called, is only considered as a secondary one,—one, however, which ought never to be overlooked in investigating the question of live or still birth; for however inexact it may be in enabling us to state the length of time during which an infant breathed, it has considerable weight in serving to determine, in conjunction with other tests, whether the infant ever respired or not.

Foramen ovale.—The state of the foramen ovale may also serve in some degree to show whether foetal life had ceased, and extra-uterine, by respiration, had begun. The situation of this aperture, between the right and left auricle of the foetal heart, is represented in the subjoined figure.

FIG. 30.

Another view of the right auricle, laid open to display the foramen ovale. This figure, and figure 28, are taken from sketches by Dr. J. Beck.

FIG. 29.

The foetal heart, suspended by the superior vena. The interior of the right ventricle (*d*) and auricle (*a*) displayed; *c* is the valve, and *b* the foramen ovale.

Through this opening (*b*) a portion of the blood from the right side of the heart is sent to the left side, without being previously circulated through the lungs. In some infants it becomes closed as early as the first day after birth; but this is not very usual: more frequently several days elapse, and in certain instances even years, without its closing. For medico-legal purposes, therefore, the fact of the closure of the foramen ovale can be of little or no value; but there is another fact connected with the same opening, which is rather better deserving of notice. The position of the foramen on the valve (*c*) is said to change

gradually after birth. It is originally situated in the centre; but as soon as respiration begins, it is on the right side, whence it subsequently proceeds, from below upwards, towards the left side; thus revolving, as it were, round the right edge of the valve. It must be confessed, however, that the ascertainment and appreciation of these facts require a degree of anatomical dexterity not commonly met with among practitioners,—which must be a bar to the practical utility of the test, even though it were better recommended to us than it is by the experience of good observers; for such have not always found the reality to correspond with the doctrinal statement.

Venous canal.—This vessel (*s*, fig. 27) is rarely found impervious before the fifth day after birth, and its changes consequent on respiration occur so slowly, as to be scarcely, if at all, available for the purposes of the medical jurist. It must be recollected, that the question in reference to infanticide generally, is, whether the infant was still born, or lived a few moments or hours. Now the process of obliteration does not begin to be observable in the venous canal till about the second or third day.

The Liver.—It has been attempted to found upon the changes undergone by the liver in consequence of respiration, another test for ascertaining whether an infant ever respired or not. The liver, during foetal life, is known to be an important organ; it is comparatively larger and heavier at this period than it is afterwards; it forms a large reservoir for the blood, where perhaps some important alterations are effected in this fluid before it

is sent on to the heart. Now, when the lungs are expanded by respiration, they receive a large quantity of the circulating blood, and it is generally supposed that in this way they take upon them, in some measure, certain functions which the liver had previously performed: at all events, the latter organ is found, in most cases, to be more contracted in size, and less loaded with blood, than it usually is anterior to birth. Hence it was suggested that probably a static liver-test, on the principle of Ploucquet's lung-test, might be contrived—by determining the ratio of the weight of the liver to that of the whole body. According to Henke (*Abhandlungen*, Band 5.), this suggestion was first made by Autenrieth, of Tübingen, in 1806; and afterwards, in America, by Dr. John Beck.

The Medical Faculty of Tübingen actually proposed it as a prize question, a few years since, to ascertain whether there was not a constant ratio between the weight of the liver, before and after death, and that of the body. Some very valuable dissertations were the result. But the conclu-

sions were unfavourable to the establishing of a liver-test. And such a test, obviously, were it possible to establish one, must always be secondary and subordinate to the lung-test; for not only is the lessening of the absolute weight of the liver dependent on the increase of that of the lungs, but the alteration can never be so strongly marked in the liver as in the lungs; the latter bearing originally so small a proportion to the weight of the body, and not being, on an average, above a third part of the weight of the liver. It has already been shown that the static lung-test is sufficiently precarious; but from a few examples it will readily be understood that a static liver-test, were there one, must be infinitely more so: for it appears to be materially modified by the kind of death which the infant suffers, and to have some special relation to the size and condition of the placenta.

Dr. Koch, of Hamburg, author of one of the Tübingen prize dissertations*, supplies us with the following facts:—

	Liver to body.	Lungs to body.	Lungs to liver.
Still-born, heavy and large child, labour } very difficult	1 : 13	1 : 57	1 : 4
Died in birth—artificial labour	1 : 94	1 : 87	1 : 1
Born dead, child large, pelvis deformed, su- } gillations	1 : 40	1 : 80	1 : 2

These cases, Dr. Koch confesses, were the most striking and remarkable among the 79 (26 still-born and 53 live-born) which he examined; but then it appears that

of the entire number no more than 17 approached to what is commonly allowed to be about the average standard, namely—

	Liver to body.	Lungs to body.	Lungs to liver.
In the still-born	1 : 22	1 : 65	1 : 3
In the live-born	1 : 25	1 : 30	1 : 1

From these circumstances we may fairly conclude that no liver-test, exact enough for medico-legal purposes, has hitherto been, or is likely soon to be, established. Yet, though our observations on the state of the liver may not of themselves warrant us in forming a reasonable presumption for or against the fact of respiration, they should by no means, in inquiries of such vital interest as those relating to infanticide, be neglected; for the inference they would authorize, however slight in itself, might have much force, taken in conjunction with other deductions from

other premises. In short, that rule applies here, which can scarcely be too frequently repeated, that the medical jurist, in his researches connected with the serious charge of infanticide, must never rely solely upon any one test, or particular mode of proof, but observe how far this corresponds in its evidence with the other tests, for in the multitude of these, consentient and combining, there is safety.

* Dis. inaug. medico-forensis, &c. Tubing. 1831.

LECTURES

ON

MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, Esq., F.L.S.

LECTURE LVII.

ANOTHER and an important umbelliferous plant is the

Conium maculatum.

History.—This plant is usually supposed to be the *κόνειον* of the Greek writers, the celebrated *Athenian state poison*, by which Socrates and Phocion died, and the *cicuta* of the Roman authors. Various reasons contribute to give the common opinion on this point a high degree of probability. Dioscorides described the plant sufficiently well to prove it must have been one of the Umbelliferae; and he tells us it had a heavy odour, and a fruit like that of anise. The latter simile applies to our Conium, for a very intelligent druggist mistook, in my presence, the fruit of the hemlock for that of anise. Dioscorides also tells us that the *κόνειον* of Crete and Megara was the most powerful, and next to this came that of Attica, Chio, and Cilicia. Now Dr. Sibthorp found Conium maculatum growing near Constantinople, not unfrequently in the Peloponnesus, and most abundantly between Athens and Megara. So that the locality of our Conium agrees, as far as has been ascertained, with that of the ancient plant. We may gather from the poetical account of the effects of *κόνειον* given by Nicander, that this plant “brings on obliteration of the mental faculties, dimness of sight, giddiness, staggering, stifling, coldness of the limbs, and death by asphyxia; a view of its effects,” says Dr. Christison, “which differs little from the modern notions of the poisonous action of the spotted hemlock.” It is also remarkable that the ancients regarded *κόνειον* as having the power of dissolving tumors—a virtue which has been assigned to hemlock by writers of the present day.

I am fully aware that the characters of the ancient plant, as given us by Dioscorides and Pliny, are insufficient to distinguish it from some other Umbelliferae, yet I think the evidence of its being our Conium maculatum is deserving of much greater confidence than Dr. Christison

is disposed to give it. The absence of all notice, in the writings of the ancients, of the purple spots on the stem, has been urged against the probability of this opinion. “Pliny’s term *nigricans*, applied to the stem, is but a feeble approach,” says Dr. Christison, “to the very remarkable character of the modern plant, the purple spotted stem.” It is somewhat remarkable, however, that a celebrated modern writer has employed a very analogous term in describing the hemlock plant. In Mr. Waller’s translation of Orfila’s Toxicology, the inferior parts of the stem of Conium maculatum are said to be covered “with spots of a brown purple, or *blackish*,” so that Pliny is not alone in his erroneous account of the colour of the stem.

One fact strongly in favour of the identity of the ancient and modern Conium is, that there are no other poisonous Umbelliferae growing in Greece, to which the description of Dioscorides and Pliny could apply, than our Conium: at least none others were found by Dr. Sibthorp, otherwise he would have noticed them in his “*Prodomus Flora Græcæ*.” Thus we may infer that the *Cicuta virosa* (which, according to both Haller and Dr. Christison, “comes nearer the ancient description than any other” of the poisonous Umbelliferae); the *Ænantha crocata*, *Æthusa Cynapium*, *Chærophyllum temulentum*, and *Phellandrium aquaticum*, are not natives of Greece. Now this fact taken in conjunction with another—namely, that Conium maculatum grows in the very spot indicated by Dioscorides, is strongly in favour of the identity of this plant with the *κόνειον* of the Greeks.

Etymology.—It is evident that our generic term Conium is derived from the Greek word *κόνειον*. Linnæus has been censured by Lamarck for using this name, since the Latin authors call our hemlock *Cicuta*, which he, therefore, contends ought to be its designation now. But it ought to be recollected that Linnæus has only restored its ancient name, for the word *Cicuta* is unknown in the Greek language. By modern botanists the term *Cicuta* is applied to a distinct genus of plants, and when, therefore, we meet with it in botanical works, we must not confound it with the *Cicuta* of the Romans.

Botanical characters.—Conium maculatum is an indigenous plant, frequently found growing in waste places, banks, and under walls, flowering usually in June and July. Its root is biennial, fusiform, whitish, and from six to twelve inches long, having some resemblance to a young parsnip. The stem is from two to six feet high, round, smooth, shining, hollow, and

spotted with purple. The leaves are tripinnate, with lanceolate pinnatifid leaflets, of a dark and shining green colour, smooth, very foetid when bruised, with long, furrowed footstalks, sheathing at their base. The umbels are many rayed, furnished with a general involucre of several (usually from three to seven) lanceolate leaves, which are membranous at their edges: the partial involucre is composed of three leaves on one side. The calyx is obsolete: the corolla consists of five white obcordate petals, inflexed at the points: the stamina are five, epigynous, and as long as the corolla: the ovarium is ovate, two-celled, striated: there are two filiform spreading styles, each furnished with a round stigma. The fruit is ovate, and compressed laterally: each of its mericarps, or carpels, has five primary (but no secondary) ridges, which are undulato-crenated: the channels have many striæ, but no vittæ. The seed has a deep hollow groove in front.

In distinguishing hemlock from other Umbelliferae, the following characters should be especially attended to; the large, round, smooth, spotted stalk—the smooth, dark, and shining green colour of the lower leaves—the disagreeable smell when bruised (compared by some to that of mice, by some to fresh cantharides, by others to that of cat's urine)—the general involucre usually of from three to seven leaves—and the partial involucre of three leaves.

The indigenous Umbelliferae most likely to be confounded with *Conium maculatum* are *Oethusa Cynapium*, or fool's parsley, and *Anthriscus vulgaris*, or common beaked parsley.

Oethusa Cynapium is distinguished from hemlock by its smaller size, by the absence of the strong disagreeable smell of the leaves, by the non-existence of spots on the stem, by the want of a general involucre, and by three long, narrow, unilateral drooping leaves composing the partial involucre.

Anthriscus vulgaris is distinguished by the lighter colour, and slight hairiness of the leaves, by the absence of spots on the stem, by the swelling under each joint, by the absence of a general involucre, by the roughness of the fruit, and by want of the strong unpleasant odour when the leaves are bruised.

Chemical composition.—Schrader, of Berlin, has published a comparative analysis of wild and cultivated hemlock, but with no important results. He tells us that the juice of hemlock has a striking resemblance to that of our common cabbage; and he gives the following as the constituents of the two.

	Hemlock.	Cabbage.
Extractive	27.3	29.4
Gummy extract	35.2	20.9
Resin	1.5	0.5
Vegetable albumen.....	3.1	2.9
Green fecula	8.0	0.5
Water, with acetic acid, sulphates, chlorides, nitrates, and phosphates of potash, lime, magnesia, iron, and manganese	924.9	935.0
	1000.0	1000.0

It will be evident from this analysis that Schrader did not succeed in isolating the active principle of the plant.

Peschier has asserted the existence of a new organic salt in hemlock, which might be termed *coniate of conia*, since he says it consists of a peculiar acid, which he calls *coniic acid*, and an alkali. His statements, however, require confirmation.

Brandes also analysed hemlock, and gives as its constituents—

A peculiar basic substance (*conicine*).
Very odorous oil.
Vegetable albumen.
Resin.
Colouring matter.
Various salts.

In 1827, Giseke obtained the active principle of hemlock (*conia*) in combination with sulphuric acid, and made various experiments with it. In 1831, Geiger procured the *conia*, for the first time, in an isolated form, and described some of its properties and effects on animals. It has subsequently been more fully investigated by Dr. Christison, and by MM. Boutranchard and O. Henry. Let us pass in review some of the principal constituents of hemlock.

1. *Odorous principle.*—The activity of hemlock does not depend on its odorous principle, for the distilled water of hemlock, which possesses in a high degree the odour of the plant, is scarcely, if at all, poisonous. The odorous principle is volatile oil.

2. *Conia.*—This alkali, which has also been termed *cicutine*, *conicine*, and *conicine*, was, as I have already mentioned, first obtained in the isolated state by Geiger in 1831. Its properties were carefully examined by Dr. Christison in 1836. In 1834, Deschamps, an apothecary at Avignon, asserted that the *conia* of Geiger owed its alkaline properties to ammonia, and that the odorous principle which accompanied the ammonia could not saturate acids. His assertions, however, have

been completely disproved by MM. Bou-
tran-Charlard and O. Henry, during the
last year (1836).

Conia has been found in the leaves and
fruit, and probably exists in all parts of
the plant. Dr. Christison obtained 2½
ounces of hydrated conia from 40 lbs. of
the green seeds (mericarps). The leaves
contain a less quantity than the fruit.

Conia exists in hemlock as a salt,—that
is, in combination with an acid. Hence
the use of the alkali (soda, potash, or
lime) employed in the process is to ab-
stract the acid, and thereby to set free
the conia. It is uncertain what acid is
combined with the conia: Peschier, as
already related, says it is a peculiar
organic acid (*coniic acid*), crystallizable in
six-sided prisms, insoluble in æther and
alcohol, and capable of decomposing the
calcareous and barytic salts.

Preparation.—One method of preparing
conia, and which yielded Dr. Christison
the largest product, is to distil the alco-
holic extract of the seeds (mericarps) with
its own weight of water and a little
caustic potash.

MM. Boutran-Charlard and O. Henry
have procured it by another process with-
out the use of alkalies.

Properties.—When pure, conia is an
oily-looking transparent liquid, lighter
than water. Its odour is strong and pene-
trating, and is said to be like that of hem-
lock, of tobacco, and of mice, combined: its
taste is acrid. It is sparingly soluble in
water, but is entirely soluble in alcohol
and æther. It reddens turmeric, and
neutralizes the dilute acids, forming salts.
While saturating, the liquors have a bluish-
green tint, which subsequently passes to a
reddish-brown. It combines with about a
fourth of its weight of water to form
a *hydrate of conia*. When placed in a
vacuum, in the presence of bodies very
attractive of water, it in part volatilizes,
and leaves a reddish, very acrid, pitchy
residue, which appears to be anhydrous
conia. The vapour of conia is inflamma-
ble. By exposure to the air, it acquires a
dark colour, and is resolved into resin and
ammonia. Its boiling point is 370° F.,
but it readily distils with water at 212° F.

Composition.—According to Liebig, it
consists of—

Carbon	66.91
Hydrogen	12.0
Oxygen	8.28
Nitrogen	12.8
<hr/>	
99.99	

These numbers nearly correspond to—

11 atoms carbon	66
12 atoms hydrogen	12
1 atom oxygen	8
1 atom nitrogen	14
<hr/>	
100	

But until its saturating powers be ascer-
tained, its atomic weight cannot be deter-
mined with accuracy.

Characteristics.—That it is an alkali, is
shewn by its action on turmeric paper,
and by its neutralizing acids. Like am-
monia, its vapour produces white fumes
with the vapour of hydrochloric acid. It
agrees with the other organic alkalies in
producing a copious white precipitate
(tannate of conia) with infusion of galls.
From ammonia it is distinguished by its
odour and inflammability, and by the
solubility in alcohol and deliquescent cha-
racter of its sulphate. From the other
vegetable alkalies it is distinguished by its
liquidity at ordinary temperatures, by its
volatility, and by its odour. It is not red-
dened by either nitric or iodic acids.

Salts of conia.—Several of the salts of
conia are crystallizable: they are deli-
quescent and soluble in alcohol. When
we evaporate solutions of these salts with
a gentle heat, they lose, like the ammonia-
cal salts, a part of their base, the odour of
which may be readily recognized. The
nitrate of conia, when decomposed by
heat, yields brown pyrogenous products.
If potash be added to an inodorous salt of
conia (as the sulphate), the conia is imme-
diately set free, and may be recognized by
its odour.

Effects of conia.—*On animals.*—The effects
of conia have been tried on various ani-
mals, namely—

- Mammalia*, as the dog, cat, rabbit, and mouse.
- Aves*, as the pigeon, kite, and sparrow.
- Reptilia*, as the slow worm.
- Amphibia*, as the frog.
- Annelida*, as the earth worm.
- Insecta*, as the fly and flea.

One drop placed in the eye of a rabbit
killed it in nine minutes; three drops used
in the same way killed a strong cat in a
minute and a half; five drops poured into
the throat of a small dog began to act in
thirty seconds, and in as many more
motion and respiration had entirely ceased.

The following are the symptoms pro-
duced, as detailed by Dr. Christison. “It
is, in the first place, a local irritant. It
has an acrid taste; when dropped into the
eye, or on the peritoneum, it causes red-
ness or vascularity; and to whatever texture
or part it is applied, expressions of pain
are immediately excited. But these local
effects are soon overwhelmed by the in-

direct or remote action which speedily follows. This consists essentially of swiftly-spreading palsy of the muscles,—affecting first those of voluntary motion, then the respiratory muscles of the chest and abdomen, lastly the diaphragm, and thus ending in death by asphyxia.” Convulsive tremors, and twitches of the limbs sometimes, though not invariably, are observed. The external senses do not appear to be affected until respiration is impaired. If a rabbit be lifted up by his ears when under the influence of the poison, he makes the same kind of struggles to be released that he does when in health. So also if we place him in an uneasy posture, he makes attempts to alter his position, proving that his senses are unimpaired. After death the muscles are susceptible of the galvanic influence. MM. Boutran-Charlard and O. Henry state that most of the animals to whom they gave conia became “a prey to the most dreadful convulsions. The plaintive cries, the contortions, and the rigidity of the limbs, which have always preceded death, leave no doubt as to the cruel pains which this kind of poisoning brings on.” This account agrees neither with my own observations, nor with those published by Dr. Christison.

Does conia become absorbed? In favour of the affirmative view of this question may be mentioned the fact, that this alkali acts on all the textures admitting of absorption; and that the quickness with which the effects occur are in proportion to the absorbing power of the part. But the rapidity of its action when introduced into the veins is a barrier to the supposition of its acting on the nervous centres by local contact; for Dr. Christison states, that two drops neutralized by dilute muriatic acid, and injected into the femoral vein of a young dog, killed the animal in two or three seconds at farthest.

The primary seat of the action of conia is probably the spinal cord. In this conia and strychnia agree; but in the nature of the effect, they seem, as Dr. Christison has observed, to be the counter-parts of each other. Conia exhausts the nervous energy of the cord, and causes muscular paralysis; strychnia irritates it, and produces permanent spasm of the muscles. Both kill by bringing on asphyxia, the first by the paralysis, the second by the spasm, of the respiratory muscles.

Antidote.—At present we know no antidote to this poison. Probably the infusion of galls would be the best remedial agent, since the tannic acid contained in it precipitates the conia. To prevent the asphyxia, artificial respiration should be performed. Might not strychnia be em-

ployed with advantage, since it appears to produce a condition of the spinal cord opposite to that of conia.

Uses.—The known effects of conia would suggest its employment in tetanus, and in poisoning by strychnia and brucia, or by substances containing these alkalies.

3. *Green fecula.*—This constituent of hemlock is not distinguishable from the green fecula of other plants.

4. *Vegetable albumen.*—This also is like the albumen of other plants.

5. *Extractive matter.*—This is brown, and soluble in water. It attracts oxygen slowly from the atmosphere, has a peculiar hemlock odour, and a bitter taste. Its ashes contain carbonate of lime, with traces of carbonate of magnesia, sulphate of potash, and chloride of potassium.

6. *Resin.*—This is soft, yellowish brown, and somewhat acrid.

Physiological effects.—(a). *On vegetables.* Marcet placed a haricot plant (*Phaseolus vulgaris*) in a solution of five grains of the extract of hemlock. In a few minutes the two lower leaves curled at their extremities; the next day they were yellow, and subsequently died.

(b). *On animals generally.* The effects of hemlock on animals have been tried by Harder, Wepfer, Orfila, and Schubarth. The animals experimented on were the dog, wolf, rabbit, and guinea-pig. From the observations of Orfila, hemlock is a local irritant (though this action was not constantly observed), and produces giddiness, convulsions, loss of sensibility, palsy, and coma. This account, as Dr. Christison observes, does not agree with the symptoms induced by conia, which does not seem to affect the senses so long as the respiration goes on. “But it is possible,” he adds, “that the difference is more apparent than real, and that hemlock has been supposed to extinguish sensation, merely because, by inducing paralysis, it takes away the power of expression; at least, in some experiments I have made, sensation did not appear to be affected; and the whole phenomena were identical with those produced by conia. In these experiments I used very strong extracts, prepared by absolute alcohol from the fresh leaves or the full-grown seeds; and each of them occasioned, in doses of thirty grains or thereabouts, paralysis of the voluntary muscles, with occasional slight convulsions, then paralysis of the respiratory muscles of the chest and abdomen, and finally cessation of the action of the diaphragm: sensation appeared to continue so long as it was practicable to make an observation on the subject; and the heart contracted vigorously for a long time after death.”

(c.) *On man.*—In small or medicinal doses, hemlock has been frequently administered for a considerable period, with obvious relief, in certain diseases (tumors of various kinds, for example), without any other evident effect: hence the statement of some authors, that hemlock acts insensibly on the system. "It seldom purges (says Storck), "and very rarely vomits. Sometimes it increases perspiration, and often it occasions a copious discharge of viscid urine. In many patients, nevertheless, it does not sensibly augment any of the excretions." Long-continued use, especially if the doses be increased, will sometimes occasion disorder of the digestive organs or of the nervous system, dryness of the throat, thirst, and occasionally, it is said, an eruption on the skin. Choquet mentions the case of a man who gradually increased the dose of the extract to half a drachm: it produced slight delirium and syncope, which obliged him to suspend its use.

In large or poisonous doses, the symptoms are those indicating disorder of the cerebro-spinal functions. In some of the best recorded cases the leading symptom was coma; the effects being altogether analogous to those of opium. In other instances, convulsions, or violent delirium, or both, were the prominent symptoms. As an illustration of the comatose condition sometimes brought on by this poison, I shall quote a case recorded by M. Haaf, a French army surgeon, and which occurred to him while in garrison at Torrequemada, in Spain, in March 1812:—

A soldier having eaten of some broth, into which hemlock had been put, went to sleep immediately after his supper. In an hour and a half he was found groaning and breathing with difficulty; in consequence of which M. Haaf was sent for. He found his patient in a profound sleep, without sense, respiring with extreme difficulty, and lying on the ground. His pulse was 30, small, and hard; the extremities cold; the face bluish, and distended with blood, like that of a person strangled. Twelve grains of emetic tartar were given, and occasioned some fruitless attempts to vomit. He became gradually worse, had violent palpitations of the heart, and died in three hours after his fatal supper.

Several other cases in which coma was the leading symptom might be quoted, but the one just related is the best.

We have no well-detailed cases in which delirium was the leading symptom. The following must suffice, by way of illustration; it is from Kircher. Two priests ate hemlock root by mistake: they became raving mad, and mistaking themselves for

geese plunged into the water. For three years they suffered with partial palsy and violent pain.

As illustrations of the convulsions caused by hemlock, I may refer to the cases mentioned by Limpricht and Ehrhard. The first states that an old woman suffered for three months with abdominal pain and convulsive movements of the limbs, in consequence of eating hemlock root. Ehrhard mentions trismus as one of the symptoms in another case. Dr. Watson has related two cases in which giddiness, coma, and convulsions occurred.

Uses.—The following are some of the cases in which hemlock has been employed:—

1. *In cancer and scirrhus.*—The ancients seem to have been of opinion that hemlock exercised a specific influence over the breasts and testicles. "It extinguishes the milk," says Dioscorides, "and prevents the development of the mammae of virgins: moreover, in boys it causes wasting of the testicles." Pliny gives a similar account of it, and adds, "it reduces all tumors." The same notions of its effects seem to have been entertained by the Arabians, for Avicenna praises it as a remedy for tumors of the breasts and testicles.

At the head of modern authors who have written on hemlock, stands the renowned Baron Storck, physician to the Pazmarian Hospital, at Vienna; who, in 1761, published the first of his essays on the medicinal uses of hemlock in various diseases, but more especially in cancerous and scirrhus affections. Of these essays very exaggerated accounts are frequently found in pharmacological works. Storck is represented by some as declaring hemlock a remedy capable of curing every cancer, and the charge is repeated in a recently published work: but surely the authors cannot have read his essays. In his second work, he says, "Many misunderstood my opinion of hemlock, from my first essay; as they thought that I had offered a remedy which I believed to be universal and sufficient, when given alone, in all cases. But I by no means meant so." In his Supplement, Storck desires "that no physician whatever may imagine that it is my opinion these disorders must in general, and every where, be cured by hemlock. I say, and acknowledge openly, that I have also had patients in every kind of them who have received no benefit from it; though, from the similitude of the disease, the use of it was indicated." The most candid and fair criticism of Storck's essays will be found in the *Materia Medica* of Dr. Cullen; and I quite agree with the opinion therein expressed, that

Storck "has represented the virtues of hemlock as much greater than ever they were, or ever will be found to be."

Storck, however, is not the only modern writer who has asserted that cancer and scirrhus were sometimes cured, at other times ameliorated, by hemlock. Cases illustrative of its beneficial effects were published by Marteau, in 1761; by Decotes, jun. in 1762; by Ehrhard, in 1763; by Larranture, and by Hoffmann, in 1764; by Ranard, in 1765; by Masars de Casselles, in 1770; by Lemoine, in 1772; by Collin, in 1779; by Buissonal, in 1787; and, much more recently, by Recamier. Bayle, in his "*Travail Thérapeutiques*," has collected accounts of no less than forty-six cases of cancerous diseases, said to have been cured by hemlock, while twenty-eight were ameliorated. With this evidence before us, we can hardly refuse to admit that in diseases reputed cancerous, hemlock has, on several occasions, been beneficial. But it is also not the less true, that in the hands of a large majority of practitioners it has completely failed; and I believe that at the present day no surgeon has any confidence in it as a curative means, though he may occasionally employ it as a palliative—that is, to alleviate pain. Whether the failures ought, in part, at least, to be ascribed to imperfect modes of preparing this plant, we are as yet unable positively to affirm. One fact, however, is quite certain—that the preparations of hemlock in ordinary use, are in nine cases out of ten inert, or nearly so. The remark made by Dr. Christison, with respect to the physiological effects of this plant, applies well to the point under discussion. "If," says this writer, "physicians or physiologists would acquire definite information as to the physiological effects of hemlock, in small or medicinal doses, they must begin the inquiry anew. Little importance can be attached to any thing already done in this field, as I have no doubt whatever, that by far the greater proportion of the preparations of hemlock hitherto employed have been of very little energy, and, in the doses commonly used, are absolutely inert."

2. *Scrofula*.—Another disease in which hemlock has gained considerable celebrity is scrofula, in consequence of the favourable reports of Storck, Marteau, Dupuy de la Porcherie, Lemoine, Collin, Hufeland, Fothergill, and others. It is a remedy, however, which is far from being universally, or even generally, efficacious. It is best adapted for persons of an irritable constitution, and is employed to improve the discharge, and to heal scrofulous ulcers, and to diminish the size of enlarged absorb-

ent glands. It is objectionable where active inflammation is going on, as well as when the digestive functions are much disordered.

3. *In visceral enlargements*, which are neither scrofulous nor carcinomatous, hemlock has been employed with occasional advantage. Thus in enlarged liver it has been used.

4. *In hooping cough*. In 1781, we are told, there reigned at Warsaw an epidemic of this disease: it was very obstinate, and resisted all the usual means of relief. Dr. Schlessinger obtained very beneficial results from the combined use of tartar emetic and extract of hemlock. In this country hemlock has been strongly recommended in hooping-cough by Dr. Butler: he says, it has an advantage over opium in not being so liable to check expectoration. The violent and periodical fits of coughing in this disease being apparently of a spasmodic nature, we can readily believe they may be relieved by hemlock, as well as by some other narcotics; but experience has fully proved that the disease is one which will run through a certain course independent of, or at least very little influenced by, hemlock or any other remedial means.

5. *As an anodyne*. The relief sometimes experienced in troublesome coughs by the use of hemlock is best referrible to the diminished sensibility of the bronchial membrane to the influence of the cold air. In various painful diseases, as coma, scirrhus, rheumatism, and neuralgia, hemlock is occasionally serviceable as an anodyne.

6. *In syphilis*. Storck, Collin, and others, have related cases illustrative of the beneficial effects of hemlock in syphilis. It is sometimes useful in alleviating nocturnal pains, and in diminishing the disposition to spread of irritable sores: beyond this it hardly deserves notice as a remedy for syphilis. I must refer to Mr. Pearson's "*Observations on the effects of various articles of the Materia Medica*" for some illustrative cases of its useful effects.

There are various other diseases in which hemlock has been recommended. I may mention only chronic diseases of the skin, dropsies, satyriasis, and nymphomania. Aretæus supposed hemlock had the power of extinguishing the venereal feelings, and St. Jerome tells us that the Ægyptian priests rendered themselves impotent by taking daily a little hemlock: hence the proposed use of it in satyriasis and nymphomania. Its effects in this way have, however, been denied. Storck applied for information on this point to women whose husbands had used hemlock, and says, "they were all content on their

rt, and protested on their consciences at they had not found any diminution of their husbands' vigour." Both Bergius and Storck have mentioned cases in which hemlock restored the venereal feelings.

The following table is taken from Bayle's "*Travaux Therapeutique*:" it shows the results obtained in a number of diseases by the use of hemlock.

Diseases treated by Hemlock.	Number of Cases.	Cured.	Ame- liorated.	Un- successful.
1. Cancerous maladies	341	46	28	267
2. Scrofula	43	34	4	5
3. Tumors and obstructions	40	35	4	1
4. Ulcers neither scrofulous nor can- cerous	20	17	2	1
5. Syphilis	27	20	3	4
6. Tetters (Dartres)	11	11	0	0
7. Tineas (Teignes)	6	6	0	0
8. Pulmonary phthisis	6	5	1	0
9. Asthma	5	4	1	0
10. Leucorrhœa	5	4	0	1
11. Scorbutus	4	4	0	0
12. Cataract	6	3	0	3
13. Hemeralopia	3	3	0	0
14. Amaurosis	2	2	0	0
15. Dropsy	2	2	0	0
16. Amenorrhœa	2	2	0	0
17. Ophthalmia, called serous (scro- fulous?)	1	1	0	0
18. Epilepsy	3	1	0	2

Administration.—The usual mode of exhibiting hemlock internally is in the form of powder or extract. The powder is obtained from the leaves, and has, when carefully prepared, a very fine green color, and the peculiar odour of the plant. The finest samples which I have seen were obtained by Mr. Batley, of Fore-street. It could be preserved in well-corked bottles, in a dark cupboard, or in a bottle enveloped in dark coloured paper. It ought to be kept in the dark, and the odour of conia when treated with caustic potash, especially if heat be applied; and we ought not to use it if it has been kept beyond the year, as its virtues become much diminished or lost by aging. The dose of it is three or four grains twice or thrice daily, the quantity being gradually increased until some obvious effect on the system is produced.

The extract is prepared by the evaporation of the expressed juice. Most of what is secured in commerce is inert. "We were one day," says Orfila, "in the shop of an apothecary, who had several times

furnished us with the extract of hemlock, which we had administered to dogs to the dose of ten drachms, without producing any serious accident. We endeavoured to prove to him that the medicine was badly prepared; and, in order to convince him effectually, we swallowed, in the presence of several persons who happened to be in his shop, a drachm of this extract (seventy-two grains) dissolved in two drachms of water. We felt no effect from it, whilst twenty or thirty grains of the extract, well prepared, would have probably proved fatal to us. Let it be conceived now what advantage a person is likely to derive from such an extract, who takes one or two grains of it per day, or even thirty or forty, with the hope of getting rid of a scirrhus tumor, or of any other disease."

The extract of hemlock usually contains very little conia; this has been shewn by Geiger and by Christison, and has been verified by myself. From extract, pro-

cured from one of the most respectable drug houses in town, I was unable to procure any sensible quantity of this alkali. "From what has come under my own observation," says Dr. Christison, "the extracts of hemlock may become feeble, if not even inert, in one of two ways,—either by the heat being continued after the concentration has been carried to a certain extent, or by long keeping. On the one hand, I have always observed, that from the point at which the extract attains the consistence of thin syrup, ammonia begins to be given off in abundance, together with a modified odour of conia. And, on the other hand, I have found extracts, which were unquestionably well prepared at first, entirely destitute of conia in the course of a few years,—a remark which applies even to the superior extract prepared by Mr. Barry, of London, by evaporation *in vacuo*. The mode of ascertaining the presence of conia is simply to triturate the extract, or other preparation, with solution of potassa, upon which an odour of conia is given off."

The *tinctura conii* of the London Pharmacopœia is prepared by digesting the dried leaves with some bruised cardamoms in proof spirit. Its dose is half a drachm to a drachm. Geiger, however, observed that the dried leaves of hemlock do not contain conia, and therefore this, like the powder and extract, is an objectionable preparation.

One of the best pharmaceutical preparations of hemlock would probably be an *alcoholic tincture of the bruised ripe fruit*. Dr. Christison says he procured from two hundred and twenty grains of the alcoholic extract of the ripe seeds (mericarps) upwards of five grains of colourless hydrate of conia.

A *poultice of hemlock* is sometimes employed as a soothing anodyne application to cancerous, scrofulous, and venereal ulcers. There are several modes of making it. The directions of the London College are, to mix two ounces of the extract of hemlock with a pint of water, and then add as much linseed meal as will make a poultice. The Dublin College direct it to be made by adding the powdered leaves to the strained decoction of the dried leaves. Some prepare it with the unstrained decoction and linseed meal; and occasionally the bruised leaves are used as a poultice.

The *ointment of hemlock* is ordered to be prepared, in the Dublin Pharmacopœia, by boiling the fresh leaves of hemlock in prepared hog's lard. It is employed as an anodyne application to foul, painful, and cancerous sores, to glandular and scirrhus swellings, and to painful piles. An extemporaneous substitute may be prepared with lard and the extract of hemlock.

Antidotes.—No chemical antidote is known for hemlock, though it is not improbable that an infusion of galls might be serviceable, as mentioned for conia. The first object, therefore, is to evacuate the poison from the stomach; this is to be effected by the same means as directed for poisoning by opium. If the poison be suspected to have passed into the bowels, a purgative is to be administered, unless diarrhœa have come on. The subsequent treatment will depend on the symptoms: blood-letting is frequently required, to relieve the congested state of the cerebral vessels. Opium is generally prejudicial. Artificial respiration may be resorted to in extreme cases.

Recognition in medico-legal inquiries.—Hemlock can only be properly recognized by its botanical characters, already described: yet its remarkable odour may sometimes be of considerable assistance in recognizing the plant or its preparations; nor is the fact to be lost sight of, that potash developes a strong smell of conia. In some cases it might be possible to obtain some conia by distilling the alcoholic extract of the suspected substance with water and caustic potash.

MENISPERMACEÆ.

In this family there are several substances requiring notice: I shall commence with

Cocculus palmatus.

History.—Franciscus Redi, in 1685, is the first writer who mentions the root of this plant: he praises it as an alexipharmic or antidote for poisons. Cartheuser afterwards examined it: but Dr. Thomas Percival gave the best account of it in his Medical Essays, published in 1773. This root has been known by various names, such as *Calumba*, *Colombo*, *Calomba*, and *Colomba*. It was at first supposed to come from Colombo, a town of Ceylon, and from which it was said to derive its name. But it is now known to be the produce of Mozambique; and we are told its African name (from which our designation is derived) is *Kalumb*,—which the Portuguese spell *Kalumbo*, the *o* in their language being mute.

Botanical history.—The *Calumba* plant is dioecious, and grows naturally and in great abundance in the thick forests that cover the shores of Oïbo and Mosambique on the east coast of Africa, as well as inland for fifteen or twenty miles. Its root is perennial, and consists of several fasciculated, fusiform, fleshy tubers. Externally it is covered with a brown warty epidermis; internally it is of a deep yellow colour, odourless, and of a very bitter taste. The stems are annual, herbaceous,

and twining,—in the male plant being simple, in the female branching: at the lower part they are beset with long glandiferous hairs. The leaves are alternate, nearly orbicular, deeply cordate, from five to seven lobed, wavy on the margin, hairy on both sides, and supported by long, hairy footstalks. The flowers are small, and are arranged in racemes: those of the male plant consist of a calyx, composed of six ovate sepals, arranged in two rows or series, a corolla of six green petals, and six stamens. The female flowers consist of a calyx, composed of six sepals, a corolla of six petals, and three pistilla. The fruit is drupaceous.

FIG. 153.—*Cocculus palmatus*.

From the preceding description it is evident the plant belongs to the class *Diacia*, order *Hexandria*, in the Linnean arrangement.

Preparation.—The natives never cultivate

the plant, the spontaneous produce being sufficient. The root is dug up in March, cut in slices, strung on cords, and hung up to dry in the shade.

Physical properties.—Columba root is met with in flat circular or oval pieces, of from half an inch to three inches diameter, and from one to three or four lines thick. It occurs also in cylindrical pieces of from one to two inches long. The epidermis covering the sides of the pieces is of a yellowish-grey or brownish colour, smooth or irregularly rugous. The transversal surfaces are of a greenish or greyish-yellow colour, depressed in the middle from the great shrinking of the medulla in the drying process, and consist of three or four concentric layers. The outer or cortical portion varies in thickness, but is usually about two or three lines thick. It is separated from the ligneous portion by a dark-coloured layer, not exceeding a hair in thickness. The internal or medullary portion is light, spongy, and shrunk. The radiating lines observed on the transversal surfaces offer some resemblance to those of the root of *Cissampelos Pareira*. The odour of Calumba is faint, but somewhat aromatic: the taste aromatic, and very bitter. In the larger and thicker pieces small holes are occasionally observed, which have been made for the convenience of drying.

Chemical composition.—The chemical properties of Calumba root were first examined by Cartheuser, afterwards by Josse and Percival; and in later times by Pfaff, Planche, Buchner, and Wittstock.

The following are the constituents of the root, according to two chemists:—

	Planche.	Buchner.
Bitter matter.....	13	10 to 12
Animal matter, soluble in water and } not in alcohol.....	6	0
Yellow resinous extractive.....	0	5
Volatile oil.....	a trace	0
Wax.....	0	2
Gum.....	9	3 to 4
Starch.....	33	30 to 35
Vegetable medulla.....	0	17
Woody fibre.....	39	12
Water.....	0	9 to 10
	100	97

In the ashes of the root, Planche found calcareous and potash salts, oxide of iron, and silicic acid.

The non-existence of tannic or gallic acid in this root, is shown by the absence of any change when sulphate of iron, tar-

tar emetic, or gelatine, is added to an infusion of it. Unlike many other roots, Calumba does not contain any free acid for its infusion does not redden litmus.

Oderous principle.—The odour of the root has by some been supposed to depend on a

volatile oil, traces of which are said to have been obtained by Planche. Water distilled from the root possesses the odour of the latter.

Active principle of Calumba.—The active principle of Calumba, whatever may be its nature, is, as it exists in the root, soluble in both water and alcohol.

According to Planche it is a *yellow bitter matter*, which he says is soluble in water and alcohol, and gives no precipitate with either the salts of lead or with infusion of galls.

Some have suspected the existence of a *vegetable alkali*, and in favour of this opinion two facts have been adduced—namely, the precipitate caused by an infusion of the root with an infusion of galls, and the solubility of the active principle in alcohol. But these reasons are hardly sufficient. Starch, which exists in Calumba, gives, with infusion of galls, a precipitate. The late Dr. Duncan suggested that the active principle might be of the nature of *picroroxia*, as the plants which yield calumba and cocculus indicus belong to the same genus. This opinion has also been expressed by Buchner, who endeavoured to strengthen it by experiment. One grain of the ætherial extract, purified from the waxy matter by repeated solution in water, was applied to a wound in a rabbit, and in ten hours proved fatal to the animal. In another similar experiment, three grains were not fatal. In the American translation of MM. Edwards and Vavasseur's "*Manuel de Matière Médicale*," we are told that Dr. Conwell has obtained an alkaline principle which he terms *Columbia*.

Wittstock states that he procured sixty grains of a crystallized, odourless, very bitter substance, which was neither alkaline nor acid, from eight ounces of Calumba root. This substance he has termed *Columbine*. It is fusible; very slightly soluble in water, alcohol, æther, or the volatile oils; but dissolves in acids and caustic alkalies; its best solvent being acetic acid. It is unaffected by metallic solutions, and by infusion of galls. If this be the active principle of Calumba, it is clear that its properties must be modified by the other substances found in this root.

Starch.—This, as will be evident from the analyses of Planche and Buchner, forms a considerable portion (about one-third) of Calumba root. Its presence is readily detected by iodine; if the root be moistened with water and then touched with the tincture of iodine, a black spot is immediately produced. The infusion or decoction of Calumba becomes blue when iodine is added to it. The large quantity of starch in Calumba root renders it an easy prey to insects.

False Calumba; American Calumba; root

of the Frasera Walteri.—The *Frasera Walteri*, a plant belonging to the natural order *Gentianaceæ*, and to class *Tetrandria*, order *Monogynia*, in the Linnean arrangement, is a native of the southern and western portions of the United States, and is very abundant in Arkansas and Missouri. From the resemblance of the root, both in appearance and medicinal properties, to that of the *Cocculus palmatus*, it has received the popular name of *American Calumba*.

Dr. Duncan states, that a *false Calumba* root, the produce of this plant, has been imported from the United States into Liverpool; but I have never met with any samples of it in this country.

Some years since, it was introduced into France, and sold for genuine Calumba. Guibourt pointed out its distinguishing characters; he called it *fausse racine de Calumbo*, and from an erroneous notion of its origin, it was sometimes called *Colombo d'Afrique*.

It is said to resemble very strongly the true Calumba; but the samples I have received from France, would not, in my opinion, be confounded in this country with the real calumba. The pieces very closely resemble those of gentian root.

The root of *Frasera Walteri* may be readily distinguished from the true Calumba by the following characters:—

1. It undergoes no change when touched with tincture of iodine; hence it contains no starch.

2. It becomes blackish green when treated with sulphate of iron, and slightly precipitates gelatine; showing that it contains tannic acid.

Now I have already stated and demonstrated that the true Calumba contains about one-third of its weight of starch, and gives no indications of containing tannic acid.

The root of *Frasera Walteri* is official in the Pharmacopœia of the United States. Its effects and uses are like those of gentian.

Physiological effects.—Calumba is an excellent tonic; it promotes the appetite, assists the digestive process, and improves the quality of the secretions from the gastro-intestinal mucous membrane. By some it is considered as specifically influencing the liver. It is not a stimulant; for Dr. Percival took a scruple of it on an empty stomach, but did not observe that it had the least effect on the regularity, fulness, or velocity of the pulse. In another experiment he swallowed half a drachm: in ten minutes his pulse was fuller, and slower by three beats, and continued so for three-quarters of an hour. In consequence of the quantity of starch and gum which it contains, it is ranked by some pharmacological writers among what they term mucilaginous tonics, in which

ist they place the *Cetraria islandica* and *Simaruba* bark. From both these, as well as from quassia, it is distinguished by its aromatic properties. In some respects (namely, in its tonic and aromatic qualities) it approximates to rhubarb, but is devoid of the purgative and astringent properties of the latter. Its want of astringency distinguishes it from the astringent tonics, as cinchona. Full doses of powdered Calumba, given when the stomach is very irritable, cause vomiting. It does not appear either to constipate or relax the bowels. We are not acquainted with the effects of very large doses of Calumba; but if Buchner's experiments, already detailed, with the extract of this root, be correct, it is a dangerous remedy. Further observations, however, are required in order to confirm his statements.

Uses.—The following are the principal uses to which Calumba is applied:—

1. *To check vomiting.*—The power possessed by Calumba of checking vomiting has long been remarked. It is, however, principally observed in those cases of what we may call sympathetic vomiting; that is, vomiting depending on the sympathy existing between the stomach and some distant organ, as the uterus or kidneys. Thus it is frequently serviceable in the nausea and vomiting which frequently occur during pregnancy; in children, when vomitings take place during dentition, Calumba is oftentimes serviceable, especially when combined with chalk or magnesia; occasionally it gives temporary relief in the vomiting arising from disease of the kidney. There are several other cases in which its tendency to allay sickness is observable, as in bilious colic and habitual vomiting. I have seen the most satisfactory results from the combined use of infusion of Calumba and effervescing draughts (composed of citric acid and bicarbonate of potash), in those occasional vomitings especially observed in delicate females, and which are commonly termed bilious attacks. The violence and continuance of the vomitings are diminished by these remedies; and after the attack, the continued use of the Calumba has reduced the frequency, and in some cases prevented the occurrence of future attacks.

In order to satisfy himself of the anti-emetic qualities of Calumba, Schwilgue gave it when vomiting had commenced, after the use of emetic tartar or ipecacuanha. "Frequently, but not constantly," says he, "I have seen the vomiting arrested. I have often administered the Calumba along with the emetic tartar and ipecacuanha: vomiting in general occurred, but it was milder, and was more slowly produced."

2. *In diarrhoea and dysentery.*—The German name for Calumba root is *Ruhrwurzel*, that is, dysenteric root. You would, there-

fore, be led to imagine that Calumba had some specific influence in this disease. That it is frequently serviceable there can be no doubt, but not in that degree to warrant the name applied to it. It is adapted to the latter stages of dysentery, when all the inflammatory symptoms have subsided. In habitual diarrhoea it is exceedingly useful, when there are marks of inflammation.

3. *In a languid state of the stomach*, attended with want of appetite, indigestion, nausea, and flatulence, Calumba root, says Dr. Percival, is extremely beneficial. The experience of the last sixty years has fully justified the praise bestowed on it by this eminent physician. It is of all tonics the least likely to disagree with the stomach, and is frequently tolerated when any other would be immediately rejected.

Administration.—It may be given in powder in doses of ten grains to a scruple or half a drachm. But the most eligible form for exhibiting Calumba is that of infusion, in doses of one or two fluid ounces. The strength of it is, according to the London College, one drachm of the root to four ounces of boiling distilled water. It very speedily undergoes decomposition, owing, as Planché says, to the substance which he terms animal matter. The tincture of Calumba is a very useful adjunct to the infusion; or it may be taken alone in doses of one or two drachms.

COMPARATIVE MORTALITY OF THE RICH AND OF THE POOR.

To the Editor of the Medical Gazette.

SIR,

IN the beginning of last year my notice was attracted by a paragraph which appeared in all the newspapers, and afterwards in your MEDICAL GAZETTE, announcing the new doctrine of Dr. Casper, who had endeavoured to establish the superior longevity of married persons, male and female; whereupon I sent you a letter (see MEDICAL GAZETTE, March 19, 1836), showing that no such result was deducible from the Mortuary Register of S. Sulpice (inserted by Deparcieux), on which Dr. Casper founds his main argument; and, moreover, that the same work of Deparcieux contains a complete refutation of it, in the recorded ages of nearly 10,000 monks and nuns who were bound to celibacy.

Probably I should not have concerned myself with Dr. Casper's bold speculation, had it not threatened serious injury to civilized Europe by the virtual discouragement of life insurance and valuation of leases, and other survivor

ships to an immense amount; for the contingency of marriage is evidently incalculable, and yet, according to Dr. Casper, is an element which ought to be taken into account in all such calculations.

Dr. Casper's *Lebensdauer* has since found its way into England, and another of his speculations has attracted public notice, by a contrast of the duration of life among the rich and among the poor, which he exhibits in a table, and also by lithographed lines of life, accompanied by a commentary of his own.

"We cannot see without astonishment," says Dr. Casper, "that the comforts enjoyed by the rich extend the duration of life itself. Compared with the poor, twice as many of the rich attain to the age of 70; three times as many the age of 85; and four times as many the age of 90. In other words, the average duration of the life of the rich is 50 years, of the poor little more than 32 years; a difference of 18 years of life between the prince and the pauper."

This result, which excites the astonishment of Dr. Casper, may reasonably excite in others attention to the materials on which it is founded; and herein the novelty of having recourse to genealogical tables, as printed in an almanack, is first to be noticed. Individuals who die unmarried, or without issue, have little to do with the family tree, being always noticed significantly as *S. P. (sine prole)*, and, unless personally conspicuous in family occurrences, are not likely to appear in any transcript of genealogy, much less in an almanack; the printer of which, of course, aims at brevity in his compilation. Much less likely to be recorded, or even noticed, are those who die in infancy and childhood; and accordingly

Dr. Casper's table assigns no more than 44 deaths among 713 children under ten years of age. But there is no instance in any other published table of mortality, of less than one-third dying in the first ten years of life—that is, 238 in 713, or 333 in 1000; and Dr. Casper cannot, therefore, be dissatisfied if, in favour of the select class, and for the sake of obvious calculation in a subsequent table, their mortality is assumed to be 287 in 1000, instead of 62 in 1000, as assigned in his table*.

In the foregoing extract from Dr. Casper, we are told that the expectation of life among the rich is 50 years; so that the total number of years lived by his 713 individuals must have been

$$[36006 \cdot 5. \frac{36006 \cdot 5}{713} = 50 \cdot 5 - \cdot 5 = 50 \text{ yrs.}]$$

But if his radix, by adding 243 to his 44 deaths, becomes 1000 instead of 713, and the number of years lived (by a reasonable assignment of three years of life to each of the 243 added individuals dying under ten years of age) becomes 36,735, the result assigns to the rich no more than $36\frac{1}{2}$ years as their average duration of life, instead of 50 years—

$$[36006 + 729 = 36735 = 36 \cdot 735 - \cdot 5 = 36 \cdot 235 \text{ yrs.}]$$

It is true that the average life of the select class in Germany (as elsewhere) probably exceeds 40 years; but the anomalies in Dr. Casper's entire table are such as invalidate any result deduced from it,—as he himself will candidly confess on comparing it with the Law of Mortality in Belgium according to M. Quetelet, and with that of Sweden, which differ but little from our English tables; but I prefer them, as nearer to Germany, as well as being founded on very ample materials.

Age.	Law of Mortality in each period.		
	Dr. Casper.	M. Quetelet, 1832.	Swedish, 1795.
30—35....	31	29	29
35—40....	41	29	30
40—45....	51	30	35
45—50....	48	31	37
50—55....	66	36	41
55—60....	47	40	47

* It is remarkable that Dr. C. himself (p. 39 of his *Lebensdauer*) shows, that, in Berlin, 461 males in 1000, 469 females in 1000, die in the first

ten years of life. This mortality may exist in a populous city; but the superiority of male life is unexampled.

Your readers, in examining the above columns, are requested to understand that they are all worked on the common radix of 1000; and the irregular aberration of Dr. Casper's column from the other two succeeding columns, sufficiently proves that, from whatever cause, the Genealogical Almanack is not a secure basis on which to construct any calculation of the expectation of life; and I request attention to the remarkable fact, that the select class of Dr. Casper exhibits, in some instances, a much greater mortality between the ages of 30 and 60 years than the entire population of Belgium and Sweden,—a fact entirely subversive of his argument, even supposing his data to be of any value.

I know not whether, after this exposition, I am justified in asking the further attention of your readers to Dr. Casper's column exhibiting the mortality of the poor of Berlin,—of those who, in case of disease, are attended by medical officers at the expense of the public. The poor do not often accept such aid unless attacked by a dangerous disease; and to rely on the duration of life among such persons as a general rule, is quite as novel as the application of a Genealogical Almanack in the case of the rich. I really cannot imagine by what process of ratiocination Dr. Casper can advisedly ascribe to patients who die in a public hospital the same duration of life as to others generally, many of whom either escape disease or survive it, and die of old age. I forbear to examine into the aberrations of a table founded on such an assumption. Dr. Casper has sufficiently approved himself, by his medical statistics, and his *Lebensdauer*, to be an industrious collector of information, and has displayed his results in well-arranged tables and diagrams; but his good qualities will not be conducive to the public good until he has banished from his mind that love of the marvellous which, once admitted, puts to flight all other considerations.

I can very well understand, perhaps I have myself felt in my own experience, that when the mind has been led into a hopeful investigation, in the progress of which the same mind happens to discover its own error of induction,—or when an impossible or absurd result of calculation demonstrates the unsoundness of the materials on which it has

proceeded,—I can understand that in such a case it may cost the inquirer a pang in destroying the abortion and rejecting the intellectual labour of days or weeks. But this kind of sacrifice is absolutely required by the moral sense, which is conventionally ascribed to all those who undertake to instruct mankind in useful knowledge; for to say that such knowledge is not advanced by the publication of error, does not express the whole truth: the mischief is of a positive description, because the reader is thereby drawn aside from better occupation, and his time must be afterwards expended in refuting or perusing the refutation of the unfounded speculation which has unadvisedly been placed before him.

Still worse will be the result, if those who rely on an accredited author are misled into an unlimited train of error practically injurious to mankind. Dr. Casper himself furnishes an example of this, when he imputes to marriage consequences which, unrefuted, would go near to abolish all life assurances; and, in the present instance, into a speculation subversive of amity and good will between the different grades of human society; and regarding which I shall only add, that as the population of England and that of Prussia have increased at the same rate since the peace of 1815, the difference of condition between the rich and the poor cannot be very unlike in the two nations; and that in England the advantage of the select class, of those who are concerned in pecuniary transactions with government, is not very great. In the opinion of Mr. Finlaison (whose calculations on the lives of upwards of 20,000 public annuitants are known to be unimpeachable), the expectation of life throughout the entire population of England, in the year 1821, had reached that of the select class in the year 1786,—a fact which would be incredible, unless we knew that the annual number of deaths in England did not increase during thirty-six years (from 1780 to 1815), although the population increased from 7,814,000 to 11,525,000, or 47 per cent., during that time. It is true that this remarkable prolongation of human life may have extended in some degree to the select class; but it would be outrageous probability to estimate the life of the select male as more than equal to that of females generally in all classes of

society. The experience of the Equitable Assurance Society (published in 1834), where a great majority of the insured are males, confirms Mr. Finlaison's calculations.

This mention of a Life Assurance Office reminds me that I ought not to conclude this letter without stating, that in the opinion of those most conversant in life assurances, the usual certificates of health required of the insured, and upon which Dr. Casper places great reliance, are fully balanced and counteracted by insurances effected by individuals conscious of concealed disease, and sometimes, though (we may hope) rarely, by the flagitious practices of those who insure lives which they intend to shorten afterwards.—I remain, sir,

Your obedient servant,

JOHN RICKMAN.

Feb. 14, 1837.

ERRORS OF LAENNEC AND OTHERS

RESPECTING THE

REGIONS OF THE CHEST.

To the Editor of the Medical Gazette.

SIR,

SOME apology may be necessary for bringing the following subject so often before your readers; but if they consider how much it has been practically misunderstood, and the perplexity and errors which have been the result—if they consider the respectable authorities who have contributed to the spread of incorrect opinions concerning it—if they consider what an apparently fair ground the consequent mistakes have furnished to many, for treating the physical signs with neglect or disdain—and finally, if they consider that the exposure of error often facilitates the establishment of truth, they will perhaps feel disposed to view any efforts to throw light upon it with some degree of indulgence.

I might have avoided much repetition in the notice of Laënnec's regions, by putting under the same head those that yield similar results; but I have preferred the risk of being tiresome to that of being charged with intentional, or unintentional, misrepresentation of his views. With regard to other fre-

quent repetitions I cannot offer so legitimate an excuse.

In his "*Traité de l'Auscultation médiate*," Laënnec has given a division of the surface of the chest into different regions, with the characters of sound on percussion which, according to him, belong to each. There are, in his account of these regions and sounds, some errors, either direct or implied, which I shall now endeavour to point out, arranging my remarks under a few heads.

He says, first, that in the mammary region, which commences "*au-dessous de la quatrième côte et finit à la huitième*," percussion cannot be employed "*chez la plupart des femmes*," and that in men it seldom yields as much sound as the "*région antérieure-supérieure*," on account of the thickness of the lower edge of the great pectoral muscle.

A much better explanation of this comparative dulness will be found in the position of the heart and liver, the latter of which is, with few exceptions, near the surface in the greater part of the said mammary region, on the right side, and very frequently also on the left.

The circumstance of Laënnec not having taken the heart into consideration in his account of the regions of the chest, has been pointed out by M. Andral.

2. That in the "*région sous-mammaire*," which commences "*au-dessous de la huitième côte*," and ends "*au rebord des cartilages des fausses côtes*," the sound is almost always "*peu clair*" on the right side, "*à cause du volume du foie*." That on the left side, on the contrary, it is often clearer than natural, and almost tympanitic, from distension of the stomach by gases.

3. That in the "*région latérale*," which commences "*au-dessous de la quatrième côte*," and ends "*à la huitième*," the sound is always clear on the left side; that "*souvent il l'est notablement moins*" on the right; "*ce qui indique toujours que le foie remonte plus haut qu'à l'ordinaire, et que le poumon droit refoulé en haut, en devient un peu plus dense et moins rempli d'air. Car le foie ne remonte jamais réellement, au moins lorsqu'il est sain, plus haut que le niveau de la sixième ou cinquième côte au plus.*"

It is to be hoped that Laënnec is mistaken when he asserts that the healthy

liver "ne remonte jamais plus haut" than the level of the fifth rib; as, on that supposition, diseased livers are as much the order of the day amongst us, as was ever dreamed of by the strongest partizans of hepatic affections.

The general rule, the *more* than general rule, is, that the liver *does* rise above the level of the fifth rib*, which explains very well the fact, that the sound in the "région latérale, à droite," is not only often, but almost always, especially in its lower parts, "notablement moins clair qu'à gauche," unless there is disease on the left side diminishing the natural quantity of air, or emphysema or pneumo-thorax on the right†.

4. That in the "région latérale-inférieure," which commences "au-dessous de la huitième côte," and ends "au rebord des cartilages des fausses côtes," the sound is, "par la raison que nous venons d'exposer," often "tout à fait mat" in the "région latérale-inférieure droite," and that it is almost always "beaucoup moins sonore" than in the left; that in this last, on the contrary, the sound is often clearer than natural when the stomach is distended by gases; and that "cette résonnance claire peut encore avoir lieu en pareil cas, lorsqu'elle même que la partie inférieure du poumon gauche serait engorgée, ou qu'il existerait un épanchement dans la plèvre de ce côté."

If we consider what is said and what is omitted, concerning the stomach, in the account of the regions "mammaire," "sous-mammaire," "latérale," and "latérale-inférieure," it will be evident, I think, that there is a remarkable oversight. We are taught that, in the left "région sous-mammaire," the distension of the stomach by gases produces a sound clearer than natural, and almost tympanitic; and also, that in the left "région latérale inférieure," the distension of the stomach by gases produces a sound clearer than natural. This is perfectly true; but when compared with the total silence as to the stomach producing any effect on the sound in the "région mammaire," and the "région latérale," we may fairly

infer that Laënnec supposed its influence on the sound not to extend above the eighth rib in these two regions, even when the stomach was distended by gases.

Now the fact is, that when the stomach is distended by gases, it affects the sounds as high up as the sixth, the fifth, or even the fourth rib.

The cases in which the stomach gives its sound no higher than the eighth rib are mere exceptions, and that not only when there may be said to be *distension* of the stomach by gases, but in the ordinary state of things.

It is extraordinary that Laënnec should take no notice of the intestines in this account, although their presence high up often produces a very marked increase of "sonorité." The circumstance of his stating that in this lower lateral region, the stomach distended by gases might produce a clear resonance, even though the lower portion of the left lung should be "engorgée," or though there should be an "épanchement" in the pleura of that side, is not calculated to diminish our surprise, when compared with his want of knowledge as to its influence high up.

He mentions, however, that in the "région dorsale inférieure," which commences "à la hauteur" of the inferior angle of the scapula, and ends "à celle de la douzième vertèbre dorsale," the sound on the left side often presents over the whole extent of that region "la sonorité trompeuse" before mentioned, and which he attributes to the stomach being distended by gases.

It should be borne in mind that Laënnec scarcely* employed mediate percussion; but the points on which I have ventured to criticize him might, I think, have been made out by immediate percussion, especially as he was unrivalled in that respect.

In the "Notes et Additions au Traité de l'Auscultation médiate de Laënnec," by Mons. Meriadec Laënnec and Mons. Andral, this latter thus expresses himself regarding Laënnec's account of the sounds of the chest, with the exception as to the heart above mentioned:—"Dans cette appréciation, si nette et si vraie, des différences de sonorité que présentent les parois thoraciques dans les divers points de leur étendue," &c.

* This is not offered as an original remark, anatomically speaking.

† The preceding remarks have solely reference to the level of the fifth rib as the standard of the healthy liver; but do not Laënnec's words imply that he considered this as the exception, and the level of the sixth as the utmost average height?

* I am not quite sure whether he employed it at all.

The almost unqualified praise which M. Andral gives on this occasion is perhaps quite as surprising as the original errors of Laënnec, which he thus adopts as his own.

I shall now make a long quotation from M. Piorry, which will serve to show that *mediate percussion* did not save him from error as to the ordinary height of the liver and its relative situation. "A droite et lorsqu'après avoir percuté le haut de la poitrine, on explore plus inférieurement, on trouve ordinairement à quelques pouces au-dessous du mamelon, un peu plus de résistance au doigt et de la matité. Cela n'est bien sensible qu'à l'aide d'une percussion assez forte; à mesure qu'on descend la dureté et le son obscur deviennent de plus en plus apparens, de telle sorte que tout à fait en bas, dans le thorax, se retrouvent les caractères plessimétriques dus à la présence du foie; c'est, en effet, cet organe qu'on rencontre sur ce dernier point*."

The opinion that you must ordinarily descend "quelques pouces" below the nipple before you find "un peu plus de résistance au doigt et de la matité," and that "cela n'est bien sensible qu'à l'aide d'une percussion assez forte," is so utterly contrary to what almost daily observation teaches me, that it might, combined with the opinions combated above, lead to the supposition of there being some difference in the structure of the inhabitants of Paris and London with regard to the height of the liver and the diaphragm generally.

At page 162 of the same work we are told that it is in general "à un ou deux pouces au-dessous du mamelon droit," that the liver commences in the greater part of mankind, and that its lower edge terminates "au rebord costal."

In connexion with M. Piorry and *mediate percussion*, I may take the opportunity of stating, that the practice of percussing on one of the fingers was first proposed by Dr. Skerrett, who, with myself and several others, attended the early public demonstrations of M. Piorry in the dissecting-rooms near La Pitié. I speak from personal and positive knowledge of the circumstances; and I recollect perfectly his urging the subject on the attention of M. Piorry, who appeared to me at the time indisposed to entertain the proposal, and who seems subsequently to have forgotten

the particular individual with whom it originated.

It has been mentioned to me by gentlemen who have attended the clinique of M. Louis, that he gives a rule for estimating the average height of the liver; but their information is not sufficiently positive and precise to justify me in venturing to give any definite opinion about it.

In those individuals whose diaphragm on the left side runs at a considerable distance from the ribs, some tact in percussion is requisite, in order to make the stomach or intestines *tell* through the lung high up*. Sometimes, too, the liver, extending far to the left, renders the stomachal or intestinal sound from percussion in front distant and feeble; still, with a certain degree of skill, it is often possible to ascertain, not only through a portion of liver, but also through a portion of the heart, when this organ lies in a slanting direction on the diaphragm, the intestinal or stomachal sound behind them. I may mention, that in such cases also the kind of revolving or tilting motion alluded to in a former number†, will, even through the heart, frequently indicate the height of the diaphragm behind it, and consequently that of the stomach or intestines.

An objection is sometimes made, that the height of the diaphragm varies so much during respiration as to render fallacious any practical conclusions attempted to be drawn from a supposed knowledge of it at any given moment.

To this I would answer, 1st, That the variations during the ordinary act of respiration are too slight to lead to any practical mistake. 2d, That even in strong abdominal inspiration the movement is not one of much depression, but of the tilting or revolving character above mentioned; and that this last motion, properly understood, renders more easy a knowledge of the diaphragmatic level. 3d, That opinions drawn from living animals whose abdominal parietes have been cut through, are not conclusive on the subject.

In a note to his communication "On the theory and practice of Percussion as a mode of Diagnosis‡," my friend Dr.

* In speaking of the stomach or intestines, I do not mean to imply that they cannot exist high up together.

† Dec. 10, 1836.

‡ MEDICAL GAZETTE, Jan. 21, 1837.

* Du procédé opératoire, &c. p. 53.

Williams, in speaking of the height to which the diaphragm rises in the chest, represents me as having taken great pains to investigate this matter. Perhaps I may be excused for stating that I have taken great pains, not to ascertain simply the height of the diaphragm, but those marks and movements, whether appreciable by sight or touch, which indicate in different individuals, not only the height of the diaphragm, but, to a certain extent, the distance at which it lies from the ribs in different parts of its course; thereby rendering it possible to foretell in any particular case, with considerable practical accuracy, the degrees of resonance on percussion, and the state of the respiration in those parts of the chest which lie below the diaphragmatic level, and of course to estimate any marked deviation from the healthy state.

If, on the other hand, the inquiry has been begun by the general and local signs, this method may be found useful in confirming or invalidating the conclusions drawn from those sources. The difficulty of describing the indications furnished by sight or touch as to the course of the diaphragm, deters me from attempting it at present, but I hope to be able to do so before long with some degree of success. In the meantime, any one who may feel inclined to investigate the subject practically, will meet with a corresponding disposition on my part.

By the remark, that the fact of the diaphragm rising thus high up in the chest had been little attended to by physicians, Dr. Williams did not, I believe, mean to convey an assertion that he had ever known it to be attended to either much or little by any physician or physicians.

The perusal lately of an article by Dr. Stokes, in the 7th number of the Dublin Journal of Medical and Chemical Science, induces me, in the hope of preventing the recurrence of such a mistake, and dissipating a little of the obscurity which sometimes hangs about such cases, to make some remarks, and throw out some conjectures which I should otherwise have reserved for further examination.

In that article there is mention made of an operation for empyema, in which the diaphragm was pierced, from the instrument having been introduced too low down. It has been for some time an object with me to ascertain how far

that lateral depression* which, in the majority of individuals, indicates the level of the diaphragm on the corresponding side, would be affected by consolidation of the lungs or effusion into the chest. The cases, whether of tuberculization or hepatization, which I have had an opportunity of examining, appear to justify the positive conclusion that this depression is not changed by those diseases, and that it there also indicates in general the diaphragmatic level. With regard to effusion into the chest, I wish to be understood as speaking with hesitation, but on the one hand some cases of the kind that I have seen appear to favour the idea that either the lateral depression is not affected, or that it is merely thrown a little higher up; and on the other, I am not aware of having met with a single exception to this rule. If this opinion proves to be correct, it will suggest the practical caution of not introducing the instrument below such depression, unless there shall be circumstances which prove that the diaphragm is displaced downwards to a sufficient degree.

In the case mentioned by Dr. Stokes, the diseased side at the time of the operation was in a state of contraction, and it is possible that this circumstance may cause some doubt and difficulty. However, if it is recollected that as a general rule the depression is a little higher on the right side than on the left, an examination of its height on the sound side may lead to a probable conclusion as to its natural height on that which is diseased.

There is one point which I must not omit to mention. Although it may be inferred that the diaphragm, unless displaced downwards by disease, rises as high as the lateral depression, it cannot be inferred that it rises no higher. I would venture to propose an hypothesis which will go far, I think, towards explaining a great number of cases, and reconciling some apparent contradictions. It is this; that there is in every individual a depression on each side corresponding to the natural height of the diaphragm on that side, and that this depression remains, although from some cause, such as diseased liver, effusion into the abdomen, &c. the diaphragm should be either temporarily or permanently thrown higher up than

* Med. Gaz. Dec. 10, 1836.

three or four days nothing but weakness, with a tiresome cough, remained in the majority of instances,—a weakness, however, greatly disproportionate to the duration or danger of the disease. Two-fifths of the cases noted as influenza by the house-surgeon were of the kind just glanced at; the remaining three-fifths were complicated as follows; viz. with

Pleuropneumonia	36
Bronchitis, mostly chronic, and combined with Emphysema } Pulm. and Morb. Cord.	52
Phthisis	25
Pleuritis	5
Fever, in several instances Typhoid	25
Rheumatism, Chron.	2
Morb. Chron. Ventriculi	3
Croup	3
Ptyalism	1
Encephalitis	1
Morb. Chron. Cord.	3
Pericarditis	1

Of course the symptoms must have varied much in the second class, or complicated cases. In numerous instances the complicating diseases were at first so masked by the influenza, as not to be easily recognizable. Without the aid of the pleximeter or finger and ear-tube; indeed, it appeared to me nearly impossible in several cases to arrive at a safe or satisfactory diagnosis, more especially in persons advanced in life. The irregularity observed in the course of the functional signs did not in any material degree of course extend to the physical signs; so that pneumonia, phthisis, disease of the heart, and hypertrophy of the ramifications of

the bronchus (or emphysema pulm. & catarrh. chron.), which were the most frequent and formidable complications were generally as easily identified as usual. In every case the influenza, if distinguished at all, was readily detected, whatever its complications, if attended to within the first day or two; after that period it often, in bad cases, became absorbed in the effects of the graver complicating disease.

Mortality.—The mortality with us, as elsewhere, amongst populations embracing indifferently individuals of all ages, sound and unsound, was very considerable during the period so often specified above. I do not know that any simple case was lost from influenza unaided by previous disease or subsequent complication; but so large a portion of the subjects of our influenza had had previously tuberculated lungs, diseased bronchial ramifications or hypertrophy of the heart, and the instances in which pleuropneumonia was excited were so numerous, that

We lost in the six weeks, from 31st December, altogether	118
Cases, to which must be added, deaths in the infirm wards of the Workhouse, same period ..	21
In the out-door practice also there were some deaths (exclusive of the mortality of the cases transferred to the Infirmary), amounting in the same period to	40

Remarks on the Table of Ages.

From the preceding table it would appear that aged persons have enjoyed no such immunities during the late epidemic as they have been found, or, for want of counting, perhaps, supposed to do in former epidemics*. More than half of the cases were above 40, while a fourth part nearly were above 60. But the table represents the case too favourably for the other extreme of life, owing to the nursery and school children having usually not been so severely affected as to require hospital treatment. Another generally received opinion, however, is confirmed by our experience, viz. the potency of pectoral disease as a predisposing cause; this appears strikingly from the table of complications. For though the complicated cases were received into the Infirmary in much larger proportion, of course, than the simple cases, yet the number of the former is too considerable to be overlooked, or attributed to universality of diffusion of the epidemic causes, rather than to peculiar susceptibility in the subjects.

I have added the deaths of all diseases, but none for influenza separately, for the obvious reason that influenza proper produced no deaths.

Amongst the causes I have seen no reason to reckon contagion; perhaps I have not looked sufficiently, or inquired for it. Like all other epidemic diseases, the present, whether contagious or not, certainly commenced at first without contagion, and has probably, as I think, been exclusively reproduced and continued by recurrences of one or more of its first causes: what those first and essential causes are, I think with Pringle (*Med. Obs. and Inq.* vol. vi.) is still a problem for solution.

Morbid Appearances.

During the epidemic numerous opportunities presented themselves of investigating its anatomical characters; and in every instance I found that the fatal result might be attributed to previous disease, or to organic deterioration from lapse of years. The youngest was a female, 8 years old, who sank under double pneumonia supervening on tuberculation. There were a male and a female between 20 and 30; a male and a female between 30 and 40; a male and

two females between 40 and 50; between 50 and 60 there were five males and two females; and between 60 and 70, six males and one female.

The complicating diseases were—

Chronic disease, with enlargement of the heart and bronchial ramifications, without acute pulmonary disease.....	9
Chronic disease of the heart and bronchia, with recent pleuropneumonia.....	6
Chronic disease of the heart, with phthisis (1), or recent pericarditis (1)	2
Pneumonia and pericarditis.....	1
Phthisis with pneumonia	1
Pneumonia.....	1
Pneumonia with suppuration of kidneys	1
Pneumonia, morb. cord., and arachnitis	1

I observed nothing constant in the post-mortem appearances but extreme injection of the trachea and all its branches, and in several cases thickening of the mucous lining of the passages. But those are nothing more than are, according to my observation, to be met with in a greater or less degree in almost every case of asthma, chronic catarrh, and old disease of the heart. It may be thought singular that disease of the heart should have occurred so often, much oftener than phthisis, being eighteen times out of twenty-two; and I should probably, some twelvemonths or more since, have been struck myself by such a statement. But it is undoubtedly true, that disease of the heart frequently escapes the observer who trusts to his eye as a means of admeasurement. When, as often happens, there is no pericarditis, nor any valvular disease, and when hypertrophy, if existing, is distributed pretty equally over the organ, there is a great chance of its escaping notice, unless very considerable; more especially if the inspector have defective information respecting the health of the deceased. To guard against error from that quarter, I have for some time weighed every subject inspected on account of disease of the heart, entire in the first instance, and then after a careful examination of the pectoral viscera, weighed the heart separately, after washing; and in this way have satisfied myself that amongst the labouring classes at least, hypertrophy of that organ is a still more common and fatal

* Hancock, *Cycl. Prac. Med.*, art. Influenza, p. 5.

disorder than many or most physicians believe.

Treatment.—Regarding the simple influenza cases I have little to say. With warmth, water gruel for food, and repose in bed for a couple of days, they were usually convalescent, or about to be so, whatever might be the medication employed, provided only that medication were not energetic. “*Res fuit herclé diætæ potius accuratæ ac debiti regiminis plerumque, quam medicinæ elaboratæ,*” (Huxham de ære, &c.) like its predecessor of 1743: occasionally, however, like the epidemic just referred to, “*multo plus curæ atque diligentie poposcit.*” In a great majority of cases, nearly all indeed, it was thought advisable to blister the chest, which usually gave to the bronchial irritation the relief desired. In some also leeching or cupping was cautiously employed; where the pain under the sternum was urgent, or pneumonia or pleurisy was apprehended, or where gastro-enteritic irritation was well marked. The ordinary internal medicine was antimonial mixture (gr. $\frac{1}{2}$ to 3iss.) with 2 or 3 drops of laudanum 4tis horis, which was generally found to answer well; but in several cases, probably 20, half a grain or a grain was prescribed with benefit. Purges were often called for by constipation at the commencement, and were at all times used without hesitation, according to circumstances. As soon as fever abated, animal food, beginning with broth, if not previously in use, was employed, with porter, wine, or other cordial according to circumstances. In 15 or 20 cases saburra and oppression were treated at first with emetic doses of antimony; and frequently the ordinary antimonial mixture operating on an irritable stomach, caused vomiting, which was found to be of service ultimately, however inconvenient in some cases at the moment. I do not know that bleeding was ever employed in uncomplicated influenza, but pneumonia or other visceral inflammations originating in influenza were encountered as usual. Into the treatment of the complicated cases it is unnecessary for me to enter, partly on account of the tediousness of a detail of so many various plans, but principally because influenza, not the diseases with which it was incidentally associated, is the subject of this communication. Suffice it in a general way to say that such cases were

treated variously of necessity, but always with a double regard to the gravet as well as to the transient and minor disease. Pneumonia and pleurisy were the complications that most frequently compelled us to deviate from our general method, and those were encountered by bleeding, both general and local, especially the latter, blistering, antimonials, and when less tractable on account of disease of the heart, age, &c. by mercury likewise, with or without opium.

Physician to the Mary-le-bone Infirmary, &c.
Wimpole Street, Feb. 13, 1837.

NOTE ON THE INFLUENZA.

To the Editor of the Medical Gazette.

SIR,

If the papers which have appeared in the medical journals are to be received as indicative of professional opinion, considerable difference exists both in the theoretical and practical views taken by different men regarding the nature of the epidemic recently so prevalent.

I am induced to trouble you with this communication, not from having any thing new in the way of hypothesis to present to your readers, but simply from the desire to place on record a few facts, on which I leave it for others to theorize if they think proper.

I presume that the cases I have seen, taken altogether, have been of more than the average degree of severity, first, because they have been treated partly in St. George's Hospital, where the slighter cases were not admitted; and secondly, because a certain proportion of the others have been patients, to whom I have been called by general practitioners, who have done me the favour to ask for my assistance. Now, setting aside the mere catarrhal affections of a few days' duration, the great mass of the others which I have seen has been made up of unequivocal examples of inflammation of the air tubes. This has principally been developed in the minuter branches, but not unfrequently has extended into the trachea, and sometimes even to the larynx. The inflammation, however, has not been limited to the parts just mentioned, but in a certain number of cases has affected other mucous mem-

branches in addition to the simultaneous participation of the air passages. Thus, taking 40 of the more severe cases, I find that 3 had well-marked symptoms of laryngitis; 3 had pleurisy; 4 had otitis, which in three terminated in purulent discharge of several days' duration; 1 had inflammation of the conjunctiva in both eyes; 4 have had inflammation of the posterior fauces; 2 have had swelling and inflammation of the parotid and submaxillary glands on the subsidence of the pulmonary affection; and in 3 erysipelas has followed on the subsidence of the primary attack. As in all the above there was a pulmonary affection, the result is, that 25 had bronchitis of different degrees of severity, and 15, in addition to this, had simultaneous inflammation of some other and for the most part analogous texture; while 5 had other forms of inflammation as sequelæ of the original attack. Of the entire number here referred to, 6 have died, 3 of whom, however, I saw only at a very advanced period of the disease, and therefore cannot speak of its early stage; 1 was a case in which erysipelas supervened upon laryngitis, and scarcely, I think, to be called a fatal case of "influenza;" the other 4 were cases of bronchitis, attacking persons who had been previously subject to pulmonary affections, and in whom the disease ended in suffocating effusion into the air tubes.

The general symptoms were, at the onset, chilliness (in one amounting to violent rigor), severe headache, great lassitude and depression, cough, with hurried respiration and feeling of distress, referred to the chest generally, with much pain, (as if the parts had been bruised,) extending along the diaphragmatic margin of the ribs, aggravated by coughing or deep inspiration. The cough was at first dry, but after a few days became loose, in favourable cases, and afterwards accompanied by free mucous expectoration. The crepito-mucous râle was for the most part pretty general in both lungs, and a graver ronchus in the larger tubes; while, in not a few cases, a kind of tremor or vibration was felt, by merely laying the hand flat upon the chest, over the situations of the larger bronchi. The pulse was in general considerably increased in frequency, but (unless in the cases in which pleurisy was combined) was soft and compressible. There was heat of

skin, but this diminished as the disease advanced, even in those cases which were running an unfavourable course.

In some of the published opinions of this epidemic, it has been argued that it was not essentially of inflammatory nature, because the patients did not bear bleeding well; but this I apprehend to be very frequently the case in bronchitis, as it also is occasionally in other inflammations—such as various forms of erysipelas. The disease in the present instance, as in bronchitis generally, has been by far most severe on those advanced in life, and it is familiar to all, that in them inflammation of the passages very rarely assumes the plastic form which it presents in early life. The principal source of danger, if I may so express myself, consists not so much in the activity of the inflammation as in one of its effects—namely, the increased secretion into the minute bronchi, by which the air is prevented from coming into contact with the pulmonary vesicles, so that the arterialization of the blood is arrested. Many of the patients whom I have seen, had more or less of a leaden tint, and all the four who died were deeply tinged—one of them as blue as I ever saw in cholera.

Of the four fatal cases alluded to, I had only an opportunity of examining two. The disease in one had lasted ten days, in the other a fortnight; in both the appearances were the same—namely, dark vascular redness of the mucous membranes, extending from the larynx to the minutest ramifications of the bronchi which could be traced. The smaller air tubes seemed to be literally soaked with fluid, while the larger were smeared over with viscid mucus, as adhesive as bird-lime. The lungs gorged with blood. In one, old adhesions of the pleuræ; but in neither any evidence of recent pleuritic inflammation.

The general treatment consisted in confining the patient to bed, exhibiting a draught containing ʒij. of liq. acet. ammoniæ, every four or six hours, acting gently on the bowels, and promoting expectoration by means of oxymel of squill and ipecacuanha. In the great majority of cases perspiration came on within the first two days, after which the symptoms gradually, though but slowly, abated.

If the disease assumed a more inflammatory character, that is, if there was more than the average degree of fever,

with hard dry cough, calomel, with James's powder, or tartarized antimony, was prescribed, which, in the more acute cases, was pushed to the extent of twelve grains of calomel, and two of tartar emetic, in twenty-four hours. In such cases blisters were also applied to the chest. If, on the other hand, the inflammatory symptoms were less marked, or had been subdued, the expectorants were strengthened by the addition of spirit. ætheris nitrici, and compound tincture of camphor. Where the debility was great, a draught, containing f. ℥ij. spirit. ætheris sulphurici, with mʒj. of dilute sulphuric acid, sweetened with some syrup, was of service, and was afterwards followed up by some bitter tonic, particularly cinchona, as soon as the pulmonary symptoms were subdued.

Where there was much oppression of the lungs early, and before effusion had taken place into the air-passages, leeches to the sternum, followed by blistering, were efficacious. When the larynx and trachea were implicated, too, leeches were applied; but, guided by former experience, I abstained from general blood-letting in all the cases, except those in which the pleura was implicated; but even here the venesection was not well borne, producing a greater degree of subsequent debility than we are accustomed to witness from similar depletions; and in one of those, where the patient required to be bled three times to twelve ounces, although the pleuritic symptoms were thus overcome, he was seized two days after with erysipelas of the scrotum, and thighs adjacent, which speedily produced partial sloughing, and required the exhibition of bark and wine.

So, too, with regard to the affection of the throat; this has rather shewn a flabby and relaxed condition of the membrane than acute inflammation. It has usually been attended with great pain in the deglutition of the saliva, while a mouthful of food could be swallowed without the same difficulty. Most relief was afforded in such cases by stimulating and astringent gargles.

In the cases where otitis took place, although the bronchial inflammation had not subsided when the former came on, yet it was no more complained of, and had disappeared when the discharge from the ear was established. Nearly

the same thing was observed with respect to the inflammation of the glands about the jaw—that is, by the time they were considerably swollen, the breathing was entirely relieved.

I am, sir,

Your obedient servant,
RODERICK MACLEOD, M.D.

Feb. 14, 1836.

REMARKS ON THE INFLUENZA OF 1837.

To the Editor of the Medical Gazette.

SIR,

If you think the annexed remarks on influenza of sufficient interest, perhaps you will give them a place in the *MEDICAL GAZETTE*.—I am, sir,

Your obedient servant,
R. J. P.

Kensington, Feb. 16, 1837.

The cases of the epidemic may be divided into three classes, according to the aspect of the symptoms.

1. Those cases, chiefly occurring in young persons, having the features simply of mild catarrh.

2. Those assuming more the aspect of rheumatic fever, to which catarrhal symptoms are attached only in a trifling degree, occurring also chiefly in the young and middle aged.

3. That severe form, prevailing most amongst the old, and more especially those who have the chronic bronchial affection so common to elderly persons.

In the first form there is generally chilliness or rigors, succeeded by heat; pain, often severe, in the frontal sinuses and nostrils, with feeling of suffocation from swelling of the membrane lining the back part of nostrils—often with bleeding from that part. Troublesome cough, from irritation referred to the lower part of trachea; especially teasing during the night; not relieved in the usual way by expectoration. The pulse weak, not much quickened; tongue slightly furred, and generally moist.

Treatment.—By confinement to bed, or to a room of equal temperature, these cases soon pass over. Recovery seems to be chiefly retarded by the depression

so marked in this disease, together with the persisting *dry* cough.

Saline and mucilaginous medicines, as mucil. tragac., or acaciæ, mist. amygd., or oxymel, with small doses of antimony and nitrate of potass. The night cough much relieved by ten grains of pulv. ipecac. comp. at bed-time, in mucilage, with spt. æth. nitr. 3ss., or made into pills with mucilage; by which a quiet night's rest is procured with great relief. The bronchial irritation may be much mitigated by mustard poultices applied (from half an hour to two hours) to the upper part of chest. Secretion may be promoted by the following pill every four or six hours:—

Ext. Conii. Pil. Scillæ C. aa. gr. ii.;
Pulv. Ipecac. gr. i.

Diet, arrow-root, gruel, whey, beef tea; with meat early in the convalescence.

In the second form the early symptoms are the same as in the first, but more severe: there is headache, much pain in the aponeuroses of loins, scapulæ, and limbs, often round the *margin* of chest, apparently in the tendinous structures external to the chest, sometimes extending over one side and suddenly shifting to the other; the pulse quick, and generally small and weak; the tongue furred, white and moist, often dry and yellow; trifling cough, and uneasiness in the air passages; the cerebral symptoms in some cases severe, often amounting to delirium. There is generally much depression; often syncope. The urine is small in quantity, and loaded with lithate of ammonia.

Treatment.—Saline aperients, with calomel and antimony at night. Leeches to the forehead in many cases, and to the chest, followed by blisters, when the pains about the chest are severe. Bleeding does not seem more effectual in giving relief than leeches, and is not well borne. Vinum colchici, in half-drachm doses, relieves the pains in the head and limbs; 10 grs. of Dover's powder, with nitre, at bed-time, is very useful in allaying pain and procuring rest. Where the tongue is much furred, great relief is obtained by purging the liver with calomel, followed by warm aperients, as rhubarb, magnesia, and dec. aloes, or rhubarb and tartrate of potass, or sulph. and carb. magnesiæ, with tr. card. co. As soon as the febrile symptoms have subsided, and the tongue

gets clean, quinine is the best tonic. The diet should be as nourishing as the stomach and system will bear.

In both these forms the depression of strength and spirits is very remarkable—quite out of proportion to the other symptoms.

In the third form the chief danger is from the large quantity of tenacious mucus secreted by the bronchial surface; the depression of strength causing great difficulty in its expectoration. The attack frequently appears but as an aggravation of symptoms previously existing, but whose features it rapidly changes. The strength sinks; the appetite fails; the circulation becomes languid; the strength is inadequate to expel the large quantity of bronchial secretion; the lips get blue, the intestines cold, and the patient soon sinks,—often in a few hours. In less severe cases, there is a lighter shade of these symptoms; the tongue is much furred—often brown and dry.

Treatment.—Much benefit is derived from blistering the chest, which should be done early in the case, so as to *anticipate* the severe symptoms. Squills, ipecacuanha, antimony in small doses (avoiding its depressing effects); and where antimony cannot be borne, the lobelia inflata (tincture) appear serviceable in clearing the bronchial tubes, in doses of 3ss. every six hours, with æther and ipecac. Where the tongue is much furred (as it is almost always), one or two doses of calomel, followed by hyd. c. creta, combined with rhubarb, or at night with Dover's powder. This form of opium appears to agree better than any other in this disease; perspiration is promoted and rest is procured, without that binding effect on the secretion which follows the other preparations of opium. Nourishment must be cautiously given from the first; such as beef-tea, jelly, yolk of egg, with warm milk, or whey; and where there is much prostration, with wine, or brandy. There is in many cases very troublesome vomiting; this is relieved by potass, soda, or ammoniæ carb.; effervescing with lemon juice. Warm milk, with soda-water added to it, is a pleasant beverage in these cases.

Amongst the young, one fatal case only occurred, in a publican of intemperate habits, and unhealthy condition.

— T. C., aged 30.—He suffered a few

days from the simple catarrh, and neglected it. Rather suddenly the symptoms took a formidable aspect. Hoarseness, hurried short respiration, frequent cough, with trifling expectoration of mucus; quick and *very weak* pulse; the voice soon diminished to a whisper; the stifled cough became almost constant; the skin clammy; lips blue; hands and feet cold; and nails blue. The chest throughout was dull to percussion, and the respiration scarcely audible.

The extreme prostration forbade depletion in any form; calomel offered the only chance, and it was given freely; 3 grains every 2 hours, with carbonate of ammonia every 4 hours. Warm wine whey was the only thing he would take.

A blister applied to the chest became gangrenous soon after vesication. He died 48 hours after the commencement of severe symptoms.

Post-mortem.—The lungs did not collapse when the chest was opened; they still crepitated on pressure; were thickly spotted over with petechiæ under the pleura.

The lungs, trachea, and larynx, were removed for examination. The membrane lining the *larynx* was of a deep red colour, with flakes of lymph in the ventricles, and on the chordæ vocales. Trachea intensely injected throughout, and coated with glairy adhesive mucus, as also the large bronchia; a red mucous fluid poured out of the trachea on inverting the lungs. The lungs congested and gorged with serous and mucous fluids, which oozed out abundantly on incising them. In some parts, especially in the lower lobes, consolidation of the structures had ensued, being the first stage of peripneumonia. Heart sound. Liver filled with yellow tubercles, and very hard.

NEW (?) METHOD OF TREATING HYDROCELE.

IN REPLY TO MR. TRAVERS.

To the Editor of the Medical Gazette.

SIR,

IN the *Lancet* of the 7th of May last I pointed out to the medical profession a new method of treating hydrocele—

namely, by puncturing with a very fine needle, until a drop of fluid oozes out on withdrawing the needle, and in three days the hydrocele will completely disappear, no matter in what quantity the fluid might have been collected. In the last number of the *MEDICAL GAZETTE* there is a letter from Mr. Travers, in which he seems to insinuate that he was the discoverer of that method, because he had punctured a hydrocele with an acupuncture needle a fortnight prior to the date of my letter. Such may have been the case I am not in a position to deny, although I must in justice to myself declare that I never heard of Mr. Travers deviating from the ancient routine of practice in the treatment of hydrocele or any other disease. But lest the public should imagine, like Mr. Travers, that my discovery and the appearance of the letter in the *Lancet* to be synchronous, I can bring forward evidence at any time that the operation had been performed two years before Mr. Travers conceived it, as he terms it. I even spoke of it in public to several medical gentlemen, who will, I have no doubt, vouch for the accuracy of the statement. It was not until I perfected the operation, and had seen many cases, that I dared to make public the extraordinary fact that a single puncture with the point of a fine needle into an encysted cavity is sufficient to cause the absorption of the fluid contained therein. The practice of making many punctures is not only useless and dangerous, but actually less likely to succeed than a single puncture; of this the profession in general (I mean general practitioners as well as hospital surgeons) will be convinced by experience. If Mr. Travers had read my letter attentively, he would have seen that I first introduced the method as a palliative cure; although I have seen cases where a radical cure was effected by the simple operation of puncturation.

As the method of puncturation for the radical cure of hydrocele differs in some respects from the palliative, as soon as I have satisfied my mind on the subject, I shall rejoice, though an humble individual, to contribute my mite towards the advancement of science.—I am, sir,

Your obedient servant,

D. LEWIS.

28, Artillery-place, West,
Bunhill-row, Feb. 14th, 1837.

TREATMENT OF HYDROCELE.

NOTE FROM MR. KEATE.

To the Editor of the Medical Gazette.

SIR,

ON looking over the contents of your last number (for 11th inst.), I saw "Account of a new method of operating for Hydrocele, by Benjamin Travers, Esq., Surgeon to St. Thomas's Hospital." My hopes of gaining information naturally led me to refer to his letter at page 737 of the GAZETTE, where I read the account, I must confess, with some disappointment, and was rather surprised to find that there was another claimant for the merit of discovering this supposed new method.

While I do not mean to intimate any doubt of the same ideas having occurred to each of these gentlemen without any knowledge of the other's theory or practice, or of any previous operation of the kind, I trust it will not be offensive to either of them if I assure you that the plan and the practice have been known and acted on for very many years by myself, and I dare say by others. By one other person I know it was performed I dare say twenty years ago, namely, by a friend of mine, who for some years practised as a physician in this town, and is now living in retirement in the country. This gentleman performed the operation on *himself*, as he was nervous about the injection, and fancied, as he said, that if he could convert ascites into anasarca, absorption from the cellular structure might cure the malady; and in his own case it was perfectly successful.

At his suggestion I tried it frequently, both at the hospital and in private practice; sometimes successfully, but more frequently the collection of fluid in the sac returned, and I generally found the patients impatient of the numerous punctures, and of the time required for the absorption. I remember talking to Sir Astley Cooper on the subject, and, as far as my recollection serves me, the plan appeared not to be new to him.

I cannot venture to mention the name of the physician in this letter, as I have no time to write and ask his

consent before the appearance of your next number; but I can have no hesitation in stating it to you in confidence, or to any gentleman who may think it worth while to ask me.

I am, sir,
Your obedient servant,
ROBERT KEATE.

Albemarle-Street,
Feb. 15, 1837.

[The name of the physician above alluded to is mentioned in a postscript, but as it is marked "confidential," we of course abstain from publishing it.—ED. GAZ.]

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALEMBERT.

Pharmacopœia Collegii Regalis Medicorum Londinensis. 1836. Printed by order of the College.

WE resume this week our remarks on the new edition of the London Pharmacopœia; and in the first place propose offering some further observations on the *Materia Medica*.

In various places the College quotes De Candolle as its authority, though most arbitrarily, and sometimes incorrectly. Thus his name is attached to *Aconitum paniculatum*, when, in fact, Lamarck should have been quoted; also after the different species of *Citrus*, we have "De Candolle" instead of "Risso;" and even the old Linnean name, *Amygdalus communis*, has "De Candolle" attached to it. If the College intended merely to indicate that De Candolle has adopted these names in his *Prodromus*, why omit quoting him after *Boswellia serrata*, *Papaver somniferum*, *Astragalus verus*, and many others? But in some cases the name of this celebrated botanist has been attached to species which he has never mentioned. Thus the *Oleum Bergamii* is said to be procured from *Citrus Limetta Bergamium*, on the authority of De Candolle, although there is no species of this name in his *Prodromus*!

We are at a loss to conceive why the College has thought proper in some instances to follow De Candolle, in others to retain the old names, in

defiance of him and of other modern authorities: thus *Myrtus Pimenta* is still retained, though De Candolle, whom they profess to follow, calls it *Eugenia Pimenta*. In the *Pharmacopœia* we are told balsam of Peru, and the balsam of Tolu, are obtained from the same species, namely, *Myroxylon peruiferum*: yet De Candolle, their professed authority, distinctly says that the first of these balsams is from *M. peruiferum*, but the second from *M. toluiferum*. In some instances wrong plants have been quoted: *Lavendula spica* for *Lavendula vera*; and *Fœniculum vulgare* for *Fœniculum dulce*. The latter is a gross error, since De Candolle himself was the first to separate the *F. dulce* from the *F. vulgare*, for previously they had been regarded as varieties merely; so that it would seem the name must have been quoted in the *Pharmacopœia* without the *Prodromus* having been consulted.

There are many other errors of a less important kind, but strongly indicative of a slovenly, loose, and careless mode of getting up. Thus *Radix* is put for *Rhizoma*, under *Aspidium*; *Amyris elemifera* is printed *Amyris Elemifera*; *Castor fiber* is written for *Castor Fiber*; *Strychnos nux vomica* is put instead of *Strychnos Nux vomica*; and *Terebinthina Canadensis* for *Terebinthina canadensis*. These mistakes, though slight, ought not to have been allowed to have occurred.

In the first column of the *Materia Medica* the names of the different substances are sometimes put in the singular, sometimes in the plural number, shewing a great want of uniformity in the plan of proceeding. Thus we have *Myristica*, a nutmeg, but *Mora*, mulberries; while the syrup of the latter is called *Syrupus Mori*, syrup of a mulberry!

Chemical nomenclature.—It has been cast as a reproach on former editions of the *Pharmacopœia*, that the nomenclature employed was not in accordance with the then state of chemical knowledge; and in this edition an attempt has been made to remedy the defect. Thus in most instances the word *chloridum* has been substituted for *urias*; though in a few cases the term *hydrochloras* has been properly preferred, as in *sal ammoniac* and the *hydrochlorate of morphia*. The quondam

alkaline carbonates are now either *sesqui* or *bicarbonates*, which is all very proper. But we may here remark, that the College has fallen into an error in denominating the common magnesia of the shops a carbonate "*Magnesia alba*," says Berzelius, "is a chemical compound of carbonate and hydrate of magnesia. When we precipitate the solution of a magnesian salt by an alkaline carbonate, we ought to obtain a neutral carbonate; but the water decomposes it, so that the alkaline carbonate incompletely precipitates the earth, some bicarbonate of magnesia remaining in solution."

The nomenclature of the double salts has been altered: thus tartar emetic is now called *antimonii potassio-tartras*; the quondam, *cuprum ammoniatum* is now *cupri ammonio-sulphas*; *ferrum ammoniatum* is altered to *ferrum ammonio-chloridum*; *soda tartarizata* is termed *sodæ potassio-tartras*; and so on. In naming these substances, the College has followed the last edition of Dr. T. Thomson's "*System of Inorganic Chemistry*." But, with all due deference to the College, and to Dr. Thomson, the names are very objectionable. Let us illustrate our meaning, by reference to the preparation called in the *Pharmacopœia* the "*Ferri Potassio-Tartras*." This salt is a double tartrate; — that is, its basic or electro-positive constituent is the tartrate of potash, while its acid, or electro-negative ingredient, is the tartrate of iron. That the iron really does perform here the function of an acid, seems proved by the fact that it is not recognizable in a solution of this double salt, by either the ferrocyanuret of potassium (unless, indeed, an acid be added, to disengage the tartrate of iron), or by alkalies. Now the constitution of the salt being admitted, what ought to be its name? In the denomination of the single salts, we always put the name of the acid, or electro-negative ingredient, before that of the basic or electro-positive one: thus we say, sulphate of magnesia, not magnesiate of sulphuric acid. If the same principle be extended to the double salts, we ought to designate the above mentioned chalybeate salt, the *iron-tartrate of tartrate of potash*, which may be conveniently shortened to the *iron-tartrate of potash*, while tartar emetic

would be the *antimony-tartrate of potash*. Berzelius's nomenclature is not well adapted for our language, but it is formed precisely on the principles we are here advocating. Thus he calls soluble tartar, the "*tartrate potassique*;" the ferri potassio-tartras of the Pharmacopœia is "*tartrate ferrosi-potassique*;" and emetic tartar is "*tartrate antimonico-potassique*."

By the way, we may remark that the College has not adhered to Thomson's method of nomenclature in the case of all the double salts. Thus they describe alum as being "*sulphas aluminæ et potassæ*," whereas Thomson calls it "*potash-sulphate of alumina*." According to our notions it ought to be "*alumina-sulphate of potash*," a name which in spirit agrees with that of Berzelius, "*sulfate aluminico-potassique*."

Prussian blue is most improperly, as we conceive, termed "*Ferri Percyanidum*." In Mr. Phillips's translation, the following sentence occurs:—"Percyanide of iron, usually called Prussian blue, and sometimes Ferrosesquicyanide of iron," &c. Now any person would fancy from reading this passage, that while the vulgar name for this substance is Prussian blue, the usual and proper term is percyanide of iron, and that the phrase ferrosesquicyanide is sometimes but less properly employed. How stand the facts?

1st. Prussian blue is called in no chemical work of repute that we have consulted, percyanide of iron. On this point we have referred to the works of Thomson, Turner, Henry, Ure, Brande, Fyfe, Berzelius, Thenard, Dumas, Gay-Lussac, Lassaigne, and Gmelin. In not one of these have we met with the collegiate name of Prussian blue, even among the synonymes for this substance.

2dly. The term percyanide is incorrectly applied to it, on two grounds: the first is, that there is another compound to which this name more properly belongs; and secondly, Prussian blue is a double cyanuret. If we turn to the "*Table Synoptique*" of Berzelius, published in 1835, we find a substance is there mentioned by the name of *Cyanure ferrique* (equivalent to our term percyanide of iron), containing 59.33 per cent. of cyanogen; while Prussian blue contains only (according to Mr. Phillips)

54.4 per cent. It is true this *Cyanure ferrique* has not been obtained in the separate state, but of its existence in certain compounds, no chemist, we believe, entertains a doubt.

3dly. The term Ferrosesquicyanide (or Ferrosesquicyanuret) of iron, which we are modestly told "sometimes" occurs, is the name by which it is designated in every modern chemical work.

Præparata et composita.—For the same reasons that the College has not thought it necessary to give formulæ for the preparation of sulphuric acid, sulphate of magnesia, acetate and phosphate of soda, chlorate of potash, ferrocyanide of potassium, and many other chemicals, we think they might have left out various formulæ still retained in the Pharmacopœia. We allude now to those for making such articles as chloride of lime, hydrochloric acid, acetate of lead, tartaric acid, &c.; and others which are manufactured on a very large scale, their uses not being confined to the medical profession.

We are glad to see formulæ for the preparation of the vegetable alkalies introduced. We may remark that the production of aconitina is a delicate process, and requires a dexterous and experienced manipulator to succeed. The article sold as aconitina, made by Pelletier, is almost inert, and for remedial purposes useless.

The manufacture of the disulphate of quina without the use of spirit has long been a desideratum with chemists, which we are afraid the formula of the College will not remove. It is a modification of M. Henry's process, which did not succeed in France, and failed, as we know, in the hands of an experienced English manufacturer, in consequence of the small product obtained by it; for he found the old process in which spirit is employed to be cheaper.

The process given in the Pharmacopœia for the manufacture of the biniodide of mercury, is, in our opinion, inferior to the one usually followed—namely, the mixture of solutions of the bichloride of mercury and the iodide of potassium in atomic proportions. The product by the latter process has a much finer colour than that obtained by rubbing iodine and mercury together, as directed by the College.

The mode of procuring bromide and iodide of potassium, as given in the

Pharmacopœia, is objectionable, — a much purer article being obtained by other methods. By the College process, it is difficult to procure the iodide free from some carbonate. It is well known that a considerable portion of the iodide of potassium of commerce is largely adulterated with carbonate of potash,—frequently the latter ingredient constituting more than 70 per cent. of the so-called iodide. Now the presence of this carbonate may be instantly ascertained by pouring a little lime water over a suspected crystal placed in a wine-glass. We are surprised this test was not mentioned in the short notes introductory to the “*Præparata*.” It is true the non-solubility of the carbonate in alcohol would show the presence of some impurity by the College test, but the test we have mentioned is more simple, and can be more expeditiously applied.

Manufacturers frequently make the sesqui-carbonate of soda, and the bicarbonate of potash, not by the processes given by the College, but by boiling the sesquicarbonate of ammonia with the carbonate of soda or of potash. The process is given in the “*Pharmacopée Raisonnée*” of Henry and Guibourt, p. 409, tom. ii., and should have been noticed by the College.

There are two most absurd compounds introduced into this edition,—namely, a *compound mixture of cascarilla* (composed of infusion of cascarilla, vinegar of squills, and the compound tincture of camphor),—and the *compound mixture of gentian* (containing compound infusion of gentian, compound infusion of senna, and compound tincture of cardamoms). We presume these are the favourite prescriptions of some Fellow of the College, who wishes to save himself the trouble of writing their composition every time he orders them.

We could raise many objections to, and point out several errors in, the arrangement of the different preparations: our space, however, only permits us to notice the following:—*Tinctura ferri ammonio-chloridi* and *tinctura ferri sesquichloridi* ought to have been inserted along with the *tinctura iodinii composita* and other tincturæ: many articles have been omitted in the index; as the above-mentioned two tinctures of iron, &c.

In concluding these remarks on the

Pharmacopœia, we may add, that while there are undoubtedly many very great improvements in it, as compared with the previous edition, as a whole it has disappointed us; and we must add, that the parties who undertook to prepare it for the press have not performed their duty in a creditable manner either to themselves or to the College.

The Works of John Hunter, F.R.S.; with Notes. Edited by JAMES F. PALMER. In 4 vols. 8vo. illustrated by a volume of Plates, in 4to. Vol. I. Longman and Co.

IN our last number we briefly noticed this work, and the coincidence of its appearance with the re-opening of the Hunterian museum, and the delivery of the Hunterian oration. In our present notice we propose adverting to some particulars of the “*Life*,” but shall first call attention to the nature of the work itself.

This is not merely a reprint of Mr. Hunter's published works and miscellaneous papers, but a complete collection of all his writings, printed as well as manuscript, systematically arranged, and preceded by a new life of the author. We are informed by the editor, that nearly a volume and a half of this collection appears now for the first time in print; and that he has been enabled, chiefly through the liberality of the Royal Society in allowing him the use of their plates, to complete the entire series of illustrations, amounting to not less than sixty-three engravings, among which are many of a very costly and magnificent description. Undoubtedly the peculiarity of the work consists in the plan of grafting on the text of the author a series of annotations illustrative of the various subjects treated of—a plan which cannot fail to be generally useful, and which, in our judgment, was the only thing required in order to render Hunter a popular author. Independently, however, of this, the work was much required, and we are glad to see it presented to the profession in so accessible a form.

One circumstance cannot fail to strike every one in the least acquainted with Hunter's life, which is, that he had not only extraordinary difficulties to contend with during his life, but that, after

his death, the same difficulties seem to have conspired against his fame. More tardy and incomplete justice was never rendered to any one possessing the same claims to distinction. Nearly fifty years have elapsed since his death, and yet, until lately, his museum has never been adequately displayed, or illustrated by catalogues, his writings have never been collected, his manuscripts have been destroyed, and his life has been incompetently written;—we say incompetently written; not but that Sir Everard Home possessed the ability, as well as materials, to have done justice to the subject, but that he did not choose so to employ them. The memoir which he has left us, prefixed to the Treatise on Inflammation, is meagre in the last degree, and totally destitute of those characteristic traits of character which give interest to biography. Mr. Jesse Foot's production is a gross libel, and Dr. Adams' a fulsome and undistinguishing panegyric.

It requires no mean qualifications to become the biographer of such a man as Hunter. Praise and blame are easily dispensed, but without sufficient grounds for these verdicts the former becomes mere compliment, and the latter absolute temerity. The celebrated artist, Barry, observed, "that no portrait painter could paint a better head than his own." The mere outline of the face may be given, by any artist of mediocrity, with tolerable precision; but the man of genius only can animate his canvas with the mental character and energy of his subject; the exterior indications of deep feeling and powerful intellect being only to be perceived, felt, and expressed, by a kindred genius. We do not mean by these observations to imply that Hunter and his biographer are at all comparable, but that there is something in the composition before us which leads us to judge very favourably of the author. His subject is well arranged, his anecdotes are aptly introduced, and his style is manly and perspicuous. It is evident that he has an adequate acquaintance with comparative anatomy, as well as with medical literature, to form a correct judgment of the various subjects which come before him. He is always impartial, and in doing justice to Hunter, does no injustice to others. His characters are justly conceived and boldly drawn, and particu-

larly that of Hunter, which stands out with an individuality of form which marks the skill of the artist. In fact, the Life before us completely supplies what we wanted, and we cannot but consider it as a fortunate circumstance that it has been written while it was yet possible to rescue so many anecdotes from oblivion. A very few years more, and it would have been impossible to have written such a Life.

If it be the prominent characteristic of a superior mind to select a grand and useful object of pursuit, and to follow that object with indefatigable perseverance and well-directed toil through a long life, regardless of, or surmounting, innumerable impediments, harassed by petty enmities and jealousies, little aided by friends, interrupted by the duties of an arduous and anxious profession and by bodily diseases induced by the intensity of his exertions; little cheered by even the most candid of his scientific contemporaries, who could only dimly scan the scope of his views, and could not appreciate his ability to accomplish them; if such singleness of object and vigorous perseverance in its attainment mark the highest order of intellectual and moral energy (and the fame of Columbus is founded on these claims), no age or nation can produce a name that would be robbed of its dignity by a comparison with that of John Hunter. Taking him altogether in the combined character of a physiologist and surgeon, and contemplating him under these accumulated difficulties, we cannot but consider him as an *instantia singularis* among men, which would have marked a new era in science in any age or country in which he might have happened to have lived. That Hunter was indifferent to fame cannot be asserted, although it is probable that he was less ambitious of present renown, and especially of mere popularity, than most men of his calibre. His object, like that of his brother, Dr. William Hunter, appears to have been more remote, and to have been directed to posthumous celebrity. This probably arose from the habitual tendency of his mind to form grand conceptions, and to look forward to some remote but undefined period for their ultimate accomplishment, and partly also, it may be presumed, from a consciousness that he had outstripped the age in which he

lived, and which he therefore considered as incompetent to judge of his merits. This appears by his bequeathing his two great works (his Museum, and his work on Inflammation, the grand embodiment of his experience and labours) to posterity; trusting, in the manly confidence of his nature, that they would be justly appreciated after his death. He was not unaware of the impulse which his labours had already imparted to science, and hence he formed the conclusion that a time would soon arrive when his pretensions would be estimated as they deserved. Perhaps his eager pursuit after knowledge was of the same nature as that of some men after wealth, which leaves them no time to enjoy it. Certain it is, that he spared no pains in completing his Museum, and no labour in perfecting his work on Inflammation, although he left the one without a catalogue, and the other to be published after his death—a clear evidence of the noble kind of ambition by which he was animated.

It appears to us that Mr. Ottley has too slightly passed over that part of his subject which at first may strike us as of most importance—namely, to mark the limit to which physiological knowledge had reached at the first outset of Mr. Hunter's career, and then to trace the influence of his example and discoveries on the subsequent rapid advancement of that science; and also, that he has omitted to draw that large and ample sketch of Mr. Hunter's genius, and to institute those parallels between him and other great men, which the case seems to have required. We believe, indeed we are assured, that these defects arose from a desire to limit the memoir to a reasonable size, and not from any oversight on his part. It must be evident that such objects could not have been attained without considerable amplification, and also that much accurate research would have been necessary, in order to adjust the respective merits of physiological claimants, which could scarcely have been instituted in a provincial town. We are informed, however, that the first of these omissions will be compensated by a preliminary dissertation to the fourth volume of the present edition, from the pen of Mr. Owen, and than whom, no one in this country, or perhaps in any other, is more competent to the task;

and with regard to the second, we propose ourselves, in a future notice of the work, to endeavour to supply the deficiency.

MEDICAL GAZETTE.

Saturday, February 18, 1837.

"Licet omnibus, licet etiam mihi, dignitatem Artis Medicæ tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

COLLEGE OF SURGEONS.

HUNTERIAN ORATION.

THE re-opening of the College of Surgeons at the present moment is an event of some interest and importance to the profession generally. The building has been greatly enlarged, and in many respects better fitted for the accommodation of the great body of members. The library is a splendid room, which is to be open not only during the day, as formerly, but in the evening also three times a week. It contains 20,000 volumes, which are rendered easily accessible by the attendance of an excellent librarian, and is altogether a very important addition to the professional resources of the metropolis. But the principal improvement relates to the museum, to which a much more extended space is allotted; and many preparations which have long been buried in dust and cobwebs are once more permitted to "revisit the glimpses of the moon," or rather of the meridian sun, in which, thanks to the labours of Mr. Clift and Mr. Owen, they now shew to great advantage. The pathological portion of the collection is separated from the physiological, and the facilities of study are thus greatly increased. But still more important is the advance made in the Herculean labour of constructing a catalogue *raisonnée*, which, in conjunction with the lectures about to

be delivered by Mr. Owen, in illustration of the museum, will give a practical value to the possession of this magnificent collection far greater than any which has hitherto been derived from it.

Under any circumstances, then, the re-opening of the College, with such prospects, would have been an event of interest, but it has been rendered doubly so by the changes which have taken place during the interval of its temporary closure. It is evident that if the present government endure for but a few years, a struggle must take place between the present institutions and the rival one which is in embryo—the new University, in which the tripartite faculty of physic, surgery, and pharmacy, is to be attempted, not in conjunction with the present Colleges and the Worshipful Society, but in direct opposition to them; so that the old or the new must necessarily fall.

Of the existing institutions connected with the medical profession, the College of Surgeons is in various respects by far the most important. The building is worthy of a great national establishment; the library is a magnificent addition, which has grown up of late years; the museum is a monument worthy of the name it bears, and creditable to the nation. Nor do the names of many among its present members reflect less honour upon English surgery than the greatest of their predecessors; while of the existing Council it is but justice to add, that they have shewn their determination to keep pace with the march of intellect and the improvements of the times. In these respects—we mean in setting aside ancient prejudices—in gathering wisdom from passing events—and in rendering their institution available to great national objects—we must say they have far outstript

their elder brethren in Pall Mall, and accordingly are their character and influence as a public body proportionally greater. It is in Lincoln's Inn Fields that the battle between the new and old race of practitioners must be fought; and if we may judge from the number of members, and from the nature of the feelings manifested on Tuesday last, he will be a bold man who leads the forlorn hope in storming their citadel.

But it was our intention merely to have given some account of the proceedings of Tuesday; and to these we now turn. Never, probably, since the oration sacred to the genius of Hunter was first instituted, has it excited more general interest; indeed, the crowd was so great, that many were unable to procure admission; but this was unavoidable, as the members of the College are now so numerous that it is quite impossible for all of them to be accommodated at once. We understand, however, that by placing additional benches, and other arrangements, what in the language of the theatres is called "sitting-room," had been provided for considerably more than 500 persons.

Among those present were the Duke of Wellington, Sir Robert Peel, Lord Stanley, the Bishop of London, the Lord Chief Justice Denman, the President and Censors of the College of Physicians, the Director-General of the Army Medical Department, the Physician-General of the Navy, and many other distinguished visitors. On the entrance of Sir Robert Peel, the whole company rose and cheered him in the most enthusiastic manner, and a like compliment was paid to the Duke of Wellington, on his entering the theatre immediately afterwards. The same animating scene was repeated on their leaving the room after the oration was concluded; and nothing could possibly ex-

ceed the warmth of the reception with which the presence of those distinguished statesmen was hailed.

On the orator of the day (Sir Benjamin Brodie) entering, he was greeted in a manner that must have been most gratifying to him—such, indeed, as the most callous man must have felt as a willing tribute of cordial and friendly feelings, on the part of the immense body of his professional brethren assembled on the occasion. Before commencing the oration, he stated that Sir Astley Cooper had been prevented, by sudden illness, from taking the chair as President; and the manner in which the compliment which he took the opportunity of paying to the character of his distinguished compeer, as “the greatest of English surgeons,” was received, showed how true is the sentiment that *laudari a laudato viro* is the highest tribute which merit can receive.

The oration was very interesting. It began with an allusion to the two friends, William Cullen and William Hunter, leaving the obscure village which was the field of their early career, to become pre-eminent in the capitals of Scotland and of England. The progress of John Hunter, “the raw uncouth Scotch lad,” from the idle habits of his boyhood till he became the most industrious student and greatest philosopher since the days of Newton, was next rapidly sketched, and interspersed with numerous anecdotes and illustrations. The labours of Hewson, Cruikshank, Baillie, and Home, were next successively spoken of. To Baillie the orator gave just and warm praise for his sagacity and skill, but above all for his surpassing disinterestedness, his entire *abandonnement de soi* in all his professional conduct. To Home, too, he hesitated not (despite the “shade” which certain transactions of his latter years have cast upon his memory) to give

the meed of praise which was due to some parts of his professional character. Lastly, he spoke of Sir William Blizard, whose habits and disposition he portrayed as those of chivalrous simplicity, and a conscientious but mistaken love for all that belonged to a former age.

Sir Benjamin concluded by some appropriate remarks addressed to the younger portion of his audience; but neither of these, nor of any part of the address, do we give more than a mere notice, because we understand that it will be published—when we shall have an opportunity of bringing it before our readers in a correct form. The oration was frequently interrupted by applause, and the whole scene was one which could not fail to be very gratifying to the friends of the College; while it must have been gall and wormwood to those who for the last three or four weeks have been labouring to produce a very different result.

THE LATE M. DESGENETTES.

THIS distinguished veteran died at Paris, on the 4th instant, after a long and painful illness. A deputation from the Academy of Medicine attended his funeral, on which occasion several complimentary discourses were pronounced over his grave, according to the French fashion of doing honour to the dead. One of these eulogies was heard to proceed from the “*voix enchantée*” (as the Gazette des Hôpitaux has it) of M. Pariset, another from the “*noble et robuste organe*” of M. Broussais, and the third was marked “*par l'éloquent mâle*” of M. Bouillaud.

In M. Desgenettes the French have lost one of the most illustrious ornaments of their medicine and their military renown. His name has long been distinguished in the page of history: it was widely known, and was popular in Egypt, in Syria, in Spain, in Russia, as well as in France.

With a higher and better feeling than

Hippocrates, as some of his panegyrists have said, he bestowed his professional care indiscriminately on the sick of all nations; on the Turk as well as the Christian—on the inhabitants of the north as well as of the south.

The tact with which he treated the moral as well as the physical evils incident to suffering human nature, was well exemplified by his memorable proceeding in Egypt. He there adopted a remedy for the plague, which acted as if by enchantment. The soldiers had become panic-struck on the appearance of the pestilential malady among them—their mental depression was extreme. The mortality was tremendous, and raged precisely in proportion to the despair which seized the victims. What was to be done? How was confidence to be inspired? The thought struck Desgenettes that there was but one way of safety. He went among the troops, and assured them that those hideous buboes were not infectious; and in proof of this, in the presence of the French army, inoculated himself with the plague. It was a daring expedient: rash and desperate, without being decisive; but it was the salvation of the soldiers. Their courage was restored, and the mortality immediately diminished.

The noble part which he played in Syria did him still greater honour. He refused to obey the inhuman mandate of Buonaparte, who sought by his means to rid himself of the sick at Jaffa. It was suggested that they should be despatched with opium. "My art teaches me to save men, not to destroy them," was the heroic answer of Desgenettes; nor does his boldness seem to have lost him the favour of his master. For five and twenty years he was confidentially engaged about the person of Napoleon: from the rise of the victor in Italy to his setting at Waterloo, Desgenettes was with him in all his campaigns.

In the memorable retreat from Russia, Desgenettes was made prisoner; but he proudly demanded his liberty, "not as a boon, but as a right;" he appealed to the character of his profession, and in particular to the care which he had bestowed indifferently on Russians as well as Frenchmen. An imperial ukase soon set him free. The Emperor Alexander made a special communication to him, and expressed the high esteem which he enter-

tained for his character. The King of Sweden shortly after sent him the order of the Polar star.

A similar tribute, it will be recollected, was paid to the merit of Baron Larrey, at Waterloo. This eminent surgeon, and distinguished *confrère* of Desgenettes, was taken prisoner by the English in the retreat after the battle; but he soon obtained his liberty through the same honourable feeling: he had been indefatigable in exerting his professional services in behalf of both English and French.

Desgenettes was born at Alençon, in 1762, and educated chiefly at Paris. He visited this country about the year 1785, and enjoyed the friendship of Sir Samuel Romilly, Sir Joseph Banks, and all the eminent persons of the day. Mirabeau was in England at the same time, and it was here that Desgenettes made his acquaintance. After this he travelled a good deal in Italy, but returned in 1789, and graduated doctor in medicine at Montpellier. In 1793 he obtained an appointment in the Army of Italy; and during the subsequent campaigns of Egypt and Syria was raised to the rank of Physician-General (*Médecin en chef*.) The professorship of *Physique médicale et d'Hygiène*, in the Faculty of Paris, was bestowed on him in 1799. In the sweeping changes made in the professorships under the Frassinous administration, in 1822, Desgenettes, along with Chaussier, Dubois, Pinel, and Vauquelin, were ousted from their chairs; but Desgenettes was reinstated some years since, and retained the office till his death.

The character of his mind was that of sterling good sense and sagacity. His sturdy independence and liberality of sentiment were also generally appreciated. As a teacher, he was clear and systematic; and his lectures abounded with original and striking views. As a speaker, his manner was familiar, and to the point; in discussion, particularly in the Academy of Medicine, he has always displayed a ready command of reasoning power, combined with an animated elocution.

He wrote several things; such as the Analysis of the Absorbent and Lymphatic System, and his Medical History of the Army of the East; but his life was rather spent in action than in study, although the business of the camp did not prevent him from reading

much, and of gathering from books a solid erudition, which he always knew how to use with discrimination.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, February 14, 1837.

MR. EARLE, PRESIDENT, IN THE CHAIR.

THERE were three papers read this evening. The first was—

On the Constitutional Treatment of Exostosis with Mercury; conjointly written by F. C. SKEY, Esq., Assistant-Surgeon to St. Bartholomew's Hospital, and Dr. BOSTOCK, F.R.S.

The author (Mr. Skey) detailed the particulars of a case under his care in St. Bartholomew's Hospital, which had been treated by mercurial inunction. The disease occupied the upper part of one humerus, where it formed a considerable tumor, and likewise the region of each knee, bony growths being apparent from both femur and tibia. The subject was a young woman, in every other respect apparently healthy. The author stated that the tumor had progressed very apparently up to the period of his application of the above treatment, from which date the bony enlargements ceased to extend, and that by perseverance in the remedy there was some reason to hope that a positive diminution in the general mass of the diseased growth had occurred. This he inferred from the cessation of a degree of numbness in the hand of the affected limb, which had been occasioned by the pressure of the tumor on the brachial nerves, below the axilla. Mr. S. also stated that the treatment of exostoses by mercury was not new, and that he had employed it without any sanguine hope of advantage to be derived from it; he had resorted to it, not with the view to obtain absorption by its local application to each tumor, but by its general influence on the arterial system.

During the treatment of the above case, the urine of the patient was analysed by Dr. Bostock, and was found to deviate far from the standard of health. It appeared from the interesting statement of Dr. B., that the specific gravity of the urine was, on his first examination, as low as 1005, (we understood) and that it was deficient in phosphatic salts, and in general solid contents, prior to the treatment by mercury, and that it approached the healthy standard, containing more solid matter, and rising in specific gravity, as the patient's constitution became influenced by the remedy. When the applica-

tion of the medicine was suspended, the urine again relapsed into its morbid state, and again improved when the mercurial inunction was resorted to. Dr. B. was not aware whether this condition of urine was a general attendant on the formation of the disease under consideration, but that under all circumstances it would form an interesting subject for inquiry, and for chemical investigation.

Mr. B. PHILLIPS wished to know whether the exostosis mentioned in the case might not possibly be connected with a syphilitic taint in the system, which would account, perhaps, for the efficacy of the mercury.

The PRESIDENT said, that in the absence of Mr. Skey, he would answer the question which had just been asked, and with the less hesitation, as the case had originally been under his own care. The patient, he was confident, was free from any venereal taint; she was a strictly virtuous young woman, and, he had no doubt, was perfectly pure and chaste. He could add also, with regard to the apparent malignity of the disease, that he and his colleagues, at St. Bartholomew's, were unanimous as to the propriety of operating for removal of the exostosis, and only awaited the permission of the girl and her parents to carry the operation, should it prove necessary, to the extent even of disarticulating the shoulder. About this time, however, the dresser who had charge of the case discovered that there were other similar tumors in divers parts of the body; upon which the idea of employing the knife was abandoned. It was then that Mr. Skey came into possession of the case, and treated it with so much success. He (Mr. Earle) thought the observations on the urine were very judicious and valuable.

Mr. ARNOTT protested against the supposition that it was a new thing to use mercury successfully in non-syphilitic exostosis. For his part, he had been in the habit, for some time, of noticing the practice in his lectures, and was familiarly acquainted for years with the imputed efficacy of the remedy. He had even seen cases cured in this manner; but he added (in reply to a question from Mr. Earle), that no observation had been made as to changes in the urine.

Dr. COPLAND was surprised that there should be any doubt as to the alleged efficacy of mercury in cases where there was no venereal taint. There was certainly no novelty in the practice; it was at least as old as the time of Van Swieten, who used to give corrosive sublimate, in a tonic tincture or mixture, for the discussion of tumors of the bones. He (Dr. C.), however, was not very sanguine as to the

certain success of such treatment. He had at present under his care a lady, having an exostosis, the size of a walnut, on the os frontis, and neither mercury nor iodine had any effect upon it. As to the changes produced in the urine, in Mr. Skey's case, he could not but withhold his assent to the supposition that they originated in the medicine merely, until he should be fully informed as to the nature of the ingesta, in the shape of food and drink, taken daily by the patient; also as to the time of day at which the urine was voided, and in what quantity it was passed.

Dr. WEATHERHEAD also expressed some doubts as to the changes said to have been effected in the urine.

After this, a short paper on a *Case of Osteosarcoma*, by Mr. LAWRENCE, was read; but no discussion followed.

And in conclusion, an *anonymous* paper was introduced to the notice of the Society. The author, it appeared, was anxious to have it read, but discreetly declined giving his name.

The PRESIDENT put it to the meeting whether they would permit the paper to be read. It was unusual to bring forward anonymous communications; but the Secretary, Mr. Partridge, had been entrusted with the author's name in confidence.

Leave being granted, the paper proved to be a lengthy and very stupid essay *On Small-Pox*, in which the notable idea was started, that in the disease in question there is great excitability of the system, but the remedy is in our power,—small doses (homoeopathic?) of tartarized antimony! The announcement of this fact (which constituted the substance of what the author had to say, was given in so prosy and verbose a form, that the patience of the hearers was soon exhausted, and many left the room.

ROYAL INSTITUTION.

Friday, Feb. 14, 1857.

Dr. Ritchie on the Theory of Sound.

SOME expectations were raised that this would be an interesting lecture: the subject seemed to promise favorably, and an account of new facts and experiments was anticipated. But we must say that Dr. Ritchie made any thing but a popular lecture of it: he began by announcing Newton's theory of the propagation of sound, and then went on at the annals of eminent philosophers, Euler, Laplace, Herschell, &c., who were supposed to treat

theory. He, Dr. Ritchie, considered the Newton was right, and all the other wrong; and accordingly undertook to defend the Newtonian hypothesis, and refused that of the anti-Newtonians forthwith. But what with the needless display of mathematical symbols, chiefly from the integral calculus, and the eternal reference to the chalk and black board, with which the Dr. is so familiar, the audience were far more confused in their ideas of the subject at the end of the hour than at the beginning of it. We have no idea of attempting to give an analysis of Dr. R.'s views; it were a hopeless task, and probably as useless as hopeless. Common sense surely ought to have dictated to any lecturer how such a subject as the velocity of sound might be made both interesting and instructive to a mixed assemblage: we say nothing of the ladies, who evidently expected something of a musical treat.

TREATMENT OF HERNIA.

HERNIA is of such frequent occurrence, that every hint for its palliative or curative treatment deserves to be promulgated. The application of cupping-glasses, or dry-cupping, to facilitate the taxis, has been recommended. How this application acts has not been ascertained; it is said to be most serviceable when the hernia is small, the cupping-glass being large enough to cover the tumor; but the treatment has been had recourse to with good effect even in large herniæ. The plan of Gerdy for radically curing diseases of this class has been tried with fresh modifications by several surgeons, and is represented to have answered well in small herniæ: experiments have likewise been made by Belmas, in support of the same practice. The most recent proposal for the radical cure of hernia is the employment of a firm wooden block in the place of the usual soft pad, with the truss; and a most excellent report upon the subject has been drawn up by Dr. Russell Carter and other American surgeons. In reference to operations in this branch of pathology, it seems to me to be curious, that a period and a half of profitable attention has been consumed; the very latest use of a complicated surgical apparatus has been after exposure and reduction of the hernia; the subsequent use of a novel rupture removed by ligature, is more than one instance, after Bonnet's method. All that is now done is to remove the truss. A hernia formed solely of the spermatic cord, which was found enlarged to four times its natural bulk, produced some of the most signs of strangulation, and required the operation. — *Mr. Carter's Transatlantic Address.*

R. S. COOPER AND MR. LISTON.

in consequence of a letter in the *Lancet* last week, representing it to be the wish of the students at University College that Mr. Liston should be associated with Mr. S. Cooper in the Chair of Surgery, a meeting of the gentlemen attending the lectures alluded to took place on the 15th, at which a resolution denying the truth of the assertions, and strongly disapproving of the sentiments expressed by the anonymous advocate of Mr. Liston, was unanimously passed.

Mr. Cooper's theatre on Wednesday evening was crowded to overflowing, and he was received in such manner as to shew that he had lost none of his well deserved popularity. From the nature of the address which he made at the close of his lecture to the assembled students, it is quite clear that the plan of forcing a colleague upon him has no chance of success. To use his own words, the chair is not large enough to hold them both, and—if Mr. Liston once got into it, there would be no room for him.

**PROFESSORSHIP OF ZOOLOGY
IN KING'S COLLEGE.**

Mr. RENNIE having been under the necessity of resigning the professorship of Zoology, Mr. Thomas Bell, the distinguished naturalist, has been appointed to the vacated chair. This is decidedly a good hit on the part of the College.

THE LATE DR. E. TURNER.

We regret to announce the death of Dr Turner, Professor of Chemistry in University College. A more able teacher, or one of higher character as a chemist, will not readily be found as a successor. He had been in a declining state for a considerable time. His funeral, which is to take place this day, at the Kensal Green Cemetery, Harrow Road, will be attended, we understand, by a procession of the students.

APOTHECARIES' HALL.

**LIST OF GENTLEMEN WHO HAVE RECEIVED
CERTIFICATES.**

February 16, 1837.

Richard Gardiner Jay, Badley, Suffolk.
Thomas Neats Moody, Woolwich.
John Morgan, Bath.
James George Tatem, High Wycombe, Bucks.

George Jones, Birmingham.
George Evan Evans, Fiverton.
James Probert, Lydbrook, Gloucestershire.
Edward William Holland, Emsworth, Hants.
Arthur William Franklin, Wincanton, Somerset.
Thomas Blanchard, Sunderland.

LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE XXII.

INFANTICIDE concluded. *Summary of the signs of respiration and non-respiration—2. Whether the infant died a natural or a violent death?—Appearances indicative of Natural Death—Diseases of the new-born child, congenital and acquired—Atelectasis—Signs of Violent Death—Strangulation—Suffocation—Drowning—Fractures of the Skull—may occur accidentally at birth—or during uterine life—Cases in illustration—Wringing the neck—Wounds, whether inflicted before or after death—Detruncation—Burning—Poisoning.—Question of death from omitting to tie the funis—Exposure—Conclusion, with a summary of the signs of Natural and Violent Death.*

In the last lecture I completed my review of the tests by which the fact of respiration or non-respiration is usually ascertained. Before proceeding to the second important question involved in inquiries respecting infanticide, it will perhaps be useful to sum up, in a general way, the signs by which we are led to conclude whether or not the infant ever breathed, or, if the former, whether respiration took place perfectly or imperfectly. This enumeration of the signs cannot fail to revive your recollection of the several tests, and the modes of applying them.

Signs of non-respiration.—The appearances of uterine putridity would of course be decisive; but putting these out of the question, and taking the more ordinary circumstances occurring in practice for

our data, we conclude that an infant has not respired,

1. When the form of the chest is flattish and contracted;

2. When the lungs are seen to occupy but a small portion of the chest, and the diaphragm is remarkably convex;

3. When the colour of the lungs is a dark liver tint, and their texture dense and compact, with sharp edges;

4. When the lungs are not above a fiftieth of the weight of the body;

5. When, immersed in water, wholly and in part, they sink—not being putrid, or diseased; facts which observation can readily determine;

6. When the foramen ovale of the heart, and the arterial duct, have evidently undergone no change—the latter being cylindrical in shape, and in calibre nearly equalling the pulmonary artery; and

7. When, in addition, there are none of those signs present which would indicate some continuance of life after birth—such as incipient inflammation about the root of the umbilical cord, or the intestines void of meconium.

Signs of respiration.—The case is clear where those signs are present which obviously show that life subsisted for some hours, and consequently that breathing must have been established; but we should say, with confidence, that an infant has respired—

1. When the chest is full, and arched externally;

2. When, on opening the chest, the diaphragm is not strikingly convex, but the lungs are voluminous, of a bright red or pinkish colour, and crepitous to the touch;

3. When the lungs, heart, and thymus, taken together, swim in water, and all the fragments of the lungs float, even though strongly compressed by the fingers under water, and persist in floating, though reduced to the minutest fragments;

4. When the arterial duct appears to be

diminished in size, and perhaps altered in shape, being conical towards the aorta; and

5. When, in addition, the meconium is found to have been expelled, and certain changes have begun about the umbilicus, conclusive of the fact of some survival of the birth.

Signs of partial respiration.—Unless there be reason to believe that the lungs have been artificially inflated, we may infer that an infant has partially or imperfectly breathed, from the following circumstances:—

1. That the lungs are but partially expanded, not filling as much space as they usually occupy in the chest;

2. That the colour of the lungs is not uniform, part being of a dark red or chocolate hue, and part of a lighter or pinkish tint; the latter portions at the same time vesicular and crepitous, while the former are dense;

3. That at least *some* portions of the lungs float in water, though strongly compressed between the fingers previous to their immersion;

4. That the arterial duct is found to be somewhat altered, at least in shape, if not in size;

5. And that there is no marked appearance of any vital process having begun about the root of the umbilical cord.

So much for the proofs of live birth required on trials for infanticide. We shall now proceed to the second and more especial inquiry connected with our subject,—

2. *Did the Infant die a natural or a violent Death?*

Supposing the fact of respiration, or of live-birth, to be determined, there still remains a most material question to be decided—namely, whether the infant's death resulted from violence? Unless this can be established in the affirmative, the charge of infanticide must be held to be unfounded.

(A.) *Question of Natural Death.*

Humanity suggests that before entering on an investigation of the proofs of murder, we should first be satisfied as to whether the infant might not have died a natural death.

There will, of course, be a strong presumption in favour of this supposition, when there is a total absence of marks of violence on the body. But such a conclusion ought to be founded on a strict and minute search: for wounds of a deadly kind have sometimes been so ingeniously inflicted as to escape discovery on a moderately careful examination: of this, however, we shall have something further to say presently.

1. *From feebleness.*—The infant may have perished from feebleness. The labour may have been tedious and severe, and the child, consequently, though born alive, may have sunk through exhaustion. Of the probability of this, we must judge from the circumstances. Are there marks of a difficult birth on the infant?—the allegation of a tedious labour is admissible. Does the infant, judging from principles already laid down, appear to have been immature?—the plea that it perished through exhaustion and debility is a fair and may be a valid one.

2. *From congenital disease.*—An infant in the womb may labour under certain diseases, which possibly may become aggravated at birth, and cause death soon after. Where this is supposed to be the case, the medico-legal examiner must exercise his skill in appreciating the morbid appearances which may be present: and he will not only have to satisfy himself of the actual presence of disease, but of disease arrived at such a height as to occasion death. We shall briefly notice the chief maladies found to affect the new-born infant.

(a.) *In the head.*—*Hydrocephalus* may exist in different degrees of intensity: the fluid may be simply effused into the cavity of the arachnoid membrane, without influencing in any manner the substance of the brain itself: or, in addition to the effusion into the arachnoid, some may have made its way into the ventricles; in either of these cases life is not necessarily compromised; the infant, unless there be some other obstacle to its surviving, or the lymph poured out be present in very large quantity, can scarcely be supposed to perish immediately after birth, from either of these causes. But suppose the quantity and quality of the serous fluid such as manifestly to have interfered with the development of the brain,—this must be equivalent to an incapacity to live, and in the absence of signs of violence may be considered as having led to natural death. In its ordinary state the infant brain is very soft, and the white substance is comparatively more vascular, or richly supplied with blood-vessels, than in the adult. This fact is worth remembering in medico-legal examinations. A *morbid softness* of the infant brain is characterized by an almost semi-fluid condition of the parts, of a yellowish, sometimes a blood-stained colour, and having a foetid odour, resembling that of sulphuretted hydrogen. The same sort of softening is sometimes observed in the spinal marrow: and this state is generally accompanied by extensive marks of disease in other organs of the body.

(b.) *In the Lungs.*—When mentioning the

s sometimes urged to the hydro-
t, the existence of certain diseases
ngs was alluded to. There may
as found in those organs in a con-
advanced state: but this will
nstitute a cause of death soon
h. Not so with engorgement of the
in infant, to all appearance, may
formed in every respect, and ma-
rn: yet it dies immediately after
ough the delivery may have been
he lungs will here most probably
l very voluminous, but gorged
colourless serous fluid preventing
on. Sometimes the lungs are,
r in part, filled with sanguineous
ey are generally at the same time
nd of a granular texture.

ation of the lungs is not uncom-
new-born infants: it is supposed
e result of inflammation during
life. The pulmonary tissue is
compact, heavy, sinking speedily
and not imparting any consider-
our to that fluid when left im-
n it. In short, the lung in this
strongly resembles the liver: nor
eneral difficult to distinguish such
f the organ from its natural state,
fore or after respiration.

is a disease described by Dr. E.
Leipzig, which it is important here
. It is a morbid condition of the
f new-born infants which may
their speedy death. It results
: imperfect manner in which re-
is performed after birth, a part
he lungs being filled with air, the
g part sloughing or becoming he-
or otherwise diseased. This state
ngs Dr. Jörg has denominated
(from ἀτελής, *incomplete*, and
extension or expansion); and he con-
to originate in the too rapid and
ivery of the mother. It is the
of this physician, that a slow and
fficult labour is a process salutary
o the child; that during the suc-
tages the foetus is gradually de-
f its dependence on the placenta,
when ultimately sent into the
is in a state nearly resembling
sphyxia in the adult, and is thus
powerful necessity to breathe.
, in other respects of a healthy ap-
, are often observed to be weak and
able after what is commonly called
labour; their extremities hang flac-
powerless, and their cry (if they
l) is feeble and whimpering. Such
ometimes perish, notwithstanding
forts that may be made to revive
nd the lungs are then found in
vocal condition just now alluded

Without entering into any discussion of
the physiology or pathology of Dr. Jörg,
I have no hesitation in giving full credit
to the correctness of his observations. To
the medical jurist it is obviously of great
importance that the symptoms and ap-
pearances of atelectasis should be readily
recognized when present; for they not
only indicate imperfect respiration, but in
many instances *non-viability*, or incapacity
for continuing to live—a condition in
which no proofs of infanticide, short of
the most direct and conclusive, should be
sufficient to sustain the charge.

It is worth remarking, that the mucous
membrane of the trachea and bronchia
is often found red in new-born infants,
that the pleura is occasionally injected,
and the pericardium not unfrequently
contains a lemon-coloured serum.

(c.) *In the Abdomen.*—The stomach and
intestines, as well as the œsophagus, some-
times present appearances which betoken
the existence of disease anterior to birth.
Certain marks of inflammation in the
œsophagus might even be mistaken for the
effects of a ligature applied externally
before death, were there other reasons for
suspecting that strangulation were at-
tempted. In the stomach, also, it deserves
to be noted, ulcerations have been observ-
ed, attended with ruddy or dark-coloured
discharges, which might easily give rise
to suspicion of poisoning.

Such are the principal morbid appear-
ances which might induce the medical ex-
aminer to form an opinion relative to the
probable occurrence of natural death. It
is scarcely necessary to add how much it
behoves him to be scrupulous in his infe-
rences, and to recollect that his pathologi-
cal inquiries may be the means of saving
the life of the accused. We now come to
consider the

(B.) *Question of Violence.*

There are many ways of destroying the
new-born infant; yet the methods usually
adopted are not numerous, the deliberate
murderer generally taking care to leave as
few marks of injury as possible. The
mode most commonly had recourse to
is—

Strangulation.—It will be kept in mind,
that in considering the question of violence
offered to the new-born infant, we suppose
the fact of respiration already established,
and that the child had begun to have an
independent existence. The signs, there-
fore, of the present mode of death must be
expected to resemble those indicative of
strangulation in the adult, but of course
in a less strongly marked form, in conse-
quence of the diminutive size of the parts
affected. It were premature here to give
a detailed description of the appearances
characteristic of death by strangulation:

where the compression has been greatest—that is, in the farthest situation; whereas, anterior to this, it is red or violet-coloured, thickened, and swollen.

Drowning in the discharges, or other fluids, may be recognized by the ordinary signs of death by drowning, together with the peculiar appearance of the contents of the mouth, gullet, stomach, and air-passages.

It is not necessary that we should here enter into a detail of the signs of death by drowning: the discussion of that subject will be more appropriately entered upon hereafter. Let it suffice at present, that on dissection the lungs and right side of the heart are generally found full of blood, the brain will probably be congested, and in the air-passages a watery froth will be perceived. This last sign is not always present; but when it is, it indicates unquestionably the fact of death by submersion. Also the presence of fluid in the stomach, of the same kind as that in which the body has been found, is a strong proof that deglutition was effected, and therefore that the infant was still living when submerged.

Fractures, blows, and wounds.—Infants have frequently been found with extensive fractures of the skull, such as to raise the strongest possible suspicion that murderous violence had been employed. But in such cases it has commonly been alleged that the fractures were the result of accidental injury—the child, for example, having been expelled from the mother by a sudden labour pain. The late M. Chaussier made a series of experiments to determine whether falls of this description were capable of causing the serious injuries referred to. Fifteen still-born children were allowed to fall perpendicularly, and head foremost, from a height of eighteen inches, on a paved floor. In twelve of them one or other of the parietal bones was broken. When the height was three feet and upwards, the fractures were proportionably greater.

In an interesting trial for infanticide which took place at New York a few years since,* the principal question was, whether a severe fracture of the skull, causing the death of the child, might not have occurred accidentally at delivery. The accused was a young woman of colour, who endeavoured to conceal the fact of her having given birth to a child: but its body was soon found. “The body,” as was stated in the evidence at the inquest, “was that of a full-grown male child, which had breathed, and no external marks of violence were visible about it, excepting some effusion

of blood, partly fluid and partly coagulated, under the scalp covering the frontal bones. The parietal bones were both fractured, the left in three places, (fig. 31, 1, 3, 4.)

FIG. 31.

radiating from a central point, the right in one (2) which was evidently a continuation of the middle fracture crossing the vertex.” Opinions were divided as to the manner in which this injury was produced; one or two of the medical witnesses thought that it was the result of a blow inflicted with a stick or some hard substance, but admitted the possibility of its being caused by a fall from the mother on the frozen ground. Others testified to the probable truth of the prisoner’s statement, that she was delivered suddenly, standing in the barn yard, and that the child dropped from her on the frozen gravelly soil: the fractures, too, it was argued, were in the very place where we might expect to find them, had they resulted from such an accident. The court and jury seemed to be satisfied with this view of the case, and the prisoner was acquitted.

Thus it would seem to be satisfactorily shown that, in sudden labours, fatal injury may befall the child from the accident of its dropping from the mother. But it should be mentioned that experience does not always warrant this conclusion. Dr. Klein, just now quoted, availed himself of the opportunity he possessed, by his official station in the kingdom of Wirtemberg, to procure returns of all such labours occurring within his jurisdiction. The result was, 183 well authenticated cases, in 150 of which the mothers were suddenly delivered standing; yet there was not a single case of death among them, nor of fracture of the skull, or other mischief happening to the infant; though some of the children had fallen on bare boards, and some on the *paré*. The reason of the difference between the experiments and those cases occurring in nature is supposed to be, that in the latter the direction in which the body of the infant is projected is oblique, and

* American Journal of Med. Sciences, Feb. 1836; and Med. Gaz., vol. xviii. p. 44.

the fall is not so instantaneous as in the experimental essay. We cannot, however, deny the *possibility* of fracture thus occurring during a natural labour.

In connexion with this subject it ought to be mentioned, that M. Chaussier made some further observations, to show the difference between fractures caused by accidental falls, or during labour, and those produced by violence. The chief differences are, that where wilful violence has been employed, the injuries will most likely be found much more numerous and extensive—for the murderer generally goes on striking till the child expires; and fractures and bruises in this case will commonly be found in parts of the head where the accidents alluded to could not possibly produce them: for example, the bones of the face may be found fractured, or the frontal and occipital bones, or even the base of the skull itself.

I have alluded to the possibility of fractures of the head occurring *during labour*. It should be stated, that there is authority for asserting that such fractures may be caused by pressure, or by the violent contraction of the uterus during parturition; nay, there are well-authenticated cases on record, of children coming into the world with fractures of the skull, which must have happened *during uterine life*. In an able essay recently published by Dr. Schwörer, professor of midwifery at Freiburg*, we have an account of nine such cases, eight of them happening within the experience of Schmitt, Jörg, Siebold, and others; the ninth in the author's own practice. Schmitt met with two cases; the first was one in which, from the fall of a drunken husband, his head striking the belly of his wife four weeks before delivery, the skull of the fœtus was fractured: the child was born alive notwithstanding, though it soon died; but, as Dr. Schmitt observes, had it been born elsewhere than in the Lying-in Hospital, or under circumstances of concealment, the suspicion might have been readily formed that it was destroyed deliberately. In Schmitt's second case, the left parietal bone was fractured during labour, in consequence of the arm coming down while the head was being expelled. Meissner relates a case which happened in Jörg's clinique, where two fissures of the skull were occasioned during labour; and in Siebold's practice the left parietal was severely fractured, the labour being extremely difficult, attended with convulsions, without any possibility of employing instruments. In the case which occurred to Dr. Schwörer, and which gave rise to his clever dis-

sertation, the woman was delivered by the efforts of nature alone, in the Lying-in Hospital of Freiburg. She was subject to hysterical fits, and about four weeks before labour had a fall out of bed during a paroxysm: to this accident the injury found on the child's head at birth was attributed. A large ecchymosis was observed over the right parietal bone, corresponding to a fracture in the part to the extent of about an inch. The child never breathed, though its movements shewed that it was alive at birth.

There is a species of violence which kills an infant at once, and yet may elude the observation of a moderately diligent examiner; namely, the effect of *twisting the head on the vertebral column*. Here there would probably be not the slightest external mark to engage the attention of the medical jurist, nor would the loose moveable condition of the neck form any better guide,—for this is common to all new-born children, especially when the weather is not very cold. The only practical caution that can be given on this point is, that an opportunity of inspecting the internal state of the upper part of the neck ought never to be neglected.

The *wounds* inflicted on the new-born infant, for murderous purposes, are generally confined to the head and neck. Punctures, however, of the heart have been detected, as well as similar injuries done to the head. The story in the *Caus célèbres* of the diabolical French midwife, who used to despatch her victims by thrusting a long needle into the fontanelle as soon as it presented, is well known. In cases of detected puncture, the wound should be carefully traced in all its extent, when it will be generally found that it widens as it departs from the surface, the murderer employing a rotatory motion of the instrument, the more effectually to accomplish the purpose intended.

A very important inquiry respecting blows and wounds is, whether they were inflicted before or after death; nor must it be denied, that there is considerable difficulty, if not an utter impossibility, to decide the question—when, especially, there is reason to suppose that the injuries were inflicted *soon* after death; for then there will be little or no appreciable difference between such injuries and those done a short time *before*. But suppose the wounds produced some hours before death, there ought then certainly to be decided appearances present; swelling and redness, for instance,—and still more marked phenomena, if the injuries were of longer standing.

Another point worth attending to is, to ascertain by what sort of weapon, or in-

* Beiträge zur Lehre von dem Thatbestande des Kindermordes überhaupt, und den ungewissen Todesarten neugeborner Kinder insbesondere. Von Dr. J. Schwörer. Freiburg, 1836.

strument, the wound was made; the form, length, breadth, and depth of each wound should be carefully examined; likewise whether its edges are smooth, or lacerated, or bruised. Too much care, indeed, can scarcely be bestowed on the examination of wounds.

Detruncation and burning.—Deeds of violence of this nature are usually perpetrated for the purpose of conveniently getting rid of the body of the infant. It may be urged that such methods were taken with the simple object of concealment, the child having been born dead. The question then is, can we say whether the body was thus treated anterior or subsequent to death?

Proofs of death by *detruncation* can only be ascertained on the principles which apply to wounds generally: the signs will be the more manifest the more tedious the process employed, and the more early begun before dissolution.

Of death by *burning* we are better supplied with the means of proof. Experiment and observation show that the appearances of burns, as inflicted before death and after, are very characteristically distinct. After death, the application of fire, or red-hot irons, merely chars the part; and if vesicles be produced, they are filled only with air, unless the subject be dropsical or anasarous, when they may contain fluid. But when burns are effected before life is extinct, decided marks of vital reaction are observable; a blush of redness forms round the part in a few seconds, which, though not wholly permanent after death, never fails to leave a deep crimson line of redness round the burn, not removeable by pressure. Vesicles also are generally raised, which are found to be filled with serum.

Poisoning.—Poisoning has sometimes been enumerated among the acts of fatal injury practised with a view to infanticide. But there is, probably, not a single case on record to show that such a mode of murdering the new-born infant has ever been had recourse to. It is, however, by no means impossible that cases of poisoning may occur; and therefore the examination of the contents of the stomach, where there is room for suspicion, ought not to be neglected. Chemical analysis will, of course, be necessary for establishing the proofs; but an account of the particular processes to be adopted must be reserved for another part of the course.

Question of Omission.

There are two other modes of wilfully procuring the death of the new-born child, a notice of which ought not perhaps to be omitted, although they cannot be

immediately classed with the preceding forms of criminal violence, nor do they amount to infanticide, in the interpretation, or perhaps the spirit, of our laws. Most of the continental medical jurists divide infanticide into two kinds—as it is effected by commission or by omission. But infanticide by omission, implying that the infant has been wilfully lost through gross negligence, or by denying it certain necessary attentions, is not recognized as a crime by our penal statutes: we indict for murder, or concealment, or not at all.

Yet wilfully omitting to tie the umbilical cord, though not always fatal, deserves to be considered as a very criminal act, especially when taken in connexion with concealment. Much controversy has existed relative to the importance or non-importance of putting a ligature on the funis after it has been lacerated, or cut. But though it were demonstrated in ninety-nine cases out of a hundred that no mischief followed the omission, the fact of its proving fatal, even in a single instance, is sufficient to show the danger of omitting it. The infant may perish by hæmorrhage, the signs of which are obvious in the blanched and almost bloodless state of the body, both internal and external; a state which is more likely to occur after the cord has been severed in the usual way, than when torn by the hand.

Exposure.—Death procured by wilful exposure of the living infant, though not absolutely amounting to child-murder within the meaning of our law, must greatly aggravate the crime of concealment of the birth. The signs by which the medical jurist is guided in forming an opinion in such cases, must chiefly be gathered from the circumstances,—such as the time and place, together with the appearance of the body—destitute perhaps of covering, and (though the meconium be all expelled) having no alimentary matter in the stomach.

Having thus examined all the principal points connected with the second question involved in inquiries respecting infanticide, I shall conclude the whole subject by giving, as I did at the end of the first section, a brief *resumé* of the signs of natural and of violent death.

Signs of natural death.—We infer that there is no ground for the charge of infanticide, but that the child, though born alive, sank in the course of nature—

1. When there is a complete absence of marks of violence; or when those discovered may fairly be attributed to accident, or can be proved to have been occasioned after death.

2. When the child is malformed, weakly, or immature, and has apparently perished in consequence of a tedious labour.

3. When there are evident marks of disease, and of a character likely to have terminated fatally.

Signs of death by violence.—Some of these are so obvious as to need no particular description: but where the circumstances are such as to warrant at least suspicion in the first instance, we may be led to a more determinate view of the case—

1. When, with or without distortion of the features, or unnatural aspect of the body, the internal examination shows that some foreign substance was introduced, by means of which respiration was impeded.

2. When the signs of asphyxia, or smothering, are found in the chest, with traces of injury—pressure, with ecchymosis, for instance—about the throat.

3. When, together with the appearances of asphyxia, there is froth in the air-passages, and water, or some of the fluid in which the body was found, in the stomach.

4. And lastly, when the marks of wounds, or blows, or burns, are observed on such parts of the body as would not be likely to suffer from accidental injury; and when such wounds, blows, or burns, indicate, by the appearances of vital reaction, that the infant was not yet dead when they were inflicted.

CLINICAL LECTURES,

DELIVERED AT THE

MEATH HOSPITAL AND COUNTY
OF DUBLIN INFIRMARY,

During the Session 1836-7.

BY PROFESSOR GRAVES.

LECTURE VI.

Further remarks on the Treatment of Fever—

Management of Delirious patients—Advantages of Tartar Emetic in the form of Enema—Subsultus tendinum sometimes from disturbance of the nervous extremities, independently of the brain or spinal cord—Vomiting and purging at the commencement of Fever, indicative of cerebral affection—Scrofulous inflammation of the brain—Chronic scrofulous fever.

In speaking of the use of drinks in fever, I alluded to the abuse of soda or Seltzer water, and effervescing draughts. It is very much the custom, both in hospital and private practice, to look upon the latter as a remedy which may be administered at the pleasure of the patient, or the discretion of the nurse. They are cer-

tainly to many persons a most grateful means of cooling thirst; but the cautious physician will never allow his patient to indulge too much, for he knows that their frequent use distends the stomach, and produces a tendency to tympanitis and bowel complaint. I am also of opinion that the exhibition of large quantities of free carbonic acid is a very doubtful, if not a dangerous, practice in fever, and may increase that tendency to narcotism and functional derangement of the nervous and respiratory systems, which is observed in every case of genuine typhus. In addition to this, the evolution of a large quantity of fixed air in the stomach frequently causes a very disagreeable sense of distension and suffocation, and acts injuriously on the mucous membrane.

Allow me here to digress a moment from my subject, and make a few observations on a case which terminated fatally in our wards within the last twenty-four hours. I wish to call your attention to this case more particularly, as I think a different plan of treatment might have succeeded in saving the man's life. This man was admitted into the fever ward about the seventh or eighth day of his illness. I cannot exactly state how he was treated in the commencement, but I believe he was very badly attended, and that the state of the principal organs was wholly neglected. It will be sufficient to state, that when he came under our care the chief features of his case were delirium, accompanied by total want of sleep, and a violence of conduct and behaviour calling for the restraint of the strait waistcoat. Now under circumstances of this nature the most diligent attention and promptitude are imperatively demanded on the part of the physician, and every step calculated to anticipate danger should be instantly taken. I regret to say that I did not at the time take a correct view of the treatment, or precautions necessary to be adopted under such exigencies. I did not expect that the case would terminate fatally in such a short time, and I anticipated benefit from the remedy prescribed. He was ordered to take the tartar emetic solution in full doses; but on visiting him next morning, we found that he had obstinately refused to take his medicine, and that his symptoms were greatly aggravated.

In delirium of this kind it is certainly very difficult to manage the patient, and we are frequently obliged to have recourse to force or stratagem to make him take his medicines. I regret extremely that this man's head was not leeches on his admission, as, from the state of his pulse, I think he would have borne it well. Eight

leeches might have been applied to his temples, and repeated two or three times the same day, according to the state of his pulse and strength. I think I was wrong in contenting myself with ordering the tartar emetic solution and a blister to his head, and I should have anticipated from the violence of his behaviour that it would be very difficult to manage him.

In cases of this kind, where it is necessary to give tartar emetic (and this is one of the best remedies you can employ in cases of cerebral excitement in fever,) you should be always prepared to obviate any omission arising from the obstinacy of the patient; and when he will not take his medicine voluntarily, you may secure its effects on the system in two different ways. In the first place, it may be secretly mixed with the patient's ordinary drink; and as such persons are generally thirsty, and seldom refuse drink altogether, an intelligent nurse will readily find means to make the patient take a sufficient quantity of it to secure its full effect on the cerebral circulation.

Another expedient which you may resort to on similar emergencies, is to give the tartar emetic in the form of enema. I had recourse to this plan some time back, in a similar case of delirium, and with the best results. After leeching the head, I gave the solution of tartarized antimony in enema; and this can be always done, whether the patient likes it or not, if you take care to prevent his struggles by confining him in a strait waistcoat. The best way of administering it is to dissolve two or three grains of tartar emetic in four or five ounces of mucilage of starch or isinglass, and inject it with the aid of a long flexible tube, so as to make the contents of the syringe pass high up into the bowel. In this way you can secure all the good effects of tartarized antimony in overcoming the congestion of the brain, and procuring sleep. In all cases of alarming congestion of the head in fever, I have been long in the habit of using tartar emetic in this way, if the stomach be deranged, and incapable of bearing it safely; and I can assure you that it is a most fortunate thing to have such a powerful resource in all cases of the kind. I have also not unfrequently given expectorant medicines in the same way, where from the state of the stomach, or the debility of the patient, the ordinary remedies could not be administered by the mouth with sufficient rapidity, or in sufficient quantity to produce the desired effect. In this way I have often given the infusion of *ipecaeuana*—a remedy of very considerable value, and not sufficiently appreciated by most modern practitioners. I may also remind you that vomiting, and all the

benefits derivable from it, may be likewise produced in this way. Now where the stomach is irritable, and yet there exists a necessity for such remedies, it is a very fortunate circumstance to be in possession of a means of employing them without inflicting any injury on the stomach, and thus counterbalancing the good effects of the remedy by the injury done to the stomach. Of course the cases in which these expedients are required are comparatively rare, but the practical physician must be always prepared for such exigencies, and be provided with every means of meeting them.

Another of our patients died also within the last few days in the fever ward. He laboured under a very bad form of maculated fever, and when admitted, was evidently in a hopeless state. I shall not say any thing about this case, except to use it as an occasion for making a few observations on a particular state of the cerebro-spinal system, which we not unfrequently observe in cases of maculated typhus, and occasionally in other varieties of fever. Now you observed that this man had not the slightest tendency to sleep; that he lay with his eyes constantly open, raved incessantly, had subsultus tendinum, floccitatio, and cold extremities, and often attempted to get out of bed. Yet we could not find in him any thing like decided evidence of cerebral inflammation. The tunica adnata was of a clear pearl-white, the face pale, and the scalp and integuments of the face cool. You perceive, then, that sleeplessness, delirium, and subsultus tendinum, may depend on a state of the nervous system having no connexion with congestion of the brain, or determination of blood to the head. This occurrence has struck me very forcibly in many cases of fever. But I have been most particularly struck with the occurrence of subsultus tendinum in such instances. In the present case we had a patient with sleeplessness and subsultus. But this concurrence of symptoms does not always exist. You recollect the case of the boy in the small fever ward, who laboured under excessive subsultus, and to whom we gave the spirit of turpentine in drachm doses with so much benefit. Yet this boy, as you all remember, slept remarkably well. I have frequently pointed out to the class patients labouring under subsultus tendinum, who slept well, and in whom the tunica adnata was of a pearl-white colour, without the slightest suffusion. We have subsultus, therefore, occurring in two very opposite states of the nervous system; we have it accompanied with loss of sleep, and we have it existing in that condition of the system where the patient slumbers long and heavily, and cannot be easily

roused. Hence I am inclined to think that the cause of subsultus resides not so much in the nervous centres as in their extremities. I would even go so far as to advance the proposition, that if it were possible for the fever to go on, and life to continue after the removal of the brain and spinal cord, I am quite sure that the subsultus would continue. I am almost confident that subsultus tendinum is the result of some derangement of the nervous extremities. I have shown on a former occasion, when lecturing on the subject of paralysis, that the nervous periphery may become diseased primarily, and without any antecedent affection of the brain or spinal cord. I think it extremely probable that in fever the nervous centres are subject to certain derangements producing coma, sleeplessness, and delirium, but that there are other nervous symptoms which are to be referred rather to a derangement of the nervous extremities, and among the latter I would particularly include subsultus tendinum, a symptom which we find co-existing with such opposite conditions of the nervous centres.

But to return to the case to which I first alluded. Never blister in the early stage of fever, until you have applied leeches in sufficient quantity. In this case, it is true, we could not well ascertain what the period of the fever was; for the man was brought in in a state of delirium, and there was nothing known respecting his previous history. Yet you are all aware that a great deal must depend on our knowledge of the period of the fever, and the medicines which have been employed. Had we been acquainted with these circumstances, it is probable we would not have fallen into the error we committed. What I wish to impress on you, is, that in all cases of maculated typhus, you should be careful in examining the head and ascertaining whether there are any evidences of cerebral congestion present. If there is headache, strong pulsation of the carotids, suffusion of the eyes, and heat of the face and scalp, along with the other signs of functional lesion of the brain present, you should always have recourse to leeching; beginning cautiously, and continuing their application as long as the patient will bear it with safety. When you have the symptoms already mentioned, and the patient is in the early stage of fever, you may commence by applying one or two leeches to the nostrils, or six or eight to the temples, or behind the ears, repeating them two or three times a day, according to the exigency of the case. The best way of using leeches is to apply them in small numbers every six or eight hours, so as to keep up a constant drain from the head. After you have

leeches sufficiently, you may then have recourse to blisters. In making this change, much will depend on the sagacity and skill of the practitioner; for it requires no ordinary tact to hit on the proper time when you should give up leeching and commence with blisters.

I shall make no apology for introducing here what I consider to be an important observation, with reference to the pathology and treatment of fever. We had a striking instance of the fact on which I am about to offer some comments, in the case of a little girl who died lately here, in a very remarkable manner. I mentioned in a former lecture, that vomiting and purging in the commencement of fever are, generally speaking, indicative of a cerebral affection. Every fever which commences with vomiting and diarrhoea, whether it be scarlatina, or measles, or typhus, is a fever of a threatening aspect; and in all such fevers the practitioner should be constantly on the watch, and pay the most unremitting attention to the state of the brain. There is much difference between the vomiting and diarrhoea of gastro-enteritis and this cerebral diarrhoea and vomiting. The latter sets in generally at a very early period of the disease, perhaps on the first or second day, and is seldom accompanied by the red and furred tongue, the bitter taste of the mouth, the burning thirst, and the epigastric tenderness, which belong to gastro-enteric inflammation. There is also another source of diagnosis, but of a less valuable kind; and this is founded on the results of treatment. Gastro-enteric vomiting and diarrhoea are relieved by leeching the belly; but I need not tell you that this mode of treatment can have no effect on the vomiting and purging produced by cerebral disease. There is also another source of diagnosis: the vomiting and diarrhoea which results from gastro-enteric inflammation is never accompanied by such copious discharges of bile as that which depends on disease of the brain. In diarrhoea from derangement of the brain, the quantity of bile passed is very remarkable; and it is equally curious, that when vomiting follows derangement of the cerebral circulation, in ordinary cases, and without fever, bile is thrown up in very large quantities. This is frequently observed in persons who become sick from swinging, or sailing. In such instances, a larger quantity of bile is vomited than could occur from mere gastric irritation. Now in the commencement of cerebral disease, where congestion or inflammation is present, one of the first symptoms is copious vomiting, and purging of a bilious character. This is very often the case in scarlatina, and there are few cases in which there is more

danger to be apprehended. We had these symptoms, under very unfavourable circumstances, in the little girl to whom I have just alluded. From the imperfect history of the case which we were able to obtain, it appeared that she had been ill of fever for fourteen days before her admission, and had in addition a severe attack of bronchitis and pneumonia. She then got inflammation of the stomach, and finally congestion of the brain, as indicated by the cerebral vomiting and purging. We employed every means in our power to check these symptoms, but without success; she went on from bad to worse, and she ultimately sank under a combination of affections, which you will frequently observe in many forms of disease as well as in fever; and it is to this point in particular that I wish to direct your attention. You will frequently observe that a certain period of fever, whether it be inflammatory, nervous, bilious, or typhoid,—and very often in other forms of disease, whether depending on a general affection of the system, or connected with inflammation of important organs, when the patient has been going on pretty well for some time,—you will find that about the period when you would naturally expect that the fever would go off, and convalescence begin, a new form of fever makes its appearance, and carries off the patient in spite of all your exertions. To this form of secondary fever I would give the name of *scrofulous*, because it resembles in its chief features the intractable form of fever which is frequently observed in persons of an originally *scrofulous* habit, or who have become so from the abuse of mercury or other debilitating causes. This is a form of fever which is not well understood, and I am not acquainted with any author who has devoted to it that share of attention to which, from its great importance, it has such decided claims. Its chief characters are, that the patient, during its existence, exhibits a strong tendency to inflammatory affections, which bear a close analogy to the *scrofulous*, both in their intractable character, in the facility with which they pass from one organ to another, and in their frequently unfavourable termination. A patient of this description, while labouring under fever, will frequently exhibit a very remarkable succession of inflammatory affections. If, during the course of his fever, he gets an attack of gastro-enteritis, you will have great difficulty in managing it; and no sooner is this overcome, than he is seized with bronchitis or pneumonia; and when, by great care and the most skilful treatment, you have overcome this also, he gets *scrofulous* inflammation of the brain, and dies. Now you will fre-

quently meet with patients who, during the course of typhus, will be attacked with this bad form of fever, and get what may be termed *scrofulous* inflammation of the brain, which carries them off in five or six days, in spite of all your care. You are aware that persons who are much in the habit of observing diseases of the brain, can generally distinguish between *scrofulous* inflammation of the brain and its membranes and that inflammation which occurs in persons of healthy habit. In cases of the latter description, the treatment, if commenced at the first appearance of the disease, is simple and successful. Appropriate bleeding and leeching, with the use of calomel and James's powder, are almost always sufficient to accomplish a cure. When once you have succeeded in touching the gums with mercury, the patient's safety is tolerably certain, and recovery is in general rapid; but in the *scrofulous* affection of the brain, although you may have fully mercurialized your patient, you will too often discover that you have merely retarded the progress of the complaint for a brief period; it returns again, and carries him off in spite of all your efforts. In the *scrofulous* hydrocephalus, a much greater time elapses from the appearance of coma and strabismus until death takes place, than in the ordinary forms of meningitis. This fact was well illustrated in the case of the little girl to which I have just now referred: she continued to live on for a long time after the appearance of symptoms which you would think ought to terminate fatally in a few hours after they had become developed. There is also a great deal of irregularity in the way the symptoms come on in cases of *scrofulous* inflammation of the brain. Sometimes blindness is one of the first symptoms. I recollect having been called, with Dr. Beatty, to see a very fine boy, living in Merrion-Square, and was very much struck, on entering the drawing-room, to find him walking about, and in apparent good health, but quite blind. Here amaurosis was the first symptom. This was subsequently succeeded by others, and he died in a convulsive fit about a fortnight afterwards.

We have many excellent observations on the chronic *scrofulous* fever, but I think that there is no author who has described this acute form with the precision and care which it deserves. It is, however, a very frequent form of fever, and you will see many examples of it among the chronic patients in the medical and surgical wards. You will frequently observe persons who are labouring under acute disease from accidents or other causes, become feverish and ill again at a time when

you expected a remission of their symptoms, or even recovery; and, without any assignable cause, they will get serofulous inflammation of some other part or organ, and quickly fall into a state of hopeless and incurable disease.

REMARKS

ON THE

NATURE AND TREATMENT OF RHEUMATISM*.

By J. HOPE, M.D., F.R.S.

IN speaking formerly, gentlemen, of the "varieties of inflammation according to tissues," I said that acute rheumatism presented the most striking exemplification of inflammation of the fibrous tissue, viz. tendon, ligament, fascia, aponeurosis, the dura mater, and pericardium (of which the external layers are fibrous), the valves of the heart (which contain fibrous tissue between the reduplication of the lining membrane), periosteum, neurilema, and the sclerotic coat, and cornea of the eye.

I told you that any one of these parts might be inflamed individually, and that then the disease was not called rheumatism, but inflammation of the part. But if there be a general tendency throughout the whole system to inflammation of the fibrous tissues, the disease is then denominated rheumatism.

Forms.—Rheumatism, like other inflammations, is, 1. *Acute*; 2. *Chronic*: and the chronic presents two varieties, *a. Active*, i.e. increased local action and heat, mostly with, but sometimes without, constitutional fever; *b. Passive*, i.e. diminished local action, with coldness, and without fever. I shall consider each of these forms in succession.

I. ACUTE RHEUMATISM, vulgarly called rheumatic fever.—Under this head I do not comprise rheumatism of the periosteum, the neurilema, and the eye—of which, hereafter; but I allude to rheumatism of tendon, ligament, fascia, aponeurosis, dura mater, and the pericardium and valves of the heart.

Local symptoms.—The parts usually attacked are the three great joints of each extremity; more rarely the small joints. There is heat, pain of an obtuse yet severe kind, and, in most, but not all, there is redness and swelling: in short, there are the four local signs of inflammation. The

pain is aggravated when the patient is heated in bed, especially at night; also by pressure and motion; whence, and from the swelling, there is more or less rigidity of the joint.

Constitutional symptoms.—The constitutional symptoms are peculiar and very remarkable. The pyrexia, in severe cases, is far more violent than corresponds with the degree of local inflammation, and also of danger, provided no internal organ be affected.

The pulse is from 90 to 110 or 120, full and bounding—not hard—not tense, and incompressible, as you see it in inflammation of serous membranes and inflammatory fever; but compressible, and bounding like the pulse of a healthy person accelerated by running; and by this bound and its speed, it indicates great arterial action. The respiration is accelerated in proportion to the rate of the pulse. The tongue is singularly white, and has a pasty surface, yet without being thickly furred. Bowels confined; urine scanty and high coloured, early depositing a copious lateritious sediment. Skin hot—hotter, indeed, than in most other inflammations; but what is very remarkable, and I believe unique, it usually perspires freely—often profusely; and, in a day or two, the perspiration becomes offensively sour, so that some say they can diagnose acute rheumatism by the nose.

These perspirations I regard as an essential part and peculiarity of the disease; for they commence simultaneously with it, and, instead of relieving, they only exhaust the patient. The tolerance of blood-letting is great; that is, the patient bears much loss of blood without fainting. Finally, the blood is, in general, buffed and cupped in an extraordinary degree; and I have often seen this continue, though the patient was bled to the last ounce that could safely be drawn.

Causes of the swelling.—The swelling is occasioned by vascular turgescence, and by serous effusion into the fibrous and cellular tissue—that is, oedema; and with this you will sometimes find a little synovial effusion into any contiguous synovial membranes—namely, of sheaths of tendons, bursæ, and joints. This you would naturally expect, as the inflammation is propagated from the fibrous tissue to the synovial membranes by contiguity of tissue, according to the well-known principle of Bichat. The swelling from these causes is inconsiderable. This is the kind of swelling in the great majority; my impression would lead me to say in 19-20ths. In the remaining 1-20th there is little or no serous effusion into the fibrous and cellular tissue, but a very copious synovial effusion. This fact was, I believe, first

* Being an abstract of a lecture delivered recently at the Aldersgate School of Medicine.

noticed and taught, in his lectures, and in the wards of St. George's Hospital, by Dr. Chambers; and he made it the ground of a practical distinction into "*fibrous*" and "*synovial*" rheumatism.

In "*fibrous*," the swelling is diffuse, pits on pressure, and is inconsiderable in degree; and this variety alone is attended with the violent constitutional fever, such as I have described it.

In "*synovial*," the swelling takes the form of the particular synovial membrane affected: it is elastic and fluctuates, and may enlarge the joint even to double or triple its natural size. Dr. Chambers remarked that the fever was not of the violent kind which attends fibrous rheumatism, but a much milder degree. I have noticed, that though the fever is occasionally smart at the onset, it subsides as soon as the effusion becomes considerable,—that is, within three or four days; a circumstance attributable, I presume, to the effusion relieving the inflammation, which is nature's own mode of affording relief. After the effusion has taken place, the complaint assumes a more chronic form, with little symptomatic fever; is removed more slowly than fibrous rheumatism, and is more benefited by local treatment: in short, it becomes more strictly a local complaint—more a mere effusion into the joint. The knee is, beyond comparison, the most frequent seat of synovial rheumatism, but any other joint may be affected; and the small joints are, according to my observation, more obnoxious to this than to the fibrous variety. The lower classes, indeed, know it practically under the name of rheumatic gout, though there be no gout in the case.

Rheumatism rarely suppurates.—A peculiarity of rheumatic inflammation is, that it scarcely ever ends in suppuration—some say, never; and that when suppuration does occur, it arises from some other inflammation, either accidentally present or excited by the rheumatism. Thus Bouillaud relates two cases of what he considers to be acute rheumatism, terminating in suppuration; but in both, phlebitis attended the rheumatism, and was pretty evidently the cause of the purulent effusion amongst the muscles and tendons. Dr. Macleod also mentions two cases of purulent effusion into the synovial membranes (*MED. GAZ.* vol. xvii. p. 656); but, in both, the disease had become "persistent" in the joints affected—the hip and shoulder in one, and the hip in the other. Here, then, the rheumatism may have degenerated into mere chronic inflammation, which, of course, may suppurate. The strength of the whole argument turns principally on this point—that if rheumatic, did not differ from common inflammation, we ought

to find suppuration in the acute stage. Of this, however, I have never myself met with an instance, though I have seen no small number of cases; nor have I been able to find a case on record which did not seem to admit of a double explanation. On the whole, therefore, I think we may conclude that rheumatism has the peculiarity of not tending to suppuration; and that when it occurs, it is an exception to the general rule. Mortification is still rarer than suppuration.

Migration of acute rheumatism.—Migration is another striking peculiarity of acute rheumatism. In general, two, three, or more joints, are primarily affected: then it leaves some of these, and attacks others, or other parts; and occasionally it revisits the joints originally affected. The joint which it leaves is promptly eased of pain, but not necessarily so of the swelling; for if the œdema is considerable, a day or two may be necessary for its absorption.

By far the most important of its migrations is to the fibrous tissue of the pericardium and valves of the heart. That to the dura mater is comparatively less important, because very rare: I have never seen an instance: whereas migration to the heart is exceedingly common. It occurs in perhaps one-half, if not counteracted by suitable treatment. Thus M. Bouillaud rates it at half, including the cases of inflammation of the valves, which he says with truth is almost invariably overlooked by non-auscultators.

If, then, you consider that, independent of the *immediate* danger of pericarditis and endocarditis, an adhesion of the pericardium, or a disease of a valve, so frequently entailed by these diseases, necessarily cripples a man for life, and often contracts his existence within the span of a few years, you at once see that acute rheumatism, formerly considered harmless to life, is really a disease of the first magnitude and importance, and always to be regarded with anxiety.

Metastasis.—The migration of rheumatism to the heart or head used to be called and considered "*metastasis*,"—that is, a change of seat,—a total desertion of the external parts, and a concentration of the disease on the internal organ. But this idea is erroneous, and, I trust, becoming obsolete; for I have often seen the heart attacked while the disease was in its full intensity in the limbs,—nay, I have even seen the heart attacked first! The disease, therefore, merely extends or migrates to the internal fibrous tissue, just as it does from joint to joint, by what Bichat calls the affinity of tissue.

Rheumatism a specific inflammation.—Rheumatism has long been considered a "*spe-*

cific" inflammation,—by which I mean, one not presenting the usual phenomena, nor running the usual course of common inflammation. John Hunter was of this opinion. It has of late, however, been questioned with ability; yet I confess I adhere to the old opinion, and on the following grounds:—

1. The migration to all parts of the fibrous tissue is unique. You see it not in inflammation of any other tissue, nor even in common inflammation of the fibrous tissue.

2. The very slight tendency to suppuration, ulceration, and adhesion, is peculiar; for all these processes are common in ordinary inflammation of fibrous tissues, as from injuries, &c.

3. The perspirations are unique; even the whiteness of the tongue is singular.

4. The excessive buffing and cupping of the blood, sometimes even after the utmost possible venesection, is extraordinary, and seems to indicate something peculiar in the constitution of the blood.

5. Experience shows that this disease is less certainly and uniformly relieved by antiphlogistic treatment than other inflammations.

All these circumstances evince, I think, something peculiar—"specific"—in the system, or, if you please, in the vital constitution of the blood, which, I believe, is M. Andral's opinion.

I have dwelt a little on this subject, not from the love of idle speculation, but because, if the inflammation be specific, we are not rigidly bound in the treatment by the ordinary principles of inflammation, if we find them less than usually successful; but are justified in circumspect deviations, approved by experience.

II. CHRONIC RHEUMATISM.—This, I said, may be "active" or "passive."

The symptoms of active chronic rheumatism are much the same in quality as those of acute, but less in degree. Though the disease has lasted many months, you may still find the parts, from time to time, more or less painful, hot, swollen, and even red, and the pain aggravated by heat. There may also be a moderate degree of symptomatic fever, the pulse ranging from 80 to 90. Sometimes, however, there is no symptomatic fever, the activity being strictly local. You will seldom find perspirations, as they cease after the few first weeks.

This chronic form may either be the sequel of the acute, or be primitively chronic; and I have often noticed repeated chronic recurrences in those who had once had acute.

Age.—I have not found acute rheumatism very frequent before æt. 6, and after 60.

The most common period of its prevalence is from æt. 8 to 35, during which it is, beyond comparison, the most frequent cause of peri- and endo-carditis. I have ascertained this almost numerically in a great number of cases.

MODES OF TREATMENT.—The treatment of acute rheumatism has been—nay, is—very unsettled. There is the bleeding and purging plan; the forced sweating plan; the stimulant plan—that is, with bark, guaiacum, &c.; the colchicum plan; the calomel and opium plan; and these variously combined. The importance of this disease, especially with reference to inflammation of the heart, has led me to pay much attention to its treatment for the last eight or ten years; and I have made brief notes of between two and three hundred cases, and observed many more. My object was to curtail, if possible, the exhausting six weeks' treatment of the old school, and to ascertain what mode would best obviate that truly formidable complication, inflammation of the heart. As my opinion is now pretty decidedly formed, I shall offer you the results of my experience.

1. *The bleeding and purging, or pure antiphlogistic plan.*—From ten to twenty years ago, this and the diaphoretic plan were in full vogue, especially in Scotland; and I saw them carried to their maximum in the Edinburgh Infirmary, during a residence of two years in that institution. Now many cases, I admit, were promptly and effectually cured—even annihilated at once, by the antiphlogistic plan; but, in many others, active bleeding was carried to the very last ounce that could be drawn; yet the enemy clung to the joints with a chronic grasp, and proceeded triumphant in his crippling career. Add the pale emaciated frame, and the slow convalescence, sometimes of two or three months' duration, and too often, I fear, the permanently shattered constitution; add, above all, inflammation of the heart not prevented: nay, it is a trite remark, and by none made more strongly than by Dr. Alison, "that large and repeated bleedings in the beginning of rheumatism, he is convinced, *increase* the risk of this metastasis.*" Dr. Macleod has, however, ingeniously and fairly met this argument, by saying, that it is only in the worst cases, and consequently those in which migration to the heart is most *likely* to occur, that copious bleeding has been employed. Still the fact remains, that inflammation of the heart is not *prevented*, and prevention is the great desideratum.

The forced sweating plan.—Dr. Gregory,

* Cyclopædia of Medicine: Hist. of Med., Part xxiv., page 45.

the great advocate of this plan, premised venesection and purging till the pulse was lowered to 100; but "with these appliances and means to boot," I have seen patients stewed and parboiled (if you will excuse a culinary trope) for four, six, or eight weeks, and gain—what?—a wan attenuated frame, chronic pains, and a confirmed susceptibility of rheumatic attacks on the slightest variations of temperature. This plan is now, I think, almost universally abandoned,—by those at least who keep pace with modern science.

The stimulant plan.—It was principally Morton, Fothergill, and Haygarth, who gave bark from the first, or nearly so; and I have seen others give guaiacum (a stimulant and diaphoretic) in the same way. I have not myself tried these remedies, because I never think myself justified in employing remedies distinctly opposed to reason when I know of others equally efficacious which are consistent with reason; but I have looked on the treatment of others; and it has always appeared to me that the patient has recovered in spite of the remedy, and in virtue of the bleeding, purging, calomel, or low diet, which was simultaneously employed, and to which in some cases the practitioner was compelled to resort at an advanced period of the treatment. Bark, however, is good in a weakly convalescence, just as after any other inflammation.

The colchicum plan.—Colchicum is a powerful remedy, and, with antiphlogistic treatment, often succeeds well. Those who are most partial to it generally consider that its most striking effects are produced when it purges; and to promote this they often conjoin with each dose magnes. carb. ℥j. or some other neutral salt. It is apt, however, in full doses of 3ss. to 3j. or ij. to produce an intractable dysenteric diarrhoea, which upsets all your plans. I have so often been foiled by this circumstance, that I now use colchicum only as an auxiliary, in small doses of ℥xv. to xx. frequently repeated. In this way I use it much.

Calomel and opium plan.—This was introduced for acute inflammation in general, and for acute rheumatism in particular, by Dr. Hamilton of Lyme Regis, fifty years ago*. He bled once or twice, and touched the salivary glands with mercury, with brilliant success. But there is an objection to unnecessary salivation. A modification of this plan, by which ptyalism is avoided, I first saw employed by Dr. Chambers, at St. George's Hospital. It is to this plan that I wish

particularly to call your attention; and, leaving the merit to him, I shall give you my own experience of it during the last six years, in about 200 cases of acute or active chronic rheumatism.

1. *Acute.*—After a full venesection, or even two, in the robust, but without bleeding in the feeble and delicate, I give every night gr. vij. to x. of calomel with jss. to ij. of opium, according to the age, and the severity of the case; and every morning a full haust. sennæ, to act four or five times at least. In addition I generally give the following draught, thrice a day, as it has appeared to me to expedite the cure—partly, perhaps, by the additional opiate, and partly by the sedative effect of the colchicum.

Rx Vini colch. ℥xv. ad xx.; Pulv. Doveri, gr. v.; M. salin. 3x.; Syrupi, 3j. M.

When the pain and swelling are greatly abated, if not almost gone, (which often happens within two days, and almost always within four,) I omit the calomel; or if the gums become in the slightest degree tender, I omit it even earlier. The opium I continue to the extent of gr. j. or jss. at bed-time; and in severe cases I add a grain at noon; for without an anodyne the pains are apt to recur. I also continue the colchicum draught and the haust. sennæ, as before.

No local treatment is necessary beyond warm or cold application, according as the patient finds them agreeable.

If the patient is not well in a week I consider it a case of exception; and the exceptions are generally in those who are subject to rheumatism, and who therefore usually have it in a more obstinate chronic form.

The advantages of this plan are, 1, that a patient is generally sound, well, and fit for work in a week or ten days after the pains have ceased; 2, that the gums are rarely affected, especially if you previously ascertain that the patient has not a morbid susceptibility of mercury; 3, that it is rare to see inflammation of the heart if the treatment is early begun (I think that one case in a dozen would be the maximum in my practice); 4, if the slightest symptom of endo- or peri-carditis does supervene, a few extra doses of calomel and opium, as gr. v. c. op. gr. j. every four or six hours, will generally affect the constitution in twenty or thirty hours, which, with two or three cuppings or leechings on the region of the heart, almost always places the patient in a state of safety. I have never lost a patient by rheumatic pericarditis since I employed this plan; and I have been told by other hospital practitioners that they

* In 1763. See Med. Commentaries.

have been equally successful by the use of calomel and opium.

2. *Chronic active.*—Here calomel and opium may be given in smaller doses, as calomel, gr. v. and opium, gr. j. every night; but they require to be continued for a longer time, as five or six nights. Take care, however, to stop short of ptyalism, especially in the scrofulous. Local treatment, too, is more beneficial than in the acute form: viz. bleed locally rather than generally, and ultimately employ blisters, liniments, &c.

Trials of modifications.—I have tested this plan by successively omitting the venesection, the purging, the calomel, and the opium; and with each omission I have found the recovery less expeditious and certain. I cannot doubt that the opium contributes importantly to the cure,—perhaps by allaying the pain, and thus diminishing the irritative fever dependent on it; or, possibly, by modifying the vital state of the blood: but this is yet hypothetical. I have, however, assured myself of the fact, that opiates and purging alone will cure many cases of acute rheumatism remarkably well. Others, too, have used narcotics with success. I think Dr. Hue, of St. Bartholomew's Hospital, treats acute rheumatism with large doses of conium, as ℥j. or more daily; and my friend Dr. Lombard, physician to the hospital of Geneva, states that he has had remarkable success with the spirituous extract of aconite, in doses of gr. ss. gradually increased to two or even three grains, every two hours.

Treatment of synovial rheumatism.—Calomel and opium produce less striking effects on purely synovial rheumatism, because the inflammation soon relieves itself by the effusion, and the effusion requires time for its absorption. Yet I am satisfied that mercury does expedite absorption in this as in any other effusion. Colchicum, however, has the reputation of producing its best effects in synovial rheumatism. I have oft looked for "heroic" effects, in vain; and I suspect that they are rather over-rated: yet it is a good remedy. Whether you use calomel and opium, or colchicum, or both, for synovial rheumatism, you will find that local applications are more necessary and serviceable than in fibrous rheumatism, viz. leeches, c. cruenta, cold lotions, hot fomentations, and poultices; and later, blisters, stimulant liniments, and plasters, &c. Leeches and blisters should never be placed immediately upon a superficial joint—I have seen them create ulcers which penetrated the joint and proved fatal. * *

CHARACTER OF THE PREVAILING INFLUENZA.

To the Editor of the Medical Gazette.

SIR,

HAVING perused in your valuable journal of the 4th inst. the letter of Mr. Henry Bullock, on the Nature and Treatment of Influenza, wherein he ascribes the former to specific contagion, permit me, through the same medium, to dissent from him, basing my objection on the immediate percursory atmospheric change. I am aware at the same time that there are very high, though not undeniable authorities against me, viz. Cullen, who designates it in his *Nosology and First Lines, Catarrhus contagiosus*; and Dr. Gregory, in following him, admits there are many opponents to such an opinion.

Here, at the latter end of December and beginning of January the cold was extreme—considerable quantity of snow fell in a comparative short time; this was succeeded by a hard and severe frost, then again as sudden had we a rapid thaw, followed by strong westerly gales, and much rain. Quick upon this change the list of my dispensary patients increased during the last week of December to 13 more than ordinarily, 45 in the whole of January, and 40 in this fortnight of February, all of which were catarrhal cases. I could not help noticing at that time the prevalence of a similar epidemic among the quadrupeds in general.

One may at first be inclined to ascribe so universally indiscriminating an effect to contagion, but is not the rapid and extensive atmospheric mutation preceding the disease most apparently the true origin. Have we not in that change the cause? and can we find any contending difficulty against designating this sequent epidemic as the effect?

Since it is admitted that a partial sudden atmospheric change produces benign catarrh, it is but reasonable we should conclude that a more powerful, more sudden, and more illimitable vicissitude, conjoined with concomitant humidity of the weather, will be an efficient cause for the origination of our present prevailing epidemic, without searching for the additional aid of specific contagion. Perhaps Mr. B. can explain

ch manner this contagion propagate—whether by visitorial intercourse—posure to the local sphere of the amoisson—or by the universal extension—undefined, subtle, atomic particles contagious something floating

air. If the latter, we are far likely to have influenza raging the æstival than the brumal period of the year; in the former season consists could avail themselves of collateral acquisition in support of their peculiar opinion. Were we to

by analogy respecting the contagiousness of this disease, we might naturally expected to receive the disease by respiring the morbid atmosphere, by actual contact or cuticular infection, as in rubeola, scarlatina, typhus, and others.

ending this analogy a little further we might reasonably anticipate the secretion of the mucous membrane of the nose possessing the capacity of inosculating, of superinducing a disease, as the endermic absorption of a like morbid mucous secretion produces glanders in horses; and as canine saliva the hydrophobia. These facts establish an axiom, that morbid diseases exciting morbid actions are capable of generating epidemics; but this epidemic has not the power.

attributing catarrhus communis to cold change of weather, yet denying it catarrhus epidemicus, seems to me to be a warped judgment. Does every person know that he risks a severe cold by rushing from a calid atmosphere of about 90°, in crowded streets and overheated rooms, to a frigid one of about 40°, in the external

air, if each individual is liable to it from so partial a cause, is it not in accordant with common observation to find, in the populace at large, the varied symptoms of a similar disease when the cause of it only varies in its universality?

As to the treatment. Both Cullen and Gregory describe the influenza as an inflammatory disease, that being agreed by them the characteristic primary difference between it and catarrhus benignus: hence, as Mr. Armstrong adopts their nosological views, we might have been led to expect his treatment in accordance. On the contrary he finds bleeding (which they re-

commend) decidedly injurious, and protractive of recovery, by exhausting the constitutional powers. I have much pleasure in bearing testimony to the justice of Mr. B.'s denunciation of the full depletory plan in London; but here in the country, even when the symptoms only simulate inflammatory action, one general bleeding, or repeated if requisite, is had recourse to; and when the local pain in the forehead or temples is acute, or a feeling of heaviness and giddiness in the head, the topical application of leeches has been attended with the happiest effect.

Why there should be such a disparity in treating the same disease in town and country, may be very easily explained, by considering that the stamina of the constitutional powers of the metropolitans are not so vigorous as those in the country. This is one, and, I think, a cogent reason, why Dr. Armstrong changed the opinions he promulgated in his works on Fevers soon after he practised in London; for it is generally known that he recanted his published theory, and altered his practice. The adoption of his views proved very uniformly successful with me, where one of the largest country practices offered me the ample means of putting Dr. Armstrong's practice to the test of experience; and no doubt Mr. B. will feel the truth of my assertion, on learning it was the seat of his first pupilage. I have also had considerable experience, during two years of hospital study in London, around Mr. B.'s immediate neighbourhood, among the lowest of the low—poorest of the poor—a genuine colony of gin-tippers.

Impressed with a firm conviction of the excellence of Dr. Armstrong's practice, I carried it into operation among those individuals; but I quickly found my error, for the result of my treatment was the distressing collapse and protracted recovery of those in whose cases bleeding was fully resorted to, though the extent of such depletions was not carried so far there as I had priorly done in the country, with decided benefit, in similar acute inflammatory diseases. I also discovered that my town patients could not endure the powerful effects of my country doses of purgatives, were salivated quicker, and by lesser doses than I had been in the habit of prescribing. Surprised at this, I mentioned it to my friend Mr. Clarke,

the then surgeon for the parish of St. Olave, and now for the Union; he explained, and to convince me the more, he, in the next cases, commenced a milder plan, viz. less depletion, and when repetition was required, careful not to abstract indiscriminately: the medicinal auxiliaries were the same, but diminished in the dose. These instances, thus treated under Mr. Clarke's surveillance, to my infinite surprise and pleasure, rapidly recovered without a decimal portion of comparative debility.

I have intruded these observations to corroborate the aptitude of Mr. B.'s treatment for citizens, and to mark more widely their inaptitude for country adoption. I felt this the more necessary since your extensive publication may induce junior country practitioners to follow those measures which I hesitate not to declare they will find full of disappointment. The present epidemic has raged in this country very universally, and with unusual severe symptoms of the inflammatory kind; inso-much that private practitioners have been dubious whether to class it as the catarrhal epidemic, or purely as one of its own kind—a general inflammatory one; for three-fourths of the cases attacked with all the usual precursory symptoms of catarrh, set in pneumonitis, pleuritis, bronchitis, and rheumatismus acutus. I would also observe, that in all the townships to the extent of 12 miles around Manchester, I have ascertained that the mortality is, and has been, very great. The majority have died from uncontrolled inflammations; some of apoplexy. Several old people, chronically affected with bronchitis and asthma, have had these diseases so aggravated by the prevailing epidemic, as ultimately led to their deaths. I have several cases of idiopathic and symptomatic epilepsy, much aggravated both in frequency and severity of the fits.

To specify the symptoms of influenza as I have found it here, would be only reiterating what has been better expressed by yourself; suffice it to state that they have been with variations of the inflammatory kind, for which my treatment has been in accordance. When they have come to me, suffering under the oppressive stage, with much congestion in either organ, I have bled as freely as the urgency of the symptoms demanded, guided by the relief it afforded to the patient's feelings, and

produced on the action of the heart; and did my attendance happen to be required when the second stage had supervened, then again I bled to diminish the high and general excitement: of course the stomach and bowels were also promptly attended to, succeeded by the use of antimonial and saline adjuvants. Such has been my practice, and I flatter myself with its uniform success, not having had one death in near one hundred patients.

Should this letter be deemed worthy of space in your valuable periodical, its insertion will oblige

Your humble servant,

W. W. MORGAN.

Bury Dispensary, Feb. 16, 1837.

ABSCESS OF THE LIVER.

To the Editor of the Medical Gazette.

SIR,

It has been suggested to me since I had the honour of transmitting to the MEDICAL GAZETTE of the 4th inst. the brief account of a post-mortem examination of a woman who died of an extensive encysted abscess of the liver, that no notice was taken in the report of the state of the gall ducts; and as the same observation may probably have occurred to other of your readers, perhaps I may be allowed to state a fact which had previously escaped my memory.

Upon first viewing the extensive destruction which the liver had sustained, it was a matter of surprise that no decided symptom had manifested itself during life upon which to ground a probable diagnosis, but it appeared on a more minute investigation that the ducts, viz. the ductus hepaticus, the ductus choledochus communis, and the ductus cysticus, although surrounded on all sides by disease, were pervious and perfectly free for the transmission of bile into the duodenum. This circumstance, coupled with the fact of the comparatively healthy state of the digestive canal, accounts for the absence of jaundice and discoloured skin, (from both of which the patient was free.) one or other of which has been described by some authors as the invariable concomitant of hepatitis.

I am, sir,

Your most obedient servant,

R. H. ALLNATT.

Wallington, Feb. 15th, 1837.

INFLUENZA

AT THE

ST. MARYLEBONE INFIRMARY.

To the Editor of the Medical Gazette.

SIR,

IN reading your last number, I have observed one or two inaccuracies in my "Notice of the Influenza," which I should be glad to be allowed to rectify. In giving the total of deaths in the wards in the six weeks ending Feb. 10 last, I have included about 20 not belonging to the admissions of that period, but to those of the last year, without having sufficiently distinctly stated the circumstance, although important in its relations to the question of mortality. In the table of ages also the same inaccuracy occurs from, I believe, the same cause, viz.—haste. You will oblige me by giving early insertion to the accompanying more correct statement. Perhaps I may mention before concluding, that the total of cases of influenza occurring during six weeks in all the departments of the practice of the infirmary, which I estimate in round numbers at between 900 and 1000, does not, from want of data, include any attacks occur-

ring in persons resident, whether as officers, servants, or patients in the infirmary, at the beginning of that period, although such instances were numerous. Let me add that, with us at least, the epidemic may be considered as gone by now for a week or ten days: during the last week only two cases having been admitted for that disease.—I remain, sir,

Your obedient servant,

JOHN CLENDINNING.

Wimpole Street, Feb. 21, 1837.

Total of patients in the Marylebone Infirmary, Dec. 31, 1836	216
Total admissions, medical and surgical, between Dec. 30, 1836, and Feb. 10, 1837	465
Total treated in the Infirmary in the six weeks ending February 10, 1837	681
Total of deaths in the six weeks in the Infirmary	118
Of which belonged to the admissions of the year 1836	20
Leaving on the admissions of the six weeks ending February 10, 1836, deaths	98
Or a mortality on the admissions of ⁴⁶⁵ / ₉₈		= 22 per cent. nearly.

Anatomie der Mikroskopischen Gebilde des Menschlichen Körpers (Anatomia Partium Microscopicarum corporis Humani). Von Dr. JOSEPH BERRES, Professor der Anatomie an der Wiener Universität. Wien, 1836. Schloss.

WE have here a portion of a splendid work, which we foresee will have an extensive celebrity ere long, wherever medical science is cultivated.

Without anatomy there can be no physiology; this is now an old truth. But it is only comparatively recently that it has become generally acknowledged that there can be no rational account given of the functions of any part until the structure of its tissues is thoroughly known. Who, for example, would attempt to explain the action of the lymphatics in digestion without being familiarly acquainted with the texture of the parts, suitably injected and microscopically examined? Can the secretions of any membrane, gland, or organ, be even plausibly accounted for, without an accurate demonstration of the parts concerned?

The value of microscopic investigation has long been admitted; but not universally. The sceptics have always been in the majority: they have refused to believe what they had not themselves an opportunity of seeing; and in some instances they have refused to see what, if acknowledged as real, would overturn their theories.

Leeuwenhök, Ruysch, Lieberkühn, Prochaska, Spallanzani, and others, have left us admirable examples of what could be done by talent employed in this way, even with inferior instruments. But since their time much has been achieved. In our own day we have had a number of observers, whose discoveries will perhaps never pass into oblivion. Every physiologist is familiar with the names of J. Müller, Burdach, Ehrenberg, Purkinje, Weber, Krause, Breschet, &c. These distinguished explorers of structures have presented us with the results of their invaluable researches; but it must be confessed that when combined, their works do not

always exhibit uniformity or harmony with each other.

It is with a view to obviate this imperfection that Dr. Joseph Berres, the eminent Professor of Anatomy at Berlin, has undertaken to give a complete and uniform series of microscopic observations of the minute structures of the human body.

In a learned preface he develops his plans, and states his appliances and means. He tells us that his emulation was excited by the treasure of microscopical preparations which they possess at Vienna, from the hands of Lieberkühn, Barth, and Prochaska. With the compound microscope of Plössl (an artist whom he praises in the highest terms), he was enabled to appreciate the excellence of these, but at the same time to see that they were far from being perfect.

His present criterion of the excellence of a preparation suited for microscopical purposes is this—to be able to distinguish the anastomosis of all the vessels even in the minutest twigs, and to discern their perfect detachment or separation from the surrounding organic matter. Every vessel is to be traceable continuously and without interruption through its entire course. How he and his assistant Dr. Hyrtl manage to effect these exquisite preparations is fully explained.

We ought to state Dr. Berres' arrangement. He divides the work into three chapters.

In the first, which is introductory, he explains all that appears essential for the better understanding of the subsequent parts; every thing relating to the use of the instrument which he employs, and to the mode of instituting the observations with the best effect, is laid down for those who wish to verify the results themselves.

In the second, the minutiae of the various organs are microscopically explored, and the most prominent and important objects among them depicted and described. Those among them which seem to claim most attention as a surgical or physiological point of view, are dwelt on more particularly.

The third chapter is to contain a sort of digest of the materials collected. It will be an attempt to arrange, in a philosophical order, the numerous and wonderfully various observations, so as to

found upon them a fair induction, with as little risk as possible of any ill-concerted theory.

With respect to the instrument—the *Plösslische mikroskop*—used by Dr. Berres, it is figured in the first plate, and would not be considered by microscopists here as more than an ordinary instrument in its external appearance. It possesses four aplanatic eye-glasses, composed of two achromatic lenses each, and is furnished with six object-glasses, all of them achromatic and aplanatic. The power of enlargement commonly used by the Doctor is 110 diameters; but he frequently applies a power of 750, as in viewing the globules of the blood, and he says he can augment his magnifying power to double that number.

As an instance of the exaggeration which at no distant period was to be met with in describing the powers of instruments, the author tells us that he has in his possession Prochaska's microscope, which was said to magnify 400 times lineal measure; but upon examining it carefully, its powers are found not to exceed 28.

Each fasciculus contains two plates, fine specimens of the powers of lithography, with letter-press in German and Latin.

In the first plate we mentioned that the microscope is represented. The second is devoted to plexuses of minute veins and arteries, beautifully delineated in their principal varieties of form. The power here employed is 110 diameters.

Plate the third exhibits various vascular net-works, some of them seen by a power of 640 linear. In the fourth we have the elementary parts, such as the lymph vesicles, the globules of the blood seen under different aspects: they are shewn, by the way, to be flattish discs, not globules, and to have a central depression. The elementary vesicles of fat are also figured here. Osseous, horny, cartilaginous particles, are also displayed.

In plate five we have nervous, vascular, and muscular elements. The parts of muscular fibre are shewn at rest, contracted, and loosened into further filaments: the two former conditions are exhibited as seen with a power equal to 640 diameters; the latter with one of 750. Plates six and seven exhibit the skin and its elementary details. Eight

and nine, display the tissues connected with the organ of taste. Ten, exhibits miscellaneous textures, among them a vertical section of the kidney, exquisitely delineated. The eleventh and twelfth plates shew the structures connected with the organ of vision.

But the work requires to be seen and minutely examined, in order to be appreciated according to its merits.

The Works of John Hunter, F.R.S.; with Notes. Edited by JAMES F. PALMER. In 4 vols. 8vo. illustrated by a Volume of Plates, in 4to. Vol. I.

“FABER quisque fortunæ suæ,” is a maxim which those who have been successful in life are generally found willing enough to adopt, as it implies a compliment to their own discretion, and excludes fortune from any share of their success. The art of rising in life, however, is a compound game, consisting of chance and skill, in which chance is often found to over-rule the most consummate skill. “The battle is not always to the strong, nor yet favour to men of skill, but time and chance happeneth to all.” This is more especially true of medical men, who have always received the credit of being fully as dependent on the general affability of their manners and the lucky incidents of fortune, as on the skill and knowledge which they possess in their profession. For our parts, we see no reason to question the accuracy of popular belief on this subject, or to doubt that the avenues of fortune are as diverse in professional as they are in common life. In most respects, Hunter's entrance on his professional career was commenced under the most favourable auspices. He had studied under the ablest surgeons of the day, had associated with the most eminent characters of the age, and had acquired a considerable reputation for his anatomical knowledge; and yet the drawbacks inherent in his own character prevented his reaching to any great degree of popularity until a late period of his life, and would probably have restrained his flight beyond the vulgar bounds of mediocrity to the end of his days, had those days been a little less short than they were, or the powers of his intellect been a little less vigorous.

“Hunter was, however, destined to

undergo a long trial of those qualities of passive fortitude and active perseverance, of which few situations in life demand a larger share than that of a young man commencing practice in the higher branches of the profession of law or medicine in London; for assuredly it needs no small degree of fortitude to bear up against the disappointment a young man so placed must experience, in finding his merits overlooked, whilst the world is showering wealth on many around him whom he, at least, thinks far less deserving than himself. It requires, too, much steady perseverance, constantly to keep in view the destined goal; resisting the allurements which have so often led men of superior talents to desert the arduous contest, and devote themselves to the pursuits of literature or of science—pursuits which, though delightful, can seldom be extensively followed without the neglect of objects more essential to those who seek for fortune, as well as fame, from the practice of a profession.”

It may shrewdly be suspected that most of the events of life are the offspring of circumstances, and gradually grow out of one another. Historians and biographers commit a great error in ascribing the principal revolutions of public and private history to deep-laid schemes of policy; whereas, in truth, the difference in men's fortunes chiefly consists in the sagacity with which they seize, or the aptitude with which they turn to advantage, the common incidents of life. Some there are, indeed, in whose lives there is a sort of “tide, which, taken at the full, leads on to fortune;” but with the generality, life may more aptly be compared to the galaxy or milky way, which consists of clusters of innumerable stars, or to a river which is fed by innumerable small streamlets; the great secret of self-wisdom being to keep a steady eye to one's own advantage, and to turn the least circumstances to account; and, under due restraint, no one can object dishonour to this mode of proceeding, although nothing can be more contemptible than the base shifts to which some men resort, for the purpose of lifting themselves into public notice.

“ Hunter had also a great contempt for those minor tactics which constitute so large a part of what has been aptly called the act of rising in the world;

and they who have carefully watched the progress of men to fortune, know full well how much of their success has often been due to the judicious management of these auxiliary means. It would be egregious folly to suppose that a man could ever attain to high repute as a surgeon in London, without possessing a large share of the essential requisites for the practice of his profession; but, on the other hand, it requires no great penetration to perceive that the vast difference in the amount of her favours, vouchsafed by Fortune to her different votaries, must be accounted for in some other way than by the amount of professional talent possessed by each. ‘He that is only *real*, had need have exceeding great parts of virtue,’ says Bacon, ‘as the stone had need be rich that is set without foil;’ and we need not a better illustration of the truth of this observation than is afforded by Hunter's tardy progress to the path of fortune, compared with the rapid strides of others, who, in professional attainments, would be the first to acknowledge themselves but the humble disciples of this great master.

“ But after all, perhaps, the principal reason why Hunter was so long in obtaining a large share of practice, was, that he looked not, as most men do, to the acquisition of fortune, as the end for which he was labouring; but, on the contrary, considered wealth only as a means by which he might advance the far more important objects he had in view. His powerful mind was unceasingly stimulated by an ardent desire to forward the acquisition of those branches of knowledge which, to him, appeared best fitted to promote the improvement of his profession: to this object was devoted every hour that he could spare from his daily avocations, or snatch from the time allotted by others to sleep; and, to promote this end, he was always ready to sacrifice the claims of worldly prudence and self-interest. To witness an interesting and extraordinary case, he would take any trouble, or go almost any distance, without a chance of pecuniary recompence; but to the daily routine of practice he always returned unwillingly, and even when he had acquired a lucrative and extensive business, he valued it only as affording him the means of pursuing his favourite studies. This feeling he would often express to his friend.

Mr. Lynn, when called to see a patient, by saying, as he unwillingly laid by his dissecting instruments, 'Well, Lynn, I must go and earn this d——d guinea, or I shall be sure to want it to-morrow.'

During the interval which occurred between Hunter's return from the Peninsula and his extensive private engagements in business, he was compelled to eke out his slender fortune by receiving pupils into his house. Most of these attained to considerable eminence in their profession in after life; thus proving the excellence of the instructions which they received under his roof, and the zeal with which his example was able to inspire them. The following just reflections occur on this subject:—

"All of these gentlemen have risen to high reputation in their various stations, and it is not unworthy of remark, that, of the eminent surgeons of which this country has had to boast, by far the greater number have pursued the most important part of their professional education under the roofs, and as the private pupils, of the most able of their predecessors in the art. This may, no doubt, in some cases be accounted for by supposing that the disciple had previously shewn such talent as to lead his friends to seek the best situation for its improvement; but more has been probably due to the stimulus imparted to their energies by the examples before them, and still more to the advantages derived from daily witnessing the best modes of practice, and receiving information on those nicer distinctions in treatment which can never be fully conveyed in lectures, but the knowledge of which forms a distinguishing mark of the accomplished surgeon. Thus we find that most of the surgeons who, in the present day, enjoy the largest share of the public confidence, are, as it were, the direct mental descendants of the men who, a century ago, introduced the first important improvements into modern surgery. Cheselden, Nourse, and Douglas, were then the leaders of our profession; of whom Sharp, Pott, and the Hunters, were the immediate pupils. They, again, became the instructors of Cline, Lynn, Home, Abernethy, Carlisle, Macartney, Sir James Earle, and Cooper; and from them the mantle has descended to a Brodie, a Lawrence, a Green, an Earle, and others, who now

occupy, with so much credit to themselves, the places which their great predecessors adorned."

Among Mr. Hunter's pupils, none appears to have won so much on his affections as Dr. Jenner, with whom he ever afterwards maintained a friendly and cordial correspondence. Perhaps no part of Mr. Hunter's history exhibits in so striking a light the untiring ardour with which he prosecuted his physiological pursuits, as this correspondence. As models, indeed, of epistolary composition, we are compelled to say that they are deficient in that ease and fluency which constitute the chief charm of this style of writing, but they every where evince the vigour and originality of his thoughts, while his expressions are often characterized by great terseness and force. We quote a couple of these letters as specimens of the rest.

"Dear Jenner,—I own I was at a loss to account for your silence, and I was sorry at the cause. I can easily conceive how you must feel, for you have two passions to cope with, viz. that of being disappointed in love, and that of being defeated; but both will wear out,—perhaps the first soonest. I own I was glad when I heard you was married to a woman of fortune; but 'let her go, never mind her.'

"I shall employ you with hedge-hogs, for I do not know how far I may trust mine. I want you to get a hedge-hog in the beginning of winter, and weigh him; put him in your garden, and let him have some leaves, hay, or straw, to cover himself with; which he will do. Then weigh him in the spring, and see what he has lost. Secondly, I want you to kill one in the beginning of winter, to see how fat he is; and another in spring, to see what he has lost of his fat. Thirdly, when the weather is very cold, and about the month of January, I could wish you would make a hole in one of their bellies, and put the thermometer down into the pelvis, and see the height of the mercury; then turn it upwards towards the diaphragm, and observe the heat there. So much at present for hedge-hogs. I beg pardon,—examine the stomach and intestines.

"If Hewson's things go cheap. I will purchase some that I think good for you; those you mention will, I

afraid, be every body's money, and go dear.—Ever yours,

“J. HUNTER.”

(Postmark, Jan. 29, 1789.)

“Dear Jenner,—I wish you joy: it never rains but it pours. Rather than the brat should not be a christian I will stand godfather, for I should be unhappy if the poor little thing should go to the devil because I would not stand godfather. I hope Mrs. Jenner is well, and that you begin to look grave now you are a father.—Yours sincerely,

“J. HUNTER.”

Besides an Appendix at the end of the Life, containing a chronological list of Mr. Hunter's writings, the author has, in the course of his history, interwoven an account of these various productions, accompanied in most cases with some judicious reflections on their nature and value. The following, on the work on Inflammation, are well deserving of consideration:—

“This work is the one on which, above all his other writings, Hunter's fame has hitherto rested, perhaps too exclusively so, since it has arisen from the circumstance that, with the exception of the Treatise on Syphilis, his other works have been less generally read than they deserve, in consequence of having been published either in an expensive form, or in detached treatises, scattered through the volumes of the Philosophical Transactions, or of the Medical and Chirurgical Society. There are not, however, any of his writings which do not well deserve the attentive perusal of professional men, not only for the information they furnish, but as models of bold and sagacious reasoning; and hence the present edition, which places within the reach of every professional man the whole of his works, heightened, too, in value, by the commentaries of the able men to whose revision they have been severally entrusted, cannot fail to be viewed as a tribute justly due to the merits of Hunter, and as a highly important accession to our medical literature.

The treatise on Inflammation and Gun-shot Wounds must be considered as comprising the results of forty years, assiduous attention to the subject, since from his introduction we learn, that the doctrines it unfolds first suggested them-

selves to his mind at the time he was a student in the London Hospital, and were based on observations collected during that period. These doctrines he continued during his whole professional career to submit to the test of his own increasing experience, and the experience of others, to whom he taught them in his lectures, ever carefully and candidly correcting them where more accurate observations proved them to be faulty, and extending them where fresh information shewed them to be deficient; and having thus brought them to as high a degree of perfection as his abilities and opportunities would permit, he at length submitted them to the test of public opinion in the condensed and systematic form in which we now possess them. Notwithstanding the time and attention he had devoted to the completion of a work on which his future fame was mainly to depend, he was himself fully sensible of its still possessing many defects, and rather desired it to be considered “as a new figure composed from rough materials, in which process little or no assistance could be had from any quarter,” than as a perfect work which no farther experience could have amended. It must, indeed, be acknowledged that it does, in many parts, exhibit imperfections of style and diction, as well as repetitions, which not unfrequently obscure the author's meaning; and illogical errors, such as that of confounding proximate and final causes, or employing such imaginary causes as the “stimulus of necessity,” “the stimulus of death,” “the force of a negative impression,” &c., to account for certain effects; phrases which cheat the ear with a seeming explanation, but leave the mind no whit the wiser as to the real causes of the phenomena to be accounted for. These defects, though they do unquestionably detract somewhat from its value, are, however trifling in comparison with the great and varied excellence of this work, which, for the originality and variety of its experiments, the accuracy of its observations, and the importance of its deductions, can with difficulty be paralleled in the whole range of medical literature.

As an instance of the zeal with which Hunter sought and procured every object of curiosity calculated to enrich his museum, the following is sufficiently interesting:—

"The late Dr. Clarke had a preparation of an extra-uterine pregnancy, in which the fœtus had been detained in the fallopian tube, and had there undergone partial development, when the mother died from internal hæmorrhage, consequent on the rupture of the tube. On this specimen he set a high value, and Hunter had often viewed it with longing eyes. "Come, Doctor," said he, "I positively must have that preparation." "No, John Hunter," was the reply, "you positively shall not." "You will not give it me, then?" "No." "Will you sell it?" "No." "Well, then, take care I don't meet you with it in some dark lane at night, for if I do, I'll murder you to get it."

We pass over Sir Everard Home's atrocious conduct in burning the Hunterian MSS. with this single observation, that as the Venetians have placed a black tablet in the place of the portrait of their traitor doge, so a black tablet in the Hunterian Museum would be a fitter record of Sir Everard Home's baseness than the bust which at present stands in the hall of the College. "O tempora! ô mores! Senatus hæc intelligit, consul videt: hic tamen vixit; vixit? imò verò etiam in senatum venit."

We conclude with the following extract, which contains a hint which we hope to see acted upon before many more years have elapsed.

"It may be thought that the author of the Hunterian Museum needs no other memorial of his worth than the proud one he has himself erected; nor does he, to perpetuate his fame: still, it would be a fitting act of respect to his memory, from those who enjoy the benefits of this rich legacy of his genius, to enrol his name amongst those of the other gifted men whose worth stands recorded in Westminster Abbey."

DESGENETTES.

WHEN the French were at Moscow, the Emperor gave an order to have the Foundling Hospital converted into a barrack; but Desgenettes, as bold in Russia as formerly in Syria, told him to take care how he allowed posterity to compare him with Herod. "Herod!" said Napoleon, "what resemblance is there between me and Herod; what do you allude to?"—"To the massacre of the innocents!" replied Desgenettes. The order for the barrack was countermanded.—*Bouillaud's Éloge.*

MEDICAL GAZETTE.

"Licet omnibus, licet etiam mihi, dignitatem Artis Medicæ tueri; potestas modo veniendi in publicum est, dicendi periculum non recuso."

CICERO.

MEDICAL ATTENDANCE

ON

PAUPERS UNDER THE POOR-LAW.

WE make no apology for once more calling the attention of our readers to this important subject. Notices of motions have been given in Parliament for committees to inquire both into the general and medical working of the amended Poor-Law, and every man who possesses a spark of national feeling ought to take an active interest in the result.

Medical men are more especially implicated in the consequences; for if the Poor-Law be allowed to continue in its present state, it must entail permanent disgrace and degradation on the profession.

Three things are loudly complained of by those practitioners in the provinces who have the best opportunity of observing the operation of the Union system; these are, first, the utter insufficiency of medical attendance on the pauper population; next, the miserably wretched remuneration which the district medical officers (or slaves rather) are obliged to accept; and, lastly, the perpetual insults and indignities cast upon the members of the profession by the Poor-Law functionaries—who no doubt calculate that if they can only lower medical practitioners in the public estimation, they can then accomplish their purposes of thrift and meanness with perfect certainty of success.

These are no vague and groundless assertions; they are facts proved over and over again in the pages of this journal, but not the less worthy of repetition for that reason. Medical men

often require to have their memory jogged, and to have the same truths reiterated occasionally before the requisite impression is made. At the present moment every medical man should be broad awake; and not only individuals of the profession, but the corporate bodies, should be up and stirring, if the character of the healing art be in any way dear to them.

The active Committee of the Provincial Association have just put forth a second edition of their valuable report*; to that summary of the state of the case between the Poor-law and the medical profession, we strongly recommend at this juncture the attention of the Colleges, the Hall, and every individual practitioner; even the most cursory perusal of its contents must convince the reader how deeply the interests of medicine are involved in the proper adjustment of the question.

On a former occasion we noticed the body of the Report, and made some extracts from it; we have not much space at our command just now, or we should be tempted to select some more, especially from the fresh matter incorporated with the new edition. There are a few passages, however, for which we must make room, as they shew in a striking manner the difficulties in which many of our unhappy brethren in the provinces are placed under the existing régime.

For those who are trammelled in the new arrangements to speak out, or to complain in any manner of their grievances, were as much as their frail tenures are worth; it would be deemed a sort of high treason to the Somerset House authorities, and, if discovered, would be summarily dealt with. The following

letter sent to the Committee will serve to show how even medical men not immediately connected with the Union are situated:—

"Though the statement I gave you dated October 23rd, is decidedly correct, and I could undertake to prove it in every particular, yet, situated as I am at the present time, it might be extremely injurious to me if I allowed that statement to be published, knowing that it came from me. In the first place, the Vice-chairman of the union is a most excellent patient of mine, and thinks very highly of the New Act, and *perhaps that statement might displease him*; if it did, the mischief might not end there; *he could influence others*. Again, would not that statement be a libel on the district medical man, and therefore actionable, so that I might be dragged into law proceedings. I can have no objection to the statement being published, if neither name nor place be mentioned. I have every wish to render the Committee all the information I possibly can, but having a family to provide for, and entirely dependent on my exertions, *I do not think I ought to risk any thing*.

"I feel equally with the Committee, the DEGRADATION brought on the profession by the Poor Law Commissioners, and nothing would give me greater pleasure than to assist my medical brethren, in any way I can, to extricate us from it.—I am, &c. &c.

"Dec. 13, 1836."

At the conclusion of the present article we shall give a similar letter just received by ourselves, in which the working of the same degrading influences will be recognized.

We have alluded to the insufficiency of the medical aid provided for ~~un-~~paupers in the keeping of the Commissioners. Who can read the following facts without being convinced of the mischievous tendency of their present arrangements.

"In the Cookham and Bray unions, two medical men were appointed under the new system, in place of seven who previously attended.—In the Newbury union, consisting of eighteen parishes

* The Report of the Poor Law Committee appointed by the Provincial Medical and Surgical Association. Read at the Anniversary Meeting, held at Manchester, July 1836. Second Edition, with an Appendix, containing Selections from the Evidence furnished from numerous Parochial Unions, respecting the Medical Arrangements and their Effects.

one individual undertook the duties formerly performed by *twelve*; he had no assistant, and had a space to ride over measuring sixteen miles by ten.—In the Bampton district of the Witney union, *ten* miles in diameter, *eight* medical men were formerly employed; now only *one*.—In one of the districts of the Aylesbury union, the surgeon resides at a distance of *seven* miles from one part of the district, where medical assistance might be obtained within *two* miles.—In another district of the same union, the nearest point to the surgeon's residence is *seven* miles, and the most remote *twelve*. Under the old system *sixteen* medical men were employed for the parishes of this union, containing forty parishes and four districts; under the new system *three* medical men only, one of whom was likewise appointed to an extensive district in another union.—In the Wheatenhurst union, comprehending *fourteen* parishes, and necessarily much travelling, the Commissioners induced the Guardians to waive a contract with the established practitioners, and to engage *one* young man from the schools, who had neither a horse nor instruments.—In the Faversham union, including twenty-five parishes, only *one* medical man was employed.—Numerous cases of a similar kind could be adduced.”

As to the proofs of the degradation suffered by practitioners who have the misfortune to be connected with the existing Poor-law unions, they abound in the Report. The subjoined passages are among the conclusions on the subject drawn by the Committee:—

“ Medical officers are liable, in the discharge of their duty, to receive a summons from the Board of Guardians on occasion of any supposed neglect; they are thus subject to be reprimanded by persons who cannot be supposed capable of judging correctly as to the due performance of medical duties. Your Committee have received information of several oppressive proceedings of Guardians in this respect.

“ Again, if a medical opinion is considered necessary to guide the Board in any of its deliberations, which not unfrequently occurs, the medical officer is summoned to attend in the same man-

ner as are the inferior officers of the Board.

“ Lastly, those medical men who have presumed to express an opinion unfavourable to the new medical arrangements, have frequently been marked for oppression by the authorities, and some have even been induced to withdraw or withhold their names from petitions to parliament against the system, from apprehension of injurious consequences to themselves.”

The meanness of the Commissioners in taunting medical men with accepting (what in many instances they cannot help) appointments by *tender*, when they themselves arbitrarily dictate this as the sole mode of obtaining an appointment in certain localities, is well exposed by the Committee. The Commissioners say, “ We may be sure that the medical practitioner will, in fixing upon his terms, do nothing which he considers will not, on the whole, be advantageous to his own profession;” thus endeavouring to cast solely on the medical officers of Unions the discredit of the miserably low stipends awarded to them. But, say the Committee, with excellent good temper and pointed shrewdness,—“ We have only to reply, that were the system of *tender* introduced into any other profession, the same injurious results would ensue; if even the office of the Poor-Law Commissioner were to be submitted to the same degradation, there would be found needy speculators, not destitute of ability, who would gladly, for the tenth part of the salary, undertake its duties.”

We intended to have noticed some of the facts in the Appendix, but find we have only room to give the letter we promised.

To the Editor of the Medical Gazette.

SIR,

THE following very singular and offensive note was received, a few days ago, by a respectable practitioner in

this neighbourhood from a relieving officer:—

“Sir,—You are requested to attend to the case of S. G. *immediately*, who is said to be in a state of mental derangement. You are also requested to call on the overseer (i. e.) Mr. M., and report the case to him, that he may report the same to-morrow at the Board at C——. (*Fail not at your peril.*)
“W. C., Relieving Officer.”

It was sent to me as affording an additional proof of the degradation to which the profession are subjected under the operation of the present abominable system. If you think its publication will operate as a wholesome lesson to those members of the profession who are so anxious to fill the *highly respectable*(?) office of medical officer under a Board of Guardians, as to tender their services for a wretched pittance, you will oblige me by giving it insertion.

As the case is also an admirable specimen of the medical merits of this wonder-working system, I cannot forbear mentioning it.

A poor widow, *æt.* 47, whilst washing in the house of the *overseer* of her own parish, is taken ill on the Monday; she gets worse on Tuesday and Wednesday; is in a state of violent derangement on Thursday (no doubt arising from active disease within the head); persons are employed by the overseer to take care of her both day and night, and yet, sir, she was allowed to remain without medical assistance until the following Monday, *one week* after the commencement of this serious attack, when a humane gentleman in the neighbourhood, hearing of the case, sent a surgeon to attend her at his own expense. On the following day (Tuesday) the relieving officer pays his *weekly* visit to the parish, and by way of making up for the previous neglect, sends the above-mentioned insolent note to the medical officer, who in duty bound immediately attends, and on his arrival finds the poor woman already under the care of another practitioner as a private patient, by whom she had been bled, leeches, blistered, head shaved, and physicked! She has since died.

It is but justice, however, to the Board of Guardians, to state, that when the case was brought before their notice, they reprimanded their officer, and passed a resolution unanimously de-

claring their disapprobation of his conduct.—I am, sir,

Your most obedient servant,
A CONSTANT READER.

Cerne, Feb. 20, 1837.

P. S. I send you my name in confidence, as I do not think any communication of this sort should be sent without it, but I do not wish it to appear in public.

ROYAL INSTITUTION.

Friday, Feb. 17, 1837.

Dr. Marshall Hall's Reflex Action of the Spinal Marrow.

DR. FARADAY undertook this evening to give a popular exposition of Dr. Hall's views on the “reflex function,” and effected it with brilliant success. He apologized for meddling with a subject so strictly physiological and out of his province; but it was one of the objects of these evening meetings to bring even the most abstruse topics familiarly before the members of the Institution and their friends. After pointing out the functions of the brain, and showing, in accordance with Dr. Hall's theory, that the brain is the sole seat of sensation, he passed to the consideration of the spinal cord and its reflex action. It would be superfluous in this journal, in which Dr. Hall's views have so often been stated, to repeat the account given of them by Dr. Faraday, of which not its novelty but its total freedom from technicalities was the principal charm. Dr. Hall's experiments on the turtle, the snake, the frog, the stunned horse, &c., were described; and diagrams were exhibited which were well adapted to give a general idea of the subject to a popular audience.

The views of other writers corroborative of those of Dr. Hall were alluded to. Mr. Mayo's distinct notice, in a book of his published in 1823, of the identical function of the spinal marrow, so fully afterwards developed by Dr. Hall, was quoted; and Dr. John Müller's opinions, as given in his *Physiology*, were stated to be strongly confirmatory of the same doctrine.

By the way, we have before us an extract from Müller's account of the reflex function, recently published by Dr. Hall, with remarks; we cannot, perhaps, do better than close this brief account of a very interesting evening with the summary given by Dr. H. of those points in which he differs, to a certain extent, from Professor Müller:—

I view the reflex function as the *et* and *peculiar* or *proper* function of the medulla spinalis, equally independent of the brain, the sympathetic, and of the somatoses and the mere origins of the reflex;

I regard this function as residing in the medulla, as the *axis* of a *distinct* system of *excitor* and *motor*, and *excito-motory* functions;

I consider this function and its system of nerves as presiding over the *orifices* of the *exits* or *sphincters* of the animal body, and over *ingestion* and *egestion*;

The brain is the central organ of sensation and volition, the organ of *mental* communication with the external world; the spinal marrow, on the contrary, is the central organ of excito-motory phenomena, of the *physical* appropriation of certain external objects;

Respiration even is a part of this peculiar function: it is *excited* on ordinary, and on extraordinary occasions, through appropriate excitor nerves, especially the pneumo-gastric, but also the fifth and vagus nerves;

Volition may *modify* the acts of the reflex function, and these acts may be modified by sensation; but this function is otherwise, independent both of volition and sensation, of their organ the brain, and of the mind or soul;

The *passions*, in an especial manner, manifest themselves through the medium of the true spinal marrow; and thus may induce surprise or fear, and *appear* as *causes* of excito-motory act;

The brain *sleeps*; but the spinal marrow *never sleeps*;

Finally, the excito-motory system of nerves are the peculiar seat of action of the reflex in *diseases*, and of certain *causes* and *effects* of disease.

IN CAPTANDUM SURGERY.

INDIFFERENCE for certain operations, and a want of over-zeal in seeking for occasions to perform them, are modern traits of professional character, which, it is to be feared, will become obliterated or obscured by the daily improvements in pathology and the diagnosis of diseases. The mere reputation ought not to be ranked amongst the merits of surgeons, and the kidnapping of patients as furnish conspicuous motives for an hospital-theatre, or for the private assembly of a coterie of young physicians, should be discountenanced and repressed by every conscientious cultivator of surgical science.—*Mr. Crosse's Retrospective Address.*

HOSPICE DE LA MATERNITÉ, ARRAS.

CÆSAREAN OPERATION SUCCESSFULLY PERFORMED, WITH SAFETY BOTH TO THE MOTHER AND CHILD.

By A. R. DUCHATEAU, M.D.

Surgeon in Chief to the Hospitals of Arras, Professor in the School of Medicine, &c.

STEPHANIE BRASSART, aged 22, is a native of Arras. Her parents were both well formed; her height is forty-three inches; her general aspect that of a rickety person. The vertebral column is very convex anteriorly; the thighs are short, and the legs much curved. General health good on entering the hospital.

We learned that the catamenia had made their first appearance when she was 18 years of age, and had continued abundant and regular since. The first time I saw her at the Maternité, whither she came in order to be let blood, in the eighth month of her first pregnancy, I was struck with her figure, and thought it requisite to make some inquiry as to the state of the pelvis. Mde. Delarue and I instituted an examination accordingly, and found that the crests of the ilia were in one line, and that from one anterior superior spinous process to the other measured 8 inches 9 lines; also that the sacro-vertebral angle was directed towards the pubes, and a little to the right, and that the upper strait was but two inches in its antero-posterior diameter.

On the 20th of April, 1836, Stephanie returned to the hospital, being at her full time; she complained of pains about the loins. No regular labour-pains, however, occurred till five in the morning of the 24th, when they came on decidedly but slowly. At six, the os uteri might be felt turned to the right and forward, with a dilatation of from 10 to 12 lines. The membranes now began to present, but no part of the child could be reached in any way by the finger. A lavement was administered, and the patient put into a bath.

A meeting of my colleagues was summoned, and assembled at nine A.M., when all were satisfied that the Cæsarean operation was indispensable. The patient was taken, without loss of time, into the operating theatre, and there, in presence of the civil and military *officiers de santé* of the hospital, Mde. Delarue, and our pupils

of the Maternité, and upwards of sixty pupils belonging to the school, I had Stephanie placed on a hair mattress, with her body horizontal, her head slightly raised, and her lower extremities a little apart—the feet being on the margins of the bed. My four assistants being duly appointed to their several posts, I took up my position on the left of the patient, when I commenced by making an incision on the abdomen, extending from two inches above the pubes, along the linea alba, a little to the left, avoiding the umbilicus, to two and a half inches above the navel. In completing this incision, the several aponeurotic expansions were laid bare. The peritoneum was at length arrived at, when it was opened with great caution by means of a straight and buttoned bistoury, along the whole length of the original incision. I then raised the omentum which covered the uterus and intestines; an assistant kept it raised; upon which the uterus was found having its centre in the middle of the incision of the abdomen. I cut into it with a slightly convex bistoury, when the fibres of the womb were observed separating from each other as fast as they were divided. As soon as I reached the interior surface, I found by the jet of black blood which immediately took place, that I had cut down on the placenta. The opening was forthwith dilated with a buttoned bistoury; the membranes were then seen, upon which I opened them cautiously, the assistants taking care that the liquor amnii should not be effused into the cavity of the abdomen. The infant was in the first position for delivery; I withdrew it by the legs, supporting the trunk with the left hand; it cried presently, and the funis was divided. Mde. Delarue took charge of the child; it was a boy, and weighed 6 lb 4 oz.

We then waited for three minutes, when finding the uterus contracting, I detached the placenta, and removed it along with the membranes; nor were there any clots of effused fluid left in the viscus. I put my forefinger through the os tincæ from within, and met the finger of one of my assistants from without: we were thus satisfied that there was no mechanical obstacle to the lochia, should they occur; we also ascertained that the structure of the promontory was such as we judged it to be when we determined on the operation.

The borders of the abdominal incision were brought together with three points of suture. A seton covered with cerate was placed at the lower angle of the wound; five pieces of sticking-plaster were placed between the sutures; a compress was laid over this; and charpie, with a general

bandage methodically applied, completed the process of dressing.

The operation lasted altogether about twenty minutes. No artery that required tying was divided. The patient during the whole of the time displayed much fortitude and resignation. After the operation she was removed to another bed on the same floor, where she was placed in a horizontal position and left to repose, after getting a sedative draught.

About three hours after the operation acute pains were felt in the right iliac region, which required the application of fifteen leeches. This had a good effect. Vomiting and feverish symptoms during the afternoon. On the second day, the vomiting continuing, with much disturbance of the system, the dressing was removed, when a portion of the omentum was found protruding at the upper angle of the wound; it was returned into the abdomen, and secured there by adhesive plaster laid above its place of egress. A large poultice was applied to the abdomen, which alleviated the vomiting and pain.

Third day.—The lochia are established; the disturbance of the system much abated; the bowels largely moved. Poultice renewed. The symptoms were variable during the succeeding days, but not alarming at any time.

Ninth day.—Total absence of fever; wishes for *café au lait*, which is given her. Sutures and seton removed. Union of a great part of the wound; a little pus, however, flows from the lower angle on the accession of cough. The poultice still applied daily.

From the tenth to the twenty-first day, when the cure was complete, the dietary regimen was gradually improved: all the functions were naturally performed. An appearance of œdema was noticed about the fifteenth day, but was remedied by medicinal treatment. After this Stephanie began to leave her bed, and to walk about the wards, and in the garden of the hospital. She did not return home till sixty-three days after the operation, having waited, indeed, to be present at the distribution of prizes which took place at the Maternité on the 25th June.

The child is well; it has been sent out to nurse at the charge of the administration of hospitals, the mother having had no secretion of milk*.

LECTURES

ON

MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

By JON. PEREIRA, Esq., F.L.S.

LECTURE LVIII.

IN my last lecture I commenced the examination of the family Menispermaceæ, and noticed the *Cocculus palmatus*, which yields us Calumba root. I shall in the next place examine

Cocculus suberosus.

History.—According to Sprengel, the fruit now usually called *Cocculus indicus* was introduced by the Arabians, and was described by Avicenna and Serapion under the name of *Maheradsch*. It is sometimes termed the *Levant nut*, or *bacca orientalis*.

Botanical history.—The plant yielding it is a native of Malabar, and is called, by Linnæus, *Menispermum Cocculus*, by Wight and Arnott, *Anamirta Cocculus*, and by Decandolle, *Cocculus suberosus*. It is a dioecious, perennial, twining plant, with a corky cortex, leaves cordate, truncated at the base, firm and lucid. The inflorescence is a many-flowered panicle. The plant belongs to class *Dicæcia*, order *Herandria*, in the Linnæan arrangement.

The fruit is by some called a berry, by others a drupe. It is reniform, purplish red, and fleshy.

Physical characters.—As met with in commerce, *Cocculus indicus* is rather larger than a pea, rounded, or slightly reniform. It consists externally of a dried, thin, blackish brown, rugous, acrid and bitter layer, which envelopes a thin, bivalved,

white, ligneous shell. If the fruit be regarded as a drupe, the shell will be formed of the endocarp, and no seed coats will be recognizable: whereas, if the fruit be considered as a one-seeded berry, the shell must consist of two altered seed coats. In the middle of this shell arises a central placenta, which is contracted at its base, but enlarged and divided into two cells superiorly. Between this placenta and the shell is an oleaginous, yellowish, very bitter nucleus, of a semilunar form. This nucleus never wholly fills the cavity of the shell,—at least in the *Cocculus indicus* of commerce; for by keeping it gradually becomes atrophied, and in old samples it is not uncommon to find the shell almost empty. This change is observed also in other oleaginous seeds.

Chemical composition.—Iodine colours the nucleus brown. The cold watery infusion of the whole fruit is slightly acid, and produces a dark grey precipitate with chloride of iron. Infusion of galls feebly precipitates it.

Boullay made an analysis of *Cocculus indicus* in 1812, and in the year 1834, another analysis was made by MM. Pelletier and Couerbe.

1. **Analysis of the nucleus.**—The following are the substances recognised by MM. Pelletier and Couerbe in the nucleus of *cocculus indicus*.

1. Picrotoxine.
2. Resin.
3. Gum.
4. A fatty acid substance.
5. An odorous matter
6. Malic acid.
7. Mucus.
8. Starch.
9. Lignin.
10. Malate of lime.

Delivered at the Aldersgate School of Medicine,
By JON. PEREIRA, Esq., F.L.S.

LECTURE LVIII.

In my last lecture I commenced the examination of the family Menispermaceæ, and noticed the *Cocculus palmatus*, which yields us Calumba root. I shall in the next place examine

Cocculus suberosus.

History.—According to Sprengel, the fruit now usually called *Cocculus indicus* was introduced by the Arabians, and was described by Avicenna and Serapion under the name of *Maheradsch*. It is sometimes termed the *Levant nut*, or *bacca orientalis*.

Botanical history.—The plant yielding it is a native of Malabar, and is called, by Linnæus, *Menispermum Cocculus*, by Wight and Arnott, *Anamirta Cocculus*, and by Decandolle, *Cocculus suberosus*. It is a dioecious, perennial, twining plant, with a corky cortex, leaves cordate, truncated at the base, firm and lucid. The inflorescence is a many-flowered panicle. The plant belongs to class *Diatia*, order *Hexandria*, in the Linnæan arrangement.

The fruit is by some called a berry, by others a drupe. It is reniform, purplish red, and fleshy.

Physical characters.—As met with in commerce, *Cocculus indicus* is rather larger than a pea, rounded, or slightly reniform. It consists externally of a dried, thin, blackish brown, rugous, acrid and bitter

white, ligneous shell. If the fruit be regarded as a drupe, the shell will be formed of the endocarp, and no seed coats will be recognizable: whereas, if the fruit be considered as a one-seeded berry, the shell must consist of two altered seed coats. In the middle of this shell arises a central placenta, which is contracted at its base, but enlarged and divided into two cells superiorly. Between this placenta and the shell is an oleaginous, yellowish, very bitter nucleus, of a semilunar form. This nucleus never wholly fills the cavity of the shell,—at least in the *Cocculus indicus* of commerce; for by keeping it gradually becomes atrophied, and in old samples it is not uncommon to find the shell almost empty. This change is observed also in other oleaginous seeds.

Chemical composition.—Indine colours the nucleus brown. The cold watery infusion of the whole fruit is slightly acid, and produces a dark grey precipitate with chloride of iron. Infusion of galls feebly precipitates it.

Boullay made an analysis of *Cocculus indicus* in 1812, and in the year 1834, another analysis was made by MM. Pelletier and Couerbe.

1. **Analysis of the nucleus.**—The following are the substances recognised by MM. Pelletier and Couerbe in the nucleus of *cocculus indicus*.

1. Picrotoxine.
2. Resin.
3. Gum.
4. A fatty acid substance.
5. An odorous matter
6. Malic acid.
7. Mucus.
8. Starch.
9. Lignin.
10. Malate of lime.

11. Inorganic salts (nitrate and sulphate of potassa, and chloride of potassium) by incineration yield carbonates of potash, and of lime, manganese and iron.

**NOTE FROM MR. FERRIER,
OF YARMOUTH.***To the Editor of the Medical Gazette.*

SIR,

HAVING made your journal the medium of circulation for the railings of Mr. Aldred, of this place, against myself, an individual of whom you can have no knowledge*, I claim so much of editorial courtesy from you as will prompt you to insert this my reply, with which I should have troubled you before, had I not been much and severely occupied of late.

In answer to your comments, and Mr. A.'s letter, I beg to say, I am the correspondent of no individual journal, and feel myself at liberty to reply to the application of one journalist without becoming the object of unmerited abuse from another. I beg to reiterate my former statement, and at the same time I unhesitatingly place my character for veracity (which no abuse of Mr. A.'s can injure or destroy) upon the truth of every word thereof; and, in furtherance and proof of such statement, I beg to refer to the clerk of the peace, the clerk to the magistrates, and the officers in court, who were present at both the inquest and the previous interview with Mr. A. to which I alluded.

Were the circulation of your journal confined merely to the locality in which your original correspondent and myself reside, I would not thus trouble you.

I am, sir,

Your obedient servant,

WM. S. FERRIER,

Coroner of Great Yarmouth, and Senior
Surgeon to the Dispensary.Great Yarmouth, Norfolk,
Feb. 20, 1837.**DESGENETTES.**

It was in his tent at Acre, that Bonaparte suggested to Desgenettes the propriety of despatching his plague patients with opium: nor did the noble refusal of the latter turn the general from his purpose; he soon found others more compliant. "On our return to Jaffa," says Desgenettes, "I found that laudanum, in a strong dose, had been administered to about five-and-twenty or thirty of the sick. Some of them vomited it, were relieved, recovered, and then told what happened."

LITERARY ANNOUNCEMENT.

Preparing for publication on or before the 1st of October, **EXPERIMENTAL PHY-**

* Mr. Ferrier will excuse us. Who does not know the Medical Coroner of Yarmouth? Mr. Aldred's letter, by the way, was published on the 10th of last December.

SIOLGY; founded on *Land's Physiologische Resultate der Vivisectionen neuerer Zeit*; with considerable additions. By R. B. Todd, M.D. Professor of Physiology in King's College.

CHARLES HENRY ADAMS.

NOTICES.

The letter from the **BRITISH MEDICAL ASSOCIATION**, sent through their Secretary, is unsuited for our columns; we shall publish it *extra-limites*, if the parties please, or it may go on our wrapper as an advertisement. But no doubt Mr. Wakley, their patron, will be delighted to publish it for them; or Dr. Ryan, who "entreats the well-wishes of the British Radical Association." (See his No. for Feb. 11th.)

MR. SANDALL's article on *Spillan's Translation* of the Pharmacopœia is inadmissible: were it on the Pharmacopœia itself, we might be induced to give it insertion.

MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, Esq., F.L.S.

LECTURE LVIII.

IN my last lecture I commenced the examination of the family Menispermaceæ, and noticed the *Cocculus palmatus*, which yields us Calumba root. I shall in the next place examine

Cocculus suberosus.

History.—According to Sprengel, the fruit now usually called *Cocculus indicus* was introduced by the Arabians, and was described by Avicenna and Serapion under the name of *Maheradsch*. It is sometimes termed the *Levant nut*, or *bacca orientalis*.

Botanical history.—The plant yielding it is a native of Malabar, and is called, by Linnæus, *Menispermum Cocculus*, by Wight and Arnott, *Anamirta Cocculus*, and by Decandolle, *Cocculus suberosus*. It is a dioecious, perennial, twining plant, with a corky cortex, leaves cordate, truncated at the base, firm and lucid. The inflorescence is a many-flowered panicle. The plant belongs to class *Dicæcia*, order *Herandria*, in the Linnæan arrangement.

The fruit is by some called a berry, by others a drupe. It is reniform, purplish red, and fleshy.

Physical characters.—As met with in commerce, *Cocculus indicus* is rather larger than a pea, rounded, or slightly reniform. It consists externally of a dried, thin, blackish brown, rugous, acrid and bitter layer, which envelopes a thin, bivalved,

white, ligneous shell. If the fruit be regarded as a drupe, the shell will be formed of the endocarp, and no seed coats will be recognizable: whereas, if the fruit be considered as a one-seeded berry, the shell must consist of two altered seed coats. In the middle of this shell arises a central placenta, which is contracted at its base, but enlarged and divided into two cells superiorly. Between this placenta and the shell is an oleaginous, yellowish, very bitter nucleus, of a semilunar form. This nucleus never wholly fills the cavity of the shell,—at least in the *Cocculus indicus* of commerce; for by keeping it gradually becomes atrophied, and in old samples it is not uncommon to find the shell almost empty. This change is observed also in other oleaginous seeds.

Chemical composition.—Iodine colours the nucleus brown. The cold watery infusion of the whole fruit is slightly acid, and produces a dark grey precipitate with chloride of iron. Infusion of galls feebly precipitates it.

Boullay made an analysis of *Cocculus indicus* in 1812, and in the year 1834, another analysis was made by MM. Pelletier and Couerbe.

1. *Analysis of the nucleus.*—The following are the substances recognised by MM. Pelletier and Couerbe in the nucleus of *cocculus indicus*.

1. Picrotoxine.
2. Resin.
3. Gum.
4. A fatty acid substance.
5. An odorous matter
6. Malic acid.
7. Mucus.
8. Starch.
9. Lignin.
10. Malate of lime.

11. Inorganic salts (nitrate and sulphate of potassa, and chloride of potassium) by incineration yield carbonates of potash, and of lime, manganese and iron.

2. *Analysis of the envelope of the nucleus*

(*pericarp*).—The following substances were found by the same chemists in the covering of the nucleus.

1. Menispermine.
2. Paramenispermine.
3. Yellow alkaline matter.
4. Hypopicrotoxic acid.
5. Wax.
6. Starch.
7. Chlorophylle.
8. Resinous matter.
9. Gum.

Several of the above-mentioned substances have not hitherto been detected in any other plants, and therefore will require a brief notice.

Picrotarine.—This is a white, crystalline, intensely bitter substance, soluble in 150 parts of water at 57° F., in 25 parts of boiling water, in a third of its weight of alcohol, and in less than half its weight of æther. It is insoluble in the fixed and volatile oils; but it is soluble in acetic acid. It does not combine with acids, but forms combinations with alkalis. It seems, therefore, to be an acid, though a feeble one. It is composed of—

Carbon.....	60.96, or 12 atoms =	72.00
Hydrogen ..	5.80, or 7 atoms =	7.00
Oxygen	33.24, or 5 atoms =	40.00
		<hr/>
		100.00 119.00

The poisonous effects of the nucleus depend on the picrotoxicine.

Menispermine.—This is an opaque, white, crystalline substance, soluble in alcohol and æther, but insoluble in water. It fuses at 248° F., and at a higher temperature is decomposed, leaving an abundant charcoal. It dissolves in, and saturates acids; and from these solutions alkalis precipitate it. Concentrated sulphuric acid has little action on it: hot nitric acid converts it into a yellow resinous substance, and oxalic acid. It is composed, according to Gay-Lussac, of—

Carbon	71.80, or 18 atoms =	108
Hydrogen	8.01, or 12 atoms =	12
Nitrogen	9.57, or 1 atom =	14
Oxygen	10.53, or 2 atoms =	16
		<hr/>
		99.91 150

It does not appear to have any marked action on the animal economy.

Paramenispermine.—This is a crystalline solid, insoluble in water, scarcely soluble in æther, but dissolving readily in alcohol. It is volatile, and may be sublimed unchanged. It does not saturate acids, and, therefore, differs in this respect from the preceding substance. Notwithstanding this, however, its composition is the same: hence menispermine and paramenispermine are isomeric substances.

Hypopicrotoxic acid.—This acid is an amorphous solid, insoluble in water (cold or boiling), insoluble in æther, soluble in alkalis, and precipitable from its solution in them by the mineral acids. It is composed of—

Carbon.....	64.14
Hydrogen	6.09
Oxygen	29.17
	<hr/>
	99.40

This composition differs but little from that of picrotoxicine.

Physiological effects.—(a.) *On vegetables*. A solution of the aqueous extract of *Cocculus indicus* killed a haricot plant in twenty-four hours.

(b.) *On animals generally*. It is poisonous to all animals: at least it has been found to be poisonous to dogs, goats, cows, crocodiles, birds, and insects. Goupil considered it to be a local irritant; but the correctness of this opinion is denied by Orfila. When introduced into the stomach, its irritant effects were confined to the production of nausea and vomiting. It acts on the cerebro-spinal system, causing staggering, trembling, tetanic convulsions, and insensibility. Goupil states, all fish who eat it die,—roach being killed very easily, barbel with more difficulty. "The barbel," we are told, "is, of all fish, that whose flesh the most frequently occasions accidents in those animals who eat it, probably because these fish, taking a longer time to die, the poison is longer subjected to the action of the digestive juices, and a considerable quantity of it is consequently absorbed." Orfila says *Cocculus indicus* acts like camphor on the nervous system, and principally on the brain.

(c.) *On man*. Its effects on man have not been accurately ascertained. Hill says three or four grains of it have brought on nausea and faintings. It is frequently added to malt liquors, for the purpose of increasing their intoxicating powers; but from some accounts which I have received, from an Excise officer, of the effects of beer thus adulterated, the action appeared to be rather on the voluntary muscles than on the intellectual powers.

The operation of *Picrotarine* is analogous to, though stronger than, that of *Cocculus indicus*. Ten or twelve grains, given by the mouth, are sufficient to kill a dog. A grain and a half, injected into the jugular vein of a dog, killed the animal in twenty minutes.

Uses.—*Cocculus indicus* is rarely employed in medicine. It has, however, been used as an external application, in the form of powder or ointment, to destroy parasitic animals, (hence the Germans call these berries *Läusekörner*—that is, *Louse*

grains), and in some skin diseases, as porrigo.

Notwithstanding the severe prohibitory statutes against the employment of *Cocculus indicus* in brewing, the officer just alluded to, assures me he has frequently discovered this poison in beer, and has fined the parties for using it. It is, however, now commonly employed in the form of powder or solution, and is not so readily recognized. He also referred me to Morrice's "*Treatise on Brewing*," which has passed through many editions (a proof of its extensive sale), and in which are given full directions for the employment of this drug. In the manufacture of porter, this author directs 3lbs. of *Cocculus indicus* to be added to every 10 quarters of malt. "It gives," says this rascal, "an inebriating quality, which passes for strength of liquor;" and he also says it prevents "second fermentation in bottled beer, and consequently the bursting of the bottles in warm climates."

Administration.—The ointment of *Cocculus indicus* is prepared with one part of the powdered berries to two parts lard. Jäger has employed in the same cases an ointment composed of ten grains of picrotoxin to an ounce of lard.

Antidote.—In a case of poisoning by either *Cocculus indicus* or picrotoxin, the first object is to expel the poison from the stomach; and for this purpose we should administer emetics.

No antidote is known, though acetic acid appeared to Boullay to diminish the effect of picrotoxin.

Cissampelos Pareira.

History.—The root of this plant was first mentioned by Piso, in 1658, under the name of Caapéba. It was introduced into Paris in 1688 by M. Amelot, the French ambassador at Portugal.

It is usually termed *Pareira* (Parreyra) *brava*, which means literally *wild* or *bastard vine*, on account of its supposed resemblance to the root of the wild vine. The Germans call it *Grieswurzel* (i. e. gravel root), on account of its beneficial effects in stone or gravel.

Botanical history.—*Cissampelos Pareira* is a climbing shrub, a native of South America,—particularly of Jamaica, Martinique, St. Domingo, &c. The root is woody and branching,—the stem round and smooth,—the leaves peltate, subcordate, ovate-orbiculate, on the under surface silky-pubescent (on which account, says Dr. Wright, the plant is called *velvet leaf*.) The flowers are small, yellow, and dioecious: the fruit is reniform, hairy, and red. In the Linnean arrangement, *Cissampelos* belongs to class *Diacia*, order *Monadelphus*.

Physical characters.—The officinal part or root occurs in more or less cylindrical pieces, sometimes flattened or bluntly angular. Some of the pieces are as thick as a child's arm,—their length often a foot or more long. Externally they are covered with a dark brown rind or cortex, which is furrowed longitudinally, and wrinkled transversely. The wrinkles have very much the appearance of large, transversely elongated lenticellæ. The surface of the transverse section of the root is of a yellowish-grey colour, and presents a number of concentric circles (the annular layers), traversed by numerous radiating lines (medullary rays); between these lines are triangular bundles of woody fibres and ducts,—the latter are large, and being cut transversely, constitute the numerous holes or apertures presented by the cut surface.

The number of concentric circles varies with the age of the root. The fracture of the root is coarsely fibrous. The taste is sweetish—aromatic, afterwards bitter and unpleasant. The root is without odour.

Substitution.—Kunze, in his "*Pharmaceutische Waarenkunde*," remarks, that "on the whole, the Pareira has more the condition of a stem than of a root." In the MEDICAL GAZETTE for September 24, 1836, we are told, on the authority of a highly respectable drug firm, that a spurious article (probably the stem of the Pareira) had been imported. In consequence of this notice, I have procured a sample of it: it is certainly a stem, since it has a distinct medulla; while the cortex is partially covered with a yellowish-white crustaceous lichen. Its age must be about seven years, since it has seven annual layers: it presents the same circles, rays, and duct apertures, observed in the genuine pareira root. The diameter of the stem is nearly three inches. Doubtless its effects are similar to those of the root, though from the larger quantity of ligneous tissue, it must contain a great deal of inert matter. "It yields," we are told, "only a very minute quantity of the extract; and the decoction prepared from it, according to the usual formula, has only a slightly bitter taste, instead of the strong bitter of the decoctions of the root."

Chemical composition.—The only analysis of this root with which I am acquainted, is that of Fenuelle, made some years since. According to this chemist, the constituents are—

1. A soft resin.
2. A yellow bitter principle, analogous to cathartin; soluble in alcohol and water, and precipitable by tincture of galls or subacetate of lead.
3. A brown colouring matter.
4. Vegeto-animal matter.

5. Fecula.
6. Super malate of lime.
7. Nitrate of potassa.
8. Ammoniacal and mineral salts.

The presence of starch, or fecula, in this root, is shown by the action of iodine on it. The infusion is precipitated by the infusion of galls, and is made brown by the chloride of iron.

The active principle of the root is said to be the yellow bitter principle above mentioned: but the presence of nitrate of potash may contribute to the diuretic effect. In all probability the yellow bitter matter is a mixture or compound of various principles.

Physiological effects.—I am acquainted with no experiments made to determine the effects of this root in the healthy state of the body. From its taste, botanical affinities, and effects in diseases, we may infer it to possess a tonic operation. Occasionally it acts as a diuretic. It has been supposed to exercise a specific influence over the mucous membrane lining the urinary passages. In large doses it is said to be aperient.

Uses.—It was originally introduced into medicine as a lithontriptic. Its powers in this way were at one time highly vaunted, and Helvetius even went so far as to assert that calculi the size of an olive had disappeared under its use, and that the operation for lithotomy was no longer necessary! We now employ it in the following cases:—

1. *As a tonic in dyspepsia*, where there are no symptoms of gastric irritation.

2. *In discharges from the urino-genital mucous membrane.*—It has been employed in gonorrhœa, leucorrhœa, and chronic inflammation of the bladder. In the latter of these diseases, Sir B. Brodie says he has seen more good done by this root than by the uva ursi. "I am satisfied," says this eminent surgeon, "that it has a great influence over the disease which is now under consideration, lessening very materially the secretion of the ropy mucus, which is itself a very great evil, and, I believe, diminishing the inflammation and irritability of the bladder also."

Mode of administration.—This root may be given in the form of powder, in doses of half a drachm or a drachm. The infusion of the Pharmacopœia is prepared by digesting six drachms of the root in a pint (twenty ounces) of boiling water. The dose of this preparation is one or two fluid ounces. Sir B. Brodie recommends a decoction of the root, which he directs to be thus prepared:—"Take half an ounce of the root of the pareira brava; add three pints of water; let it simmer gently near the fire until reduced to one pint. The patient may add to it some of the tincture

of hyoscyamus; and in those cases in which there is a deposit of the triple phosphates, you may also add some of the muriatic or diluted nitric acid." The extract, which is now an officinal preparation, may be used either alone or in conjunction with the infusion. A tincture, or essence, as it is sometimes called, has been prepared by digesting one part of the root in five parts of rectified spirit. It is reputed diuretic and anticatarrhal, and has been given in doses of a fluidrachm.

AURANTIACEÆ.

Two genera of this family require to be noticed—namely, *Feronia* and *Citrus*.

Feronia Elephantum.

This is a large tree, found in most parts of India. It belongs to class *Decandria*, order *Monogynia*, in the Linnæan arrangement. From the stem there exudes a gum, which, according to Dr. Ainslie, is used for medicinal purposes by all the practitioners of Lower India, and very closely resembles the gum of the *Acacia*, commonly known in this country by the name of Gum Arabic.

It is not improbable, therefore, that part of the gum brought to us from India, and which is known in this country by the name of *East Indian Gum Arabic*, may be the produce of this tree. Further information on this point is, however, required. When I describe the *Acacia* gum, I shall notice that brought from India.

Citrus.

Under this generic name is included a considerable number of plants. Botanists, however, are not quite agreed as to which of these form distinct species, and which merely varieties.

Characters of the genus.—The plants are trees, or shrubs, with simple, alternate, petiolated leaves. The calyx is pitcher-shaped, and from three to five cleft; the corolla consists of from five to eight petals; the stamina are numerous (from twenty to sixty), their filaments being combined into several fasciculi, and their anthers being oblong; the style is round, the stigma is hemispherical. The fruit is baccate, with from seven to twelve many seeded, pulpy cells. The rind of the fruit is considered by Decandolle to be analogous to a torus, but by Mr. Lindley is, perhaps more correctly, regarded as the union of the epicarp and sarcocarp, analogous to that of the drupe: the external yellow portion of the rind is termed *flavedo*, and, by the French, *zeste*; in it are found the vesicular, or rounded receptacles (formed by the dilatation of the intercellular passages), which contain an essential oil. The internal portion of the rind is white and spongy; the cells of

the fruit are filled with little pulpy bags, which contain an acid juice, and may be readily separated from each other. The seeds are exalbuminous, and usually show very distinctly the raphe and chalaza. Thus, on the external surface of an orange or lemon seed, the markings of the raphe are very evident, and when the external coat of the seed is removed, the place of the chalaza is indicated at one end of the seed by the dark-coloured spot on the inner coat.

In the Linnean arrangement, the plants of this genus belong to class *Polyadelphia*, order *Polyandria*. The official species are four in number—namely,

1. *Citrus Limetta*; var. *Bergamium*.
2. *Citrus Limonum*.
3. *Citrus Aurantium*.
4. *Citrus vulgaris*.

But to render the account more perfect, we may notice another species—namely, *Citrus medica*. I shall speak of them in the order they are described in Decandolle's *Prodromus*.

1. *Citrus medica*.—The fruit of this species is denominated the *citron*. It is supposed to be the *μηλέα μηδική* of Theophrastus, and the *malus Assyria vel medica* of Pliny. Risso has noticed three varieties of it.

The following are the distinguishing characters of the species:—The petioles are naked; the leaves are oblong, acute, and very finely dentate; the flowers have forty stamens; the fruit is oblong, rugous, with a thick rind, and a slightly acid juice.

FIG. 156.—*Citrus medica*; the Citron.

Those fruits which preserve their pistilla are called *pitmas*: they are sought after, says Risso, by the Jews, who suspend them to palms at the feast of the tabernacle.

The leaves are interposed between linen, to which they communicate a fragrant

odour: moreover, they are said to keep away insects.

By distillation, there is obtained from the rind of the fruit a fragrant oil (*oleum essentielle citri*), lighter than that procured from the lemon: it is employed by perfumers.

There is another oil met with in commerce, under the name of the *essential oil of cedar*, and in most books it is erroneously stated to be identical with the oil of citron. It has the combined odour of the citron and bergamot. It is employed by perfumers. It has the same elementary composition as the essential oil of lemons, presently to be mentioned.

2. *Citrus Limetta*.

This species is characterized by naked petioles; ovate, roundish, serrated leaves; flowers with thirty stamens; the fruit (commonly termed the *lime*) is globose, with a firm cortex and sweet pulp.

FIG. 157.—*Citrus Limetta*; the Lime.

Risso mentions seven varieties: one of these is the *Bergamium*, from the flavedo of the fruit of which is obtained an essential oil—the *essence* or *oil of bergamot* of the shops—called in the Pharmacopœia the *oleum bergamii*. This oil has a pale yellow colour, a remarkable odour, and a specific gravity of 0.885. Its elementary composition is similar to that of the essential oil of lemons. It is used in medicine only on account of its odour.

3. *Citrus Limonum*.

This species is characterized by its petioles being somewhat winged. Its leaves are oblong, acute, and dentate; its flowers have thirty-five stamens, but are often without pistilla; the fruit (called the *lemon*) is oblong, has a very thin rind, and a very acid juice.

Risso includes no less than twenty-five varieties in this species.

FIG. 158.—*Citrus Limonum*; the Lemon.

We employ in medicine the rind, the essential oil obtained from the rind, and the juice. From the latter is procured citric acid.

1. *Essential oil of lemons*.—This is the *oleum limonis* of the London Pharmacopœia. It is prepared as follows: the lemons are rasped to remove the flavedo, which is afterwards expressed in hair sacks. The oil which is thus procured is received in flasks, where it is allowed to deposit; it is then decanted and filtered. As thus procured the oil is very fragrant, but somewhat turbid, and liable to undergo change from the mucilage present. It may be obtained also by distillation, and the oil is then more permanent, but its flavour is less pleasant and sweet; and hence this process is rarely practised. The greater part of the oil of commerce is brought from Portugal and Italy; some, however, is procured from France.

When quite pure it is colourless, limpid, and of a fragrant odour, like that of lemons. Its specific gravity at 70° F. is 0.847. It is soluble in all proportions in anhydrous alcohol; it boils at about 345° F. When the commercial oil is exposed to a temperature of 4° F., it deposits white crystals, whose nature is not known; but rectified oil does not thus deposit.

This oil is composed of two other isomeric oils; one (called by Dumas *Citrene*; by Blanchet and Sell *Citronyle*) capable of forming a crystalline compound with muriatic acid; the other oil (called *Citryle*) does not form a crystalline compound with this acid.

According to the analysis of Dumas, the oil of lemons is composed of—

10 atoms carbon	60
8 atoms hydrogen	8
	—
	68

This composition is analogous to that of the oil of turpentine, but the condensation is one half less. The oils of cedar, bergamot, and probably of orange, have a similar composition.

When hydrochloric acid gas is passed through this oil, a crystalline compound is formed, which has been termed *artificial camphor of the essence of lemon*, or *hydromerite of citrene*. It is composed of—

10 atoms carbon	60
9 atoms hydrogen	9
1 atom chlorine	36
	—
	105

Or, we may consider it as composed of—

1 atom citrene	68
1 atom hydrochloric acid	37
	—
	105

This oil is employed as a perfume, as a flavouring ingredient, and, when distilled, it constitutes the *scouring drops* of the shops, used for removing grease spots from silks, and other textures. It is regarded as diaphoretic.

2. *Lemon peel*,—the *cortex limonum* of the Pharmacopœia. The flavedo of this cortex is of a pale yellow colour, rough from the presence of the oil receptacles, of a strong peculiar odour, and an aromatic bitter taste. The internal portion of the cortex is white, spongy, and almost without odour or taste. The watery infusion of lemon peel becomes of a greenish brown colour, on the addition of the chloride of iron. If water be distilled from this freely, we obtain the *water of lemon peel* of the Edinburgh Pharmacopœia, which, however, is rarely used in medicine. Lemon peel may be regarded as a stomachic and aromatic substance. It is employed more as a flavouring ingredient than for its proper medicinal effects. It is one of the ingredients of the *compound infusion of orange peel*, and of the *compound infusion of gentian*.

3. *Lemon juice*: *succus limonum*.—Lemon juice is composed, according to Proust, of—

Citric acid	1.77
Malic acid, gum, and bitter extractive	0.72
Water	97.51
	—
	100.00

On account of the presence of mucilage and extractive, it is very apt to undergo decomposition, though various methods have been resorted to for the purpose of preserving it. As a substitute for lemon juice, we may employ the following:—

Water, 16 fluid ounces,

Citric acid, 8½ drachms,

Oil of lemon, a sufficient quantity, to give it the proper flavour.

Lemon juice owes its medicinal properties to the citric acid contained in it: it is refrigerant, and when properly diluted, and slightly sweetened, is a most agreeable and refreshing beverage.

The only official preparation of this juice is the *syrup of lemons* of the Pharmacopœia.

1st. *In the preparation of refrigerant drinks.*—Thus it is added to barley-water, or it is mixed with sugar and water, to form the beverage called *lemonade* (the *hydrolé de citrons* of the French pharmacologists). The proportions of the ingredients for making this latter compound are two lemons sliced, two ounces of sugar, and two pints of boiling water: digest until cold. These drinks are most refreshing and grateful in febrile and inflammatory diseases, in hæmorrhages, &c.

2. *In the formation of the effervescing draught.*—A table-spoonful, or four fluid drachms, of lemon-juice, are about equal to seventeen grains of crystallized citric or tartaric acid. The effervescing draught made with lemon-juice, or citric acid and bicarbonate of potash, is one of the best remedies we possess for allaying irritability of the stomach.

3. *As an antiscorbutic*, lemon-juice has long been regarded as invaluable. On account, however, of the difficulty of preserving it, the crystallized citric acid and oil of lemons are usually substituted. Sir Gilbert Blane says, “those only who have made themselves acquainted with the early part of the naval history of this country, or those who have perused the interesting, popular, and eloquent narrative of Commodore Anson’s voyage, can duly appreciate the value of this simple remedy” (lemon-juice).

4. *As an antidote to poisons.*—In cases of poisoning by alkalies, the vegetable acids are the antidotes, and the most convenient and easily procurable acidulous substances are commonly vinegar and lemon-juice. In poisoning by narcotic substances, as opium, after the poison has been evacuated from the stomach, lemon-juice may be given to counteract the effects.

Citric acid: History.—This acid was first procured in the solid state by Scheele, in 1781. Mixed with little or no malic acid, it is found in the fruit of the Lemon, Orange, Citron, Dulcamara, Dog Rose, Bird Cherry, red Whortleberry, and Cranberry. Mixed with about an equal quantity of malic acid, it is found in the Gooseberry, red Currant, Bilberry, Pyrus Aria, Cherry, Strawberry, Raspberry, and Cloudberry. According to Vauquelin it exists in the Tamarind, mixed with malic and tartaric acids. Citrate of potash is

found in *Aconitum Lycoctonum*, in the fruit of the Gooseberry and Capsicum, in the root of *Asarum europæum*, and the tubers of *Helianthus tuberosus*. Citrate of lime is met with in *Asarum europæum* (*Salanum tuberosum*) and also in the bulbs of Garlic, and the herbaceous part of *Isatis tinctoria*.

Preparation.—It is obtained from lime or lemon juice, the latter of which is imported for the purpose in pipes and hogsheads. This juice, placed in a large vat, is saturated with chalk or whiting. The supernatant liquor is then drawn off, the precipitate (citrate of lime) passed through a sieve, and frequently washed with warm water, until the mucilage and other soluble impurities be entirely washed off. The citrate of lime is then decomposed by sulphuric acid diluted with water; sulphate of lime separates, and citric acid remains in solution. The clear solution is then to be evaporated (manufacturers use for this purpose leaden boilers), and the concentrated solution set aside to crystallize. To purify the acid the crystals are to be re-dissolved, and the solution again put by to crystallize; this process is to be repeated until the crystals have the requisite degree of whiteness.

Properties.—Anhydrous citric acid is white and odourless, and strongly reddens litmus. It consists of—

4 atoms carbon	24
2 atoms hydrogen	2
4 atoms oxygen	32
	<hr/>
	58

The primary form of crystallized citric acid is the right rhombic prism. Those crystals which are procured by the cooling of a hot solution of the acid consist of—

1 atom anhydrous citric acid	58
1 atom water	9
	<hr/>
	67

Berzelius says that the crystals of commerce, formed by spontaneous evaporation, usually contain one-third of an atom of water more than is here stated.

The crystals absorb moisture from a damp atmosphere; and Dumas, therefore, is in error when he says they are unalterable in the air. When they are distilled in a retort, they yield among other products an acid liquor, from which has been procured a peculiar substance called *pyro-citric acid*.

Characteristics.—A solution of citric acid does not produce any precipitate with lime water: hence it may be readily distinguished from a solution of oxalic acid. From tartaric acid it may be distinguished by its not forming a crystalline precipitate when an excess of it is added to a solution of carbonate of potash. It forms

with barytic water a white precipitate (citrate of barytes), soluble in excess of acid. With a solution of acetate of lead it also causes a white precipitate (the citrate of lead.)

Adulteration. — Not unfrequently citric acid is adulterated with tartaric acid; this is especially the case when it is sold in a pulverent form. The fraud may be easily discovered: dissolve the suspected acid in water, and to the solution thus ob-

tained add cautiously a solution of carbonate of potash, taking care that the acid be in excess. If any tartaric acid be present, a white crystalline precipitate (bitartrate of potash) is formed.

Saturating power. — As this acid is frequently employed in the making of effervescing mixtures, it may not be useless to mention the quantities of the alkaline carbonates necessary to saturate it.

20 grains of	{	Sesquicarbonate of ammonia will saturate	}	24 grains citric acid.
		Carbonate of potash		17 ditto.
		Bicarbonate of potash		14 ditto.
		Carbonate of soda ..		nearly 10 ditto.
		Sesquicarbonate of soda, rather more		16½ ditto.

Physiological effects: (a.) *On vegetables* — I am not acquainted with any experiments made with citric acid on vegetables; but its effects are doubtless analogous to those of tartaric acid, to be noticed hereafter.

(b.) *On animals generally.* — Orfila ranks citric acid among the irritant poisons; but Drs. Christison and Coindet gave drachm doses to cats, without observing that the animals suffered any inconvenience.

(c.) *On man.* — We are not acquainted with the effects of large quantities of this acid on man. Dissolved in water, and taken in moderate doses, its effects are analogous to those of the dilute mineral acids before mentioned; that is, it allays thirst, diminishes preternatural heat, checks profuse sweating, and promotes the secretion of urine. Vogt says it acts more on the skin than tartaric acid (in this respect being similar to acetic acid), and less on the alimentary canal and urinary organs. Continued use gives rise to disorders of the digestive organs.

Uses. — The uses of citric acid are the same as those of lemon juice already mentioned, and for which it is employed as a substitute. A solution of citric acid has also been used as a solvent for opium, by Dr. Porter, of Bristol.

4. *Citrus Aurantium.*

The essential characters of this species are, petioles nearly naked; leaves ovato-oblong and acute; flowers containing twenty stamina; fruit (the common sweet orange) globose, with a thin cortex and sweet pulp.

Risso enumerates no less than nineteen varieties.

The leaves of the orange-tree are feebly bitter, and contain a volatile oil. They have been used in the form of powder, or infusion, in spasmodic diseases. Distilled with water, they yield a very fragrant oil, called the *essence de petit grain*. Formerly, the oil sold under this name was procured

FIG. 159.—*Citrus Aurantium*; the Orange.

from unripe oranges, but, as thus obtained, it is very subject to decompose.

Orange flowers (*flores aurantii*) are now officinal articles. According to Boullay they contain ætherial oil, yellow, bitter, extractive, gum, acetic acid, and acetate of lime. They yield, by distillation, a very fragrant oil, called, by perfumers, the oil of Neroli, but which is termed, in the Pharmacopœia, *oleum aurantii*. The essence de petit grain, being much cheaper, is frequently substituted for it. The oil of Neroli is used in medicine, on account of its flavour.

The small green fruits of the orange-tree, which fall during the great heats of the summer, are carefully collected and dried. They form the orange berries, the *baccæ aurantii* of the old Pharmacopœia. Their size does not exceed that of a cherry; their colour is dark greyish or greenish brown; they have an aromatic odour and bitter taste. When smoothed by a lathe, they constitute the *issus peas* of the shops: they are preferred to ordinary peas for keeping up the discharge of an issue, on account of their pleasant odour. An infusion of orange berries is rendered green by the chloride of iron:

CLINICAL LECTURES,

DELIVERED AT THE

MEATH HOSPITAL AND COUNTY
OF DUBLIN INFIRMARY,

During the Session 1836-7.

BY PROFESSOR GRAVES.

LECTURE VII.

Scarlatina without eruption, followed notwith-
standing by desquamation—Thoughts on
the nature of desquamation—Latent Scarla-
tina, followed by Anasarca—General pro-
position respecting the symptoms of animal
poisons—Morbid appearances after delirium
in fever—Treatment in anticipation of cere-
bral symptoms—Great advantage of blisters
judiciously employed—Notice of the old mode
of blistering.

BROOK I resume the thread of my dis-
course, permit me to mention some curious
facts recently observed. Dr. Marsh and I
attended, not long since, a lady who had
been affected for some days with fever and
sore throat. She had no eruption on any
part of her body, but from the character of
the fever, and the peculiar appearance of
the throat, we suspected she was labouring
under an attack of scarlatina. Her family
were very anxious to ascertain the precise
nature of her complaint; and I visited
her twice a day for the first four or five
days of her illness, carefully examining
the skin at each visit, but could not dis-
cover the slightest trace of an efflorescence
of any description. She continued for se-
veral days to suffer from the fever and sore
throat, and was at one time in a dangerous
condition, but ultimately recovered by
great care and the use of appropriate re-
medies. Now I watched this case from
the sixth hour after its commencement to
its termination, and repeatedly examined
the skin, particularly that of the breast,
abdomen, and inside of the knee and
elbow joints, places in which the eruption
shews itself when it appears at all, but
could not discover any vestige of it. You
will often find a diffused redness about
the knees and elbows, in cases where the
eruption does not appear on any other
part of the body; but in this instance
there was not the slightest deviation from
the natural hue. Yet the result proved
that it was scarlatina; for the desquama-
tion of the cuticle, which always attends
this disease, took place, and the lady com-

municated the infection to several members of the family. A young gentleman residing in the house got a bad attack of scarlatina, two of the servants were also attacked, and the lady's father got sore throat; in fact, there could be no doubt as to the nature of the disease. During her convalescence she had desquamation of the cuticle; and this is a point to which I would particularly call your attention. We are taught to look upon desquamation as the result of cutaneous affections of an inflammatory character; and it is an opinion very generally maintained, that in scarlatina, as in psoriasis, the peeling off of the cuticle depends on a peculiar state of the skin produced by inflammation. It is stated that the increased vascularity of the skin occasions a morbid secretion, and subsequent detachment, of the epidermis, and that the same phenomenon is observed in all cutaneous affections of an inflammatory character. This may be generally, but not universally, true; for here we had an extensive desquamation of the cuticle without any eruption, without any previous redness, pain, or remarkable heat; in fact, without any of the phenomena which are regarded as constituting inflammation. This seems to prove that there is something more than inflammation concerned, as preparatory to that process which is termed desquamation, and that the change which the skin undergoes is not to be looked upon as a mere consequence of inflammation occupying the external surface of the corium.

Another curious fact observed in this lady's case: since the attack which I have just described she has been shedding her nails; that is to say, the nails of the fingers are all dropping off, and yet there is no appearance of inflammation of any kind about the hands to explain the occurrence. You are, of course, all aware that the dropping off of the nails is a species of desquamation. From the peculiar structure of the nail, and the mode in which it is formed in the matrix, it does not drop off at once like a scale of epidermis; still I think we are authorized in looking upon the shedding of the nails as a species of desquamation. This affords a very curious subject for investigation, as connected with the history of fever. It is an opinion entertained by many persons, that desquamation of the skin takes place at a particular period of typhus, and that this is not an occasional, or varying, but a constant and general, phenomenon. This statement has been put forward most strongly by Dr. Perry, of Glasgow; and he is also of opinion, that the period in which typhus is most contagious, is during the desquamation of the cuticle. It is also asserted, that scarlatina is more contagious during desquamation than at any

other period of the disease. This is at least the popular idea; how true it may be my experience or observation does not enable me to decide; nor am I prepared to offer any thing like an explanation of the occurrence. All I shall say on the present occasion is, that the occurrence of desquamation of the cuticle in typhus, and in cases of scarlatina without eruption, has greatly altered my ideas as to the connexion between it and cutaneous inflammation. I think, at least, that the process of desquamation in such cases is very different from inflammation, and that the morbid action of which desquamation is the result, has very little in common with the ordinary process of inflammation of the cutaneous surface.

A gentleman who is in the habit of attending my lectures informs me that he has seen three cases of this form of scarlatina, characterized by the absence of the external efflorescence. They occurred in young persons, after puberty, and between the ages of 15 and 25. Each of these cases exhibited a considerable degree of fever, with increased quickness of pulse, thirst, heat of skin, diminution of the urinary secretion, and, after the first or second day, much depression, which continued for two or three days, and then yielded to treatment. The tongue was moist, but pointed, tremulous, red, and injected. The velum, isthmus faucium, tonsils, and upper part of the pharynx, were somewhat swollen, and of a very peculiar dark-red colour, the redness being general, and equally diffused over the whole of the upper part of the pharynx as far as it could be examined. But the following case, which was very lately communicated to me by a practitioner of very great eminence in this city, is still more curious. Some years ago scarlatina broke out in this gentleman's family, and attacked all his children with the exception of one young lady, who, although in constant attendance on her sisters during their illness, did not exhibit any symptoms whatsoever of the disease. When all the children had become convalescent, they were removed to the country for the benefit of air, whither she also accompanied them. Here she was, much to the astonishment of her family, attacked by the peculiar anasarca observed in persons who have recently laboured under scarlatina. Her father, under whose observation she had been during the whole time, was very much struck with the occurrence; he paid particular attention to the case, and feels convinced that it was the result of latent scarlatina. This case, connected with those already detailed, are of great interest in a general pathological point of view. They appear to prove the fact, that in some instances diseases produced by contagion do not give rise to the

whole train of phenomena by which they are ordinarily characterized.

Let us turn for a moment to some of those diseases caused by the action of animal poisons on the system, as for instance measles. The symptoms which generally attend and characterize measles are universally known. After an attack of fever, on the third or fourth day, coryza, sneezing, hoarseness, and cough, are complained of, and then a rash appears, first on the face, and afterwards on the body and limbs. But it is not necessary that all these symptoms should appear, and that the sequence of morbid phenomena should be uninterrupted throughout; on the contrary, it frequently happens at particular periods, and in certain constitutions, that some of the most usual symptoms are scarcely observed, or altogether absent. You will find this point insisted on by Dr. Bateman, who has given a detailed description of a form of measles in which the catarrhal symptoms are wanting, and which he has termed *Rubeola sine catarrho*. The same remark applies to many other forms of disease. Thus we may have pneumonia without cough, and pleuritis without pain in the side. Those who have witnessed the course of the late epidemic cholera in this country, will recollect that many cases occurred in which vomiting, purging, or cramps, were not observed.

If we turn to fever, we find that the animal poison to which it owes its origin generally exhibits a certain number of symptoms, congregated together, or observing a determined order and succession; and these we meet with in most of the cases which come before us in practice. But we now and then see fever patients in whom one or more of the most prominent symptoms are absent. Thus occasionally there is no quickness of pulse or appearance of vascular excitement; in some there are no cerebral symptoms; in others no increase in the temperature of the skin. Indeed, I might go through the whole group of symptoms which accompany fever, and show that almost every one of them may be occasionally absent, and yet the fever of a severe and dangerous type. I recollect pointing out to the class last year the case of a man labouring under chronic enlargement of the spleen. He had been working for two or three seasons in some of the marshy districts of England, and had been occasionally ill, but never had symptoms of regular intermittent; in fact, he had escaped the intermittent itself, but not what are usually deemed the consequences of it. We have been in the habit of explaining the enlargement of the spleen by referring it to the conflux of blood towards the internal organs, particularly the

liver and spleen, during the cold stage of intermittent; and we have endeavoured to explain the subcutaneous œdema which follows scarlatina, by attributing it to previous inflammation of the skin and subcutaneous cellular tissue; but the observations and facts which I have now brought forward will show that these opinions were founded on erroneous ideas. Turning to cases of chronic disease, we find in some, as for instance syphilis, that the poison taken into the system gives rise in most cases to a determinate order of symptoms, *e. g.* bubo, sore throat, eruptions on the skin, nodes, and syphilitic cachexy. Mr. Hunter has been at great pains in determining the order of the parts, and pointing out the tissues which are successively affected, and it is of considerable importance to have correct notions on this point; but although the number and order of symptoms marked out by Mr. Hunter and others may be observed in most cases, they are not so in all; and the same remark which has been made on the occasional absence of one or more important symptoms in scarlatina will apply with equal force to syphilis. Now and then the morbid poison which excites syphilis does not affect the constitution in such a manner as to occasion the production of all the symptoms which usually characterize this disease, and thus a variety of venereal is formed, which often proves a source of great embarrassment not only to the young and inexperienced, but even to the senior members of the profession.

It is of great consequence, in a practical point of view, to bear in mind the general proposition I have announced, *viz.* that in both acute and chronic diseases *a constitutional affection may display its existence by only one or two of the numerous symptoms which usually accompany it*; and this occurrence seems more frequent in the case of diseases produced by contagion and morbid animal or vegetable poisons, than in the case of maladies generated by causes developed in the system itself.

I spoke at my last lecture of a man named Cassels, who died in the fever ward with symptoms of cerebral excitement, and stated that I regretted having omitted to leech his head, and prescribe tartar emetic in the form of enema. Since that time we have had an opportunity of examining his body, and the results of the dissection are well worthy your attentive consideration. He was a young man of a robust habit and apparently good constitution, and laboured under the ordinary form of maculated typhus. Shortly after his admission he was attacked with delirium, which was soon afterwards followed by coma and death. Now, suppose you were called to see a patient, not labouring under typhus, but exhibiting a

similar train of symptoms,—that is to say, violent delirium, accompanied by flushing of the face, suffusion of the eyes, headache, and a tendency to get out of bed—in fact, a state of furious excitement requiring the restraint of the strait waistcoat,—what idea would you be likely to form of the condition of the brain? If a patient of this kind had no typhoid symptoms, you would certainly say that he was labouring under meningitis or cerebritis; and if the case proved fatal, you would naturally expect to find lesions of the brain fully sufficient to account for all his symptoms. And you would in all probability find extensive thickening of the membranes of the brain, with subarachnoid effusion, or you would discover softening, increased vascularity, and suppuration of the encephalic mass. But, here, a man in fever exhibits all the symptoms of cerebral inflammation; the cerebral affection runs on to a fatal termination with great rapidity; he dies comatose. And what do we find on dissection? Doubtful signs of congestion, and no distinct evidence of inflammation; a slight opacity of the arachnoid at the base of the brain, and about a tea spoonful of clear subarachnoid effusion. Now this is a point to which I would earnestly call the attention of every inquiring student. A patient, during the course of typhus, is seized with symptoms which are generally regarded as characteristic of congestion and inflammation of the brain; he dies to all appearance in consequence of the intensity and violence of these symptoms, and on dissection little or no trace of cerebral disease is found. In the case under consideration, the symptoms present were strongly indicative of congestion if not of inflammation; and had the man been free from typhoid symptoms, you would expect to find decided traces of inflammatory mischief. This seems to prove that in the production of cerebral symptoms in typhus, some cause not to be recognized by the production of cerebral lesions, or in other words, something besides mere congestion or inflammation, exists. I have now examined a great number of cases of this description, and the examination has brought home to me a strong conviction, that the delirium of fever depends upon something more than mere inflammation or congestion. There is another fact, the study of which is well worthy of attention, as it appears to support very strongly the views I have put forward; and this is the occurrence of analogous symptoms under opposite conditions of the cerebral circulation. Take, for example, the phenomena of vertigo and headache. Now, these symptoms are found in states of the brain which are directly opposite. In incipient congestion

of the brain, in that turgescence of the cerebral vessels which precedes apoplectic seizures, one of the most frequent symptoms is vertigo, and the same thing may be affirmed with respect to headache. But we observe the very same symptoms under circumstances totally dissimilar. Frequently, while bleeding a patient for some affection of the lungs or bowels, or for some accident, we find that after a certain quantity of blood has been lost, the patient becomes pale; and while the pallor is coming on, he often gets quite giddy, and sometimes complains of headache. Gentlemen who are attending lying-in hospitals are well acquainted with the headache, giddiness, and tinnitus aurium, so constantly complained of by females who have suffered from excessive uterine hæmorrhage. Hence you perceive facts are not wanting to show that opposite states of the cerebral circulation, a superabundance or deficiency of pressure on the brain, may give rise to similar phenomena. You saw an illustration of this in the case of one of our patients in the fever ward this morning. He was quite free from headache as long as he remained in the horizontal posture, but the moment he sat up in bed he complained of headache. Yet this was a man who had not the slightest symptom of determination to the head, and who had been sufficiently depleted during his illness. You will also recollect the fact, that persons who have had a long illness, and remained for many days in the horizontal posture, generally get weakness, giddiness, and sometimes headache, at first when they attempt to sit up during convalescence. This is a point which should always be borne in mind. You are consulted by one person who complains of giddiness, tinnitus aurium, and frequently-recurring headache. You examine the patient carefully, and you find all the symptoms of unequivocal determination to the head. You are applied to by another person labouring under the same symptoms; but how different is the state of the brain found to be on a careful examination. One patient is robust, of florid complexion, and with a hard bounding pulse; the other is a weak chlorotic female, who has been ailing for months, and whose pulse is so weak, that a slight degree of pressure obliterates the canal of the artery. Yet the tinnitus aurium, giddiness, and headache, complained of by the latter, is just as bad and as troublesome as in the case of the former.

From a consideration of these points, you will perceive that, for the production of cerebral symptoms in typhus, there must be something more than mere congestion or inflammation of the brain; but you are not to infer from this that there is

no necessity for taking any steps to obviate or remove congestion of the head in fever. On the contrary, I am of opinion that in typhus one of the principal sources of danger is connected with the head, and that the cerebral symptoms should be always watched with the most unremitting and anxious attention. It is this which constitutes the great difference between the mortality in private and hospital practice. In private practice the physician is called at an early period of the disease, and has an opportunity of checking the cerebral symptoms before they rise to a dangerous height; but hospital patients, in general, are admitted at an advanced stage of fever, and in many instances have been improperly treated, or wholly neglected from the commencement. I am also of opinion, that when there is any evidence of determination to the head, the best way of preventing dangerous cerebral symptoms is to deplete the head by the application of a sufficient number of leeches, and then to proceed to the use of blisters. You should direct your attention as much to the head as to the bowels, and one of the best modes of doing this is to apply six or eight leeches behind the ears, and repeat them every six hours until relief is obtained. You should then order the head to be shaved, and kept constantly covered with cloths wet with warm vinegar and water, and at the same time have recourse to the internal use of tartar emetic and nitre, or blue pill, with James's powder. Should this plan fail in giving relief, you have a powerful aid in the application of blisters to the scalp, and this must be done extensively, and at once.

Most of the fatal cases of typhus at present die of cerebral disease. But in the majority of instances you will find that these were cases in which the head was neglected, and in which the appropriate remedies were used too late. In cases treated from the commencement with judgment, decision, and attention, although the head may be threatened, you will not have one-twentieth of the mortality observed in those cases where the early prevention of cerebral symptoms has not been an object of care. One of the worst cases of cerebral disease which I have witnessed for many months, and which would have probably terminated fatally before the seventh day, I saw in consultation with Mr. Daly, and yet this case was saved by prompt and decided measures calculated to counteract the cerebral symptoms. I have also very recently witnessed another very remarkable case of this description at Bray.

The patient, a gentleman very full and plethoric, but remarkably temperate,

aged 35, was attacked after exposure to cold by intensely violent maculated fever, for which aperients of an active nature were exhibited. I saw him in consultation with Dr. Heffernan on the 5th day. His headache had been relieved by leeching, but his breathing was very quick, and he was almost constantly asleep. Skin very hot; eyes somewhat suffused; most copious crop of maculæ. We at once blistered the whole scalp; and on the 8th day blistered it again, and also the nape. On the 9th day the cerebral symptoms, which we had been endeavouring to anticipate, came on, but probably our treatment prevented them from being fatal; for when they appeared, the application of tartar emetic ointment induced a purulent discharge from the whole surface of the twice blistered scalp, in the course of a few hours, and three grains of tartar emetic given in divided doses that day procured a complete cessation of the symptoms, after—mark, after—the pupils had been dilated, and one fit of slight paralysis of the mouth and tongue had taken place.

The result of all my experience in fever is, that the majority of fatal cases are rendered so, in this country at least, by severe cerebral symptoms supervening sooner or later in the disease. Delirium, sleeplessness, stupor, convulsions, extreme subsultus, jactitation, sluggish and dilated, or else extremely contracted, pupils; these are the symptoms we have to fear after the fever has lasted some time; and let me repeat it, the chief art of the physician consists not so much in remedying these symptoms, as in anticipating them. When he judiciously attempts this, he may not, indeed, always succeed in altogether preventing their supervention, but he will, in the great majority of cases, be successful in diminishing their violence, and preventing their usual disastrous effects.

I shall now resume the subject of blistering in fever, on which I made some observations in my last lecture. I have spoken of it chiefly as a powerful revulsive remedy in the treatment of cerebral congestion; let us now treat of its employment with other objects in view. In the first place, as has been already explained, blisters may be used as most energetic stimulants in cases where the powers of life flag, and threaten a sudden cessation. Occasionally, in fever, you will find the vital tone reduced to a very low pitch, the heart uncertain in its action, the pulse irregular, the respiration feeble, the skin cool, and the patient so weak that he cannot be lifted up, or even turned in bed without having a tendency to faint. Here we have to superadd to the ordinary treatment of fever the prompt exhibition of remedies calculated to meet such emer-

gencies, and in addition to internal stimulants, we have recourse to powerful stimulation of the cutaneous surface by what are termed flying blisters. (One of the best remedies in such cases is a large blister applied over the region of the heart, to be left on for two or three hours, or until the vascular action of the skin is sufficiently excited. When the patient appears to labour not only under sudden weakness of the heart, but also of the capillary and nervous systems, as shown by coldness of the extremities and sinking of the pulse, it will be necessary to apply flying blisters, not only over the region of the heart, but also over various parts of the chest, the epigastrium, and the inside of the legs and thighs. You will find this plan of treatment frequently succeed in cases which have a very unpromising aspect. I have now witnessed many instances of this description, in which, from cold, neglect, or debilitating treatment, the patients appeared moribund, with lividity of the extremities, hippocratic face, cold skin, and failing pulse; and I have seen them saved, as it were miraculously, by the use of carbonate of ammonia, musk and wine, and the application of warm fomentations to the limbs, followed by a succession of flying blisters.

The next use to which we apply blisters is in the treatment of those pulmonary affections which arise during the course of typhus. From what you have seen of the present epidemic, you must be convinced that bronchitis is one of its most frequent complications, and that few patients pass through fever without having some affection of the bronchial mucous membrane. You are also aware, that when bronchitis attacks the more minute ramifications of the bronchial tubes, it is very apt to produce congestion and engorgement of the lung. We meet with pneumonia much less frequently in fever, but it is occasionally observed, and requires the most prompt and decided treatment. In pneumonia, as well as in congestion of the lungs, accompanied by inflammation of the smaller bronchial tubes, blisters afford us a most valuable adjunct to the other means which we employ, and admit of being used in cases where no other mode of depletion could be safely borne. The affections of the lung in fever are of no small importance, and the stethoscope has not conferred a greater benefit on practical medicine, than by indicating, in diseases of the chest, not merely the existence of disease, but also its locality, extent, and precise nature. It points out to us the portion of the chest in which the bronchial tubes are chiefly engaged, and informs us with certainty when the affection of the smaller tubes and air cells has given rise to pulmo-

nary engorgement. The experienced stethoscopist will in such cases be aware of the exact site and nature of the affection, where the mere symptomatic practitioner would be unable to acquire any thing more than a loose and undefined notion of pulmonary disease. The latter employs his depleting means at random, and frequently abstracts a large quantity of blood, with little benefit to his patient; the former, aware of the exact situation and extent of the disease, applies his leeches or cupping glasses immediately over the engorged or inflamed portion of the lung, and relieves his patient at the expense of a comparatively small loss of blood. The same observation will apply, with equal force, to the use and application of blisters. A good and accurate knowledge of the various stethoscopic phenomena is besides of so much more value in the treatment of fever, as, at certain seasons of the year, almost every case of fever will be complicated with pulmonary derangement; and it may happen, during the course of an epidemic, that the lungs may be the organs which are chiefly engaged. Although cerebral disease is at present the principal source of danger in fever, it may not be so always. A change may take place in the character of the epidemic; the cerebral symptoms which are now of such frequent occurrence may become infrequent or inconsequential, and we may have the organic affections chiefly limited to the viscera of the thorax. I have seen many cases of fever in which the principal source of danger was connected with the chest, and where an accurate knowledge of the stethoscope was indispensable to a correct and successful plan of treatment.

Now when you have recourse to blisters in treating pulmonary affections, whether these affections be simple or complicated with typhus, it would be well to recollect that much good may be effected without leaving the blisters on for a long time, or until they rise fully; and also that when risen, it will not be necessary to cut them at once, and let out the effused serum. In treating the bronchitis of children, and in the bronchial affections of fever, I have frequently directed the blister to be left unopened; and I can state, from experience, that this plan answers very well. The effused serum forms one of the best dressings for the excoriated surface of the skin, and the formation of troublesome sores is avoided. I frequently have recourse to this mode of treating blistered surfaces in children, and persons of irritable habit, in whom the cutis is extremely tender and vascular. Such persons, when blistered, will often have profuse discharges, first of serum and afterwards of

sero-purulent matter, from the denuded surface, accompanied by torturing pain, loss of rest, and considerable irritation of the general system. I have seen the discharge continue to flow profusely for five or six days; in fact, to such an extent as to wet several napkins in the course of a day, and expose the patient to the risk of an aggravation of the pulmonary symptoms, in consequence of his linen becoming so frequently moistened as to require repeated shifting*. In all cases of children and persons of an irritable habit, I would therefore advise you to let the blisters alone, particularly where they have been applied to the fore part of the chest, or any other part not exposed to pressure or friction. As soon as the blister rises, apply over it a piece of lint, smeared with spermaceti ointment, which can be renewed as occasion requires, and leave the rest to nature. I was forcibly struck, some time since, with the difference of result between this and the ordinary practice, in the case of a young gentleman residing in Camden-street, who had a severe attack of bronchitis towards the termination of fever. A blister had been applied to his chest in the morning, and another in the middle of the day. The first had been opened freely, and dressed in the usual way; but the other, which had risen about the time I was called in, was left untouched at my request. The one which had been opened caused such a degree of irritation and restlessness, that it was found necessary to give him an opiate every night; the other gave little or no inconvenience, and healed up much sooner. If I have done nothing better, I think I deserve some merit for being the first to reprobate the practice of keeping on blisters for twelve, eighteen, and twenty-four hours, and for having shewn, by numerous experiments, that a much shorter period of time was required to ensure the full effect of these remedies. When I commenced the practice of medicine, blistering was looked upon by most sick persons as one of the severest trials of their patience, and the agony which it caused in some irritable habits was almost insupportable. Blisters were left on for twelve, eighteen, and even twenty four hours, and when at length they were removed, the whole epidermis of the blistered part came, or was torn, away, leaving behind a raw irritable surface, from which large quantities of serum and pus were effused for several days, to the great torture and in-

convenience of the patient; and, not content with this, the practitioners of that time generally dressed the excoriated surface with some sharp stimulant ointment, so that the blistered surface most commonly resembled that of a severe burn. Ask those who are our seniors in practice, and they will tell you what blistering was twenty or thirty years ago. They first produced excessive irritation of the skin, by leaving the blisters on too long, they then irritated the denuded surface with stimulant ointments, and in this way brought on extensive sores of a bad character, which remained long after the disease for which the blisters were applied had disappeared, and which formed, in fact, a new ailment, requiring new medicines and additional attendance. If you look over Mr. Moore's account of the principal remedies employed in the practice of Dublin physicians, about the period I allude to, you will find that nothing was more common than the application of stimulant and, as they were termed, digestive ointments, to blistered surfaces. I was among the first who assailed this barbarous treatment, and showed that all the good effects of blisters might be secured by leaving them on for a much shorter space of time. I proved by numerous experiments, that in many cases it was not necessary to leave them on more than four or five hours, in the adult*, and that they might then be removed and the blistered part dressed with spermaceti ointment. Under this dressing the blister rises well, and there is no danger of tearing away the cuticle, or producing an irritable sore. In addition to this, you entirely avoid the irritating effects which blisters are known to produce on the urinary organs. You will very rarely meet with dysuria, or hæmaturia, where the blister has been left on for the spaces of time I have mentioned.

Blistering is then to be used with the restrictions I have mentioned, and you will find it a most valuable aid in the treatment of fever and its complications. It may be employed either as a derivative and revulsive, or you may have recourse to flying blisters over various parts of the body, in certain forms of fever, where there is marked and sudden depression of the powers of life.

Speaking of depression of the powers of life reminds me of a curious incident, which occurred some time since in my practice, and which shows the value

* In pulmonary diseases, this continued discharge is often very useful, and should be encouraged; but in fever the production of such an effect from blisters must be avoided, as a surface thus denuded of its cuticle and inflamed, may be converted into a dangerous sore.

* Of course, blisters applied to the scalp must be excepted. They require at least twelve hours. In old persons generally the skin is much less vascular than during youth and middle age; and consequently, in the old, blisters require a much longer time to produce the required effect.

of being acquainted with the peculiar habits and idiosyncrasies of families. I attended, with Mr. Kirby, about three years since, a gentleman of middle age and active professional habits, who had been attacked with fever. I was first called to see him on the ninth day of fever, and found him apparently moribund. His pulse was intermittent and irregular, the action of the heart tumultuous, the respiration feeble, and the extremities cool. Mr. Kirby had instantly ordered internal stimulants, and blisters over the region of the heart and epigastrium. The patient rallied, and ultimately recovered. It is to be observed, that the group of formidable symptoms just enumerated had supervened quite out of the usual course, and without any previous warning. They were consequently not only alarming but unexpected. About a month afterwards, Mr. Smyly and I were called to see this gentleman's brother, who was living at Dundrum, and who was supposed to have caught fever from his close attention to his brother during his illness and convalescence. What was most remarkable in the case, was, that his pulse began to flag and intermit, and he likewise suddenly and unexpectedly got the same symptoms of depression of the vital powers on the very same day and hour as his brother. His symptoms also continued for the same length of time, and yielded, or spontaneously ceased, under the same plan of treatment. In some families you will find a very curious coincidence between the play of the various functions in disease as well as in health, and you should neglect no opportunity of making yourself acquainted with the family peculiarities and idiosyncrasies of your patients, as knowledge of this description is of the greatest value and importance in the treatment of disease.

ON THE FORCES

WHICH REGULATE THE

INTERNAL CONSTITUTION OF BODIES.

By O. F. MOSSOTTI.

THE following are only the popular preliminary remarks of Signor Mossotti: we have borrowed them from the "Scientific Memoirs," Part III. just published, by Mr. R. Taylor. The reader who wishes to study the body of the paper—a most important production, but wholly mathematical—had better procure the valuable periodical referred to.

THE study of the phenomena of nature has led philosophers to consider bodies as being

composed of molecules held in a state of fixed equilibrium at a certain distance from each other. Such a state requires that they should be endued with a certain action. Some peculiarities of this action we are already able to assign, but its complete characteristics are not yet well defined.

As the resistance opposed by bodies to compression increases indefinitely with the reduction of their volume, though their molecules have not come into contact with each other, it shows that the force which they exercise is repulsive at the least distances. At a distance greater than these, but still imperceptible, it must vary with great rapidity, and become attractive, in order that a steady equilibrium of the molecules may be possible; and finally, when it has become perceptible, it must decrease in the inverse ratio of the square of the distance, in order to represent the universal attraction. The limits of the distance at which the negative action becomes positive vary according to the temperature and nature of the molecules, and determine whether the body which they form be solid, liquid, or æriform.

There is a class of phenomena, rather singular at first sight, in which, however, it appears that nature designed, by separating the forces which she employs, to present herself in all her simplicity. Such are the phenomena which constitute what we denominate *statical electricity*. It is well known with what admirable facility Franklin explained these phenomena, by supposing that the molecules of bodies are surrounded by a quantity of fluid or æther, the atoms of which, while they repel each other, are attracted by the molecules. It is known also how Coulomb subsequently proved that the force with which the repulsion of atoms and the attraction of the molecules are produced, is, like universal attraction, regulated by the law of the inverse ratio of the square of the distance. Indeed, the latter philosopher has substituted for the hypothesis of Franklin, which is that generally followed in England, Germany, and Italy, another hypothesis, in which a second fluid is supposed to perform the part assigned to matter in that of Franklin; and this mode of explaining the phenomena has been more generally adopted in France. It is even asserted that the latter hypothesis is the only one that should be received, inasmuch as it has been completely confirmed by the results of the beautiful analysis with which M. Poisson has begun to enrich the Memoirs of the Academy of Sciences. But they who put forward this assertion have not paid due attention to the fact, that, although this illustration

geometer has, for the purpose of establishing his calculations, adopted the language of his school, the inferences drawn from them are not more applicable to the one hypothesis than to the other. He sets out, in fact, with the principle, that "If several bodies, being electric conductors, are placed in presence of each other, and attain a permanent state, the result of the actions of the electric layers which cover them, on a point taken anywhere in the interior of a body, must, in that state, be null; otherwise the combined electricity which exists in the point under consideration would be decomposed; but this is contrary to the supposed state of permanence." Now if for this principle the following be substituted: "If several bodies, being electric conductors, are placed in presence of each other, and thus attain a permanent state, the result of the actions of the layers of electric fluid which cover them, and of the exterior layers of matter which are not yet neutralized, on the electric fluid at a point taken anywhere in the interior of a body, must, in that state, be null; otherwise the electric fluid which exists in that point would be displaced, which is contrary to the supposed state of permanence;"—and if we interpret accordingly the literal denominations employed by M. Poisson and his equations,—all his results will be equally true on Franklin's hypothesis. In general, the action of the condensed electric fluid will stand for that of the vitreous fluid; and the action exhibited by the matter, in proportion as it is deprived of a quantity of its electric fluid, will stand for that of the resinous fluid. There is one circumstance, however, which makes a difference between the hypothesis of Dufay or Coulomb and that of Franklin: it is this—that, according to the one, the two fluids are moveable in the bodies, while according to the other the electric fluid is, but the matter is not, moveable. As the equilibrium, however, requires that we should only regard the relative position, the mobility of the electric fluid alone is sufficient for its establishment.

Æpinus, who has reduced Franklin's hypothesis to the form of a mathematical theory, was the first to remark, that if it be the requisite condition for the equilibrium of the electric fluids of two bodies, in their natural state, that "the attraction of the matter and the repulsive action of the fluid of the first body on the fluid of the second should be equal, and *vice versâ*," there are but three forces in operation; two of which are attractive, and but one repulsive. In other words, each of the two bodies attracts the fluid of the other, while the mutual repulsion of the two fluids constitutes only a single force, equal

to each of the two attractive forces. If, then, with the equilibrium of the fluids, it is desired to find the equilibrium of the masses also, an equal repulsion must be allowed between the molecules; since the bodies would otherwise forcibly attract each other. But such an attraction is contrary to what we learn from experience. He felt at first a strong objection to the admission of such a repulsive force between the material molecules, as being opposed to the idea entertained of their mutual attraction, which was so clearly demonstrated on Newton's principles. But a little reflection satisfied him that this admission contained nothing that was opposed to facts, or, as he might rather have said, that was not confirmed by facts. Universal attraction itself may follow as a consequence from the principles which regulate the electric forces: for if we suppose that, the masses being equal, the repulsion of the molecules of matter is a little less than their attraction of the atoms of the æther, or than the mutual repulsion of the atoms themselves, this will be sufficient to leave an excess of attraction, which, being directly as the product of the masses and inversely as the square of the distance, would exactly represent the universal attraction.

While reflecting on these principles, in a course of lectures on natural philosophy which I gave at the University of Buenos Ayres, I conceived the idea, that if the molecules of matter, surrounded by their atmospheres, attract each other when at a greater, and repel each other when at a less distance, there must be between those two distances an intermediate point at which a molecule would be neither attracted nor repelled, but would remain in steady equilibrium; and that it is very possible this might be the distance at which it would be placed in the composition of the bodies. I thought the idea of sufficient importance to fix it in my memory, but did not at the time pursue its development further.

On my return to Europe I learned, through the reading of some memoirs, and in the course of conversation with men of science, that the attention of geometers was particularly directed to the molecular forces, as being those which may lead us more directly to the knowledge of the intrinsic properties of bodies. I was thus led to recall my ideas on the subject, and to set about subjecting them to analysis. The results of my first investigations I here submit to the judgment of philosophers.

I have supposed that a number of material molecules are plunged into a boundless æther, and that these molecules and the atoms of the æther are subject to the

actions of the forces required by the theory of Æpinus, and then endeavoured to ascertain the conditions of equilibrium of the æther and the molecules. Considering the æther as a continuous mass, and the molecules as isolated bodies, I found that, if the latter be spherical, they are surrounded by an atmosphere, the density of which decreases according to a function of the distance which contains an exponential factor. The differential equation which determines the density being linear, is satisfied by any sum of these functions, answering to any number of molecules. Whence it follows that their atmospheres may overlay or penetrate each other without disturbing the equilibrium of the æther. Proceeding in the next place to the conditions of equilibrium of the molecules, I observed, that for a first approximation (which may be sufficient in almost all cases), the reciprocal action of two molecules and of their surrounding atmospheres is independent of the presence of the others, and possesses all the characteristics of molecular action. At first it is repulsive, and contains an exponential factor which is capable of making it decrease very rapidly: it vanishes soon after, and at this distance two molecules would be as much indisposed to approach more nearly as they would be to recede further from each other; so that they would remain in a state of steady equilibrium. At a greater distance the molecules would attract each other, and their attraction would increase with their distance up to a certain point, at which it would attain a maximum: beyond this point it would diminish, and at a sensible distance would decrease directly as the product of their mass, and inversely as the square of their distance.

This action, possessing all the properties with which we can presume that molecular action is endued, is the more remarkable as it has been deduced from those forces only whose existence was already admitted by philosophers, and whose law is characterized by such extraordinary simplicity. When tested in the explanation of the varied phenomena which are proper to it, it must lead, in case of failure, to the exclusion of those forces from amongst physical principles; or, in case of success, establish their reality; and thus mark in a striking manner the admirable economy of nature.

To apply the formulæ which we have found, for the purpose of representing molecular action, to the phenomena of the interior constitution of bodies, requires methods of calculation which are not yet developed, and which must become still more complicated when the arrangement of the molecules, their form,

and their density, are taken into consideration. I have thought it advisable, however, in consideration of the use to which it might be applied by able geometers, not to postpone the publication of this mode of viewing molecular action. It is a subject which appears to me entitled to the greatest attention, because the discovery of the laws of molecular action must lead mathematicians to establish *molecular mechanism* on a single principle, just as the discovery of the law of universal attraction led them to erect on a single basis the most splendid monument of human intellect, *the mechanism of the heavens*.

We mentioned that Professor Faraday, in his popular account of Mossotti's law, at the Royal Institution, quoted a passage written nine years ago by Dr. Roget, in which the probability of the existence of such a law is alluded to. The following is the passage: it occurs in the treatise on Electricity in the Library of Useful Knowledge:—

“(239.) It is a great though a common error to imagine, that the condition assumed by Æpinus, namely, that the particles of matter when devoid of electricity repel one another, is in opposition to the law of universal gravitation established by the researches of Newton; for this law applies, in every instance to which inquiry has extended, to matter in its ordinary state; that is, combined with a certain proportion of electric fluid. By supposing, indeed, that the mutual repulsive action between the particles of matter is, by a very small quantity, less than that between the particles of the electric fluid, a small balance would be left in favour of the attraction of neutral bodies for one another, which might constitute the very force which operates under the name of gravitation; and thus both classes of phenomena may be included in the same law.”

EFFICACY OF THE STRYCHNOS NUX VOMICA IN AFFECTIONS OF THE DIGESTIVE ORGANS.

To the Editor of the Medical Gazette.

SIR,

IN a complaint occurring under so many and varied aspects, and not unfrequently bidding defiance to the best directed efforts of the practitioner, it will not, I think, be deemed an unprofitable ser-

vice if I shall have contributed in this brief communication any thing towards the more successful treatment of what has hitherto occasionally proved one of the opprobria of our art. Amidst the multiplicity of remedies with which the storehouse of our *materia medica* is at the present day so amply supplied (some of them, doubtless, of inestimable value, while others seem destined to possess a more ephemeral reputation), it becomes a gratifying part of our duty to endeavour to rescue from unmerited oblivion a therapeutic agent which has long been familiar to the medical world, but whose efficiency has been crippled by a too limited application of its powers;—I allude to the *strychnos nux vomica*. Very few, indeed, of the practitioners with whom I am acquainted are in the habit of employing this remedy otherwise than for the relief of certain forms of paralysis, where it has undoubtedly been productive of the most beneficial effects in some instances, as I have myself had occasional opportunities of testifying. In the valuable lectures of Mr. Pereira contained in the present volume of the *MEDICAL GAZETTE*, a very cursory notice is taken of this drug with reference to its effects in disorders of the alimentary canal, although its application to the cure of paralysis is fully and ably discussed. In the "*Pharmacopée Universelle*," too, which contains a great variety of formulæ for its several modes of exhibition, little mention is made of its properties and uses further than as they may be rendered subservient to the removal of the graver affections of the nervous system, such as paralysis, epilepsy, chorea, &c. It does, indeed, appear from the same work that M. Niemann had successfully employed, in what he calls spasmodic cardialgia, a pill composed of one-fifth of a grain of the alcoholic extract of *nux vomica*. This statement, however, is merely made incidentally, and without any importance being attached to the exhibition of the remedy as a curative means in the above deranged condition of the system. With the view, therefore, of endeavouring to extend its utility to another class of disorders, less immediately interfering, it is true, with the continuance of life, but frequently, when unalleviated at an early period, paving the way for the encroachment of a long catalogue of

organic changes*, that I am desirous of submitting these few remarks to the notice of the profession. The difficulty oftentimes experienced in the removal of dyspeptic ailments, and the consequent uncertainty attaching to each and all of the multiplied remedies which experience has proved to be alike in their turn available, must be generally admitted; and hence we are frequently doomed to witness the inefficacy of the most scientific treatment, whilst a cure is perhaps finally effected by the employment of some old woman's recipe. It is now several years since my attention was first struck with the very decided benefit resulting from the exhibition of this remedy in disorders of the digestive functions; and subsequent experience, which has certainly been ample, has tended only to confirm the confidence originally reposed in it. The cases in which it has been productive of the most decided benefit, are those of pyrosis, resulting from simple functional disorder of the stomach. In examples of this nature, indeed, I consider it almost a specific; so immediate, and in most instances so prominent, has been the relief obtained. I have the less hesitation in making this avowal, from having so frequently witnessed the almost total inefficacy of every means previously put in practice, and the patient consequently harassed with a vexatious disorder, depressing alike the energies of both mind and body. In pyrosis also, symptomatic of organic disease of the stomach, the powers of *nux vomica* are of essential service; although, of course, in this instance we can in general hardly expect to do more than regard the advances of those morbid changes which are going forward. It is not, however, for the removal of the above symptoms alone that I would restrict the employment of this remedy; although I believe, that in the subjugation of that symptom its virtues are more frequently and conspicuously manifested. In almost all cases of disordered digestion, unaccompanied with any inflammatory condition of the mucous membrane, and where the symptoms appear to depend upon a diminished vigour of the nervous and muscular powers of the stomach, as indicated chiefly by pain and distension after eating, acid eructations, &c.,

* See Dr. Wilson Phillip's work on Indigestion, *passim*.

the tongue frequently exhibiting little or no fur on its surface, it may be prescribed with the fairest prospects of advantage. In a decidedly febrile state of the system accompanying the dyspeptic ailments, I should of course consider its use contra-indicated. But if we attentively consider the phenomena of indigestion, I am fully persuaded that in a larger majority of cases we shall be sensible of the impropriety of having recourse to any antiphlogistic measures; but on the contrary of the expediency of endeavouring to impart a greater degree of tone to an organ already suffering from diminished excitation. From the experiments which have been made with *nux vomica* upon animals generally, and upon man, it is established that its first effects, when given in moderate doses, are those of an active stimulant to the nervous system, without producing any marked influence upon the pulse; whilst, if given in larger doses, its effects are manifested "by a disordered state of the muscular system;" and if persevered in still further, tetanus and asphyxia are the result. But without further allusion to its various physiological effects, I shall merely add, that however energetic a poison it may in some instances have proved, I have never found its exhibition, even in tolerably full doses, productive of the slightest inconvenience, either when given in the form of powder, extract, or tincture. And this leads me to remark, that of the three modes of exhibition above alluded to, that of the powder appears to be by far the best, as its effects are far more uniform and certain: this may be given in doses of three, four, or five grains, suspended in cinnamon water, with mucilage, to which an aromatic, as the *tinctura cardamomi comp.* may be added, or, combined with a little calumba; and carbonate of soda, in the form of a powder, three times a day. If, as is usually the case, costiveness be present, this condition may be best obviated by continuing with each dose of the remedies above indicated, two or three grains of the *pulvis rhei*: if, on the contrary, diarrhoea be an accompanying symptom, this state constitutes no objection to the employment of the *nux vomica*, which may still be exhibited, in combination with chalk or opium, until the healthy action of the bowels be restored.

I have here purposely abstained from making any allusion to those auxiliary remedies, to whose efficacy in correcting the depraved secretions of the intestinal canal multiplied experience has borne the most ample testimony—such as the several preparations of mercury—my object being rather to direct the attention of practitioners to the singular value of a therapeutic agent, without the co-operation of which their curative efforts, however scientifically directed, will now and then be frustrated. In order, however, that the efficiency of this drug be duly exemplified, it is very important that the powder have been recently prepared, and free from all adulteration. With this view I have generally been in the habit of laying a strict injunction upon the druggist to supply me with a genuine article, offering at the same time a somewhat higher price to insure this object, many of the specimens which I have met with having proved, upon trial, to be almost worthless.

I am unwilling to occupy more of your space by detailing any cases in which I have found the above remedy so very serviceable, particularly as I trust, from what has been already said, the indications for its use will appear sufficiently evident. Before concluding, I must not omit to mention that the late Dr. Belcombe, of York, was in the habit of employing the *nux vomica* for the relief of indigestion, but in what particular form of this complaint I am not at present prepared to say. Mr. Wass also, of Thirsk, prescribed it in similar cases, without however, so far as I am aware of, attaching any very great importance to its exhibition. I am happy in being able to add the testimony of Mr. Fawdington, of this town, in favour of its remedial powers; the latter gentleman having, in the course of an extensive practice, enjoyed repeated opportunities of verifying its utility, especially in the removal of pyrosis.

It now only remains for me to state, that in advocating the claims of a truly valuable remedy to the notice of the profession, as adapted to a class of disorders in which it has hitherto been very rarely tried, I am impressed with a strong conviction that, unlike many fashionable remedies of the day, it is destined to hold a very high rank in the

scale of our remedial agents, an anticipation which I hope to see in part realized, by its admission into a future edition of the Pharmacopœia.

I remain, sir,
Your obedient servant,
THOMAS MELLOR,
Demonstrator of Anatomy at the
Royal School of Anatomy and
Medicine.

Manchester, Feb. 15, 1837.

CASE OF TYPHUS FEVER—CONCUSSION OF THE BRAIN—AND GORING BY A BULL.

To the Editor of the Medical Gazette.

SIR,

THE publication of some cases I recently sent you, has induced me to communicate the following, thinking it may be interesting to many of the readers of your excellent journal,—to some of whom it may resemble a biographical sketch rather than the simple detail of facts relating to the medical history of an individual in the lower ranks of society, and for the greater part of his life the inhabitant of a retired country village.

Soon after I commenced practice, I received an order from the overseer of a neighbouring parish to that in which I resided, to attend some families afflicted with fever. In one of the cottages (a miserable hovel, containing only two rooms, one above and one below, and both badly protected from the inclemency of the weather,) I found two young persons already dead; another in the last stage of typhus, who expired during the ensuing night; and three or four others in different stages of the same disease, who subsequently recovered.

Although I had never before seen such distress in private practice, I had witnessed the direful effects of typhus fever upon an extended scale, having been one of the medical attendants on the sick and wounded troops who returned to Plymouth after the death of their lamented commander, Sir J. Moore, at Corunna. The treatment I had recourse to I will not detail, as it might render my communication unnecessarily tedious; suffice it to mention, that in

many respects it resembled that adopted by one of my excellent colleagues on that memorable occasion, and which he has so ably described in the fifth volume of the Edinburgh Medical and Surgical Journal.

One of my patients, who recovered, was a lad about ten years of age, named George James. The symptoms had been of an alarming character, and he had been considered to be in imminent danger.

A few months after his recovery, I was again called upon to attend him. He had fallen from a lofty tree, which he had ascended to take a rook's-nest; was taken up insensible, and in that state conveyed home. Upon examination, I could not discover any fractured bone, or any depression of the cranium. The dilated state of the pupil, and its incontractility on the admission of light, with other symptoms, denoted concussion of the brain; and I treated the case accordingly. The only sensibility he displayed, was taking into his mouth and swallowing what supplies of food or medicine were given him; and he was restless when necessitated to attend to the calls of nature. At first I gave him calomel and antimonials in combination, to which I added a strong infusion of senna, with small doses of the compound spirit of ammonia. When the pulse, which was at first feeble, increased in force and number, I had recourse to general and topical bleeding; at which times he would open his eyes and look about him, and then relapse into his state of insensibility. He continued in a similar state of torpidity, breathing without difficulty, and resembling any one in profound sleep, for above a week; when he gradually began to take notice, and at length to make inquiries respecting himself, having no recollection of any thing that had occurred after the branches of the tree had given way with him. He soon after regained his health and strength.

From this period I had no call to attend this unfortunate youth until he had attained the age of nineteen; but he had in the interim some narrow escapes, as he had connected himself with a gang of depredators who infested the neighbourhood; and, being detected in some burglaries, had sentence of death twice recorded against him, which was each time commuted for a term of imprisonment, on account of his youth.

On this occasion he had received a severe wound in the abdomen, from an enraged bull, which he had been occasionally in the habit of irritating; and being at work in the field where the animal was grazing, he commenced throwing stones, &c., when it closed upon him, and tossed him into the hedge. Fortunately for him, he fell on the opposite side, otherwise a second attack might have occasioned his death on the spot. He rose from the ground, with the intention of reaching the adjoining farm-house, but found that a considerable portion of his bowels were protruding through a wound occasioned by the horn of the bull; and, after calling for assistance, fell down, unable to proceed any further. In this state he was discovered and conveyed into the house. On my arrival, I found him reclining on a bed on the floor; his countenance pale, respiration quick, pulse small and very rapid, and a clammy coldness on the surface of the body, particularly of the extremities. The hæmorrhage had been very copious. Upon examining the wound, I found that it commenced about the centre of the right iliac region, and extended obliquely upwards, for five or six inches in length. The intestines were protruding in a considerable mass, equaling in size the head of a child eight or ten years of age, and consisted of nearly the whole of the colon, and at least two feet in extent of the ilium; but upon tracing them minutely, I could discover no other injury they had received, excepting a laceration of several of the mesenteric vessels, from whence the hæmorrhage had proceeded. The omentum, which appeared as if rent in several directions, was lying on one side. Having reduced the intestines, and extended the omentum over them as evenly as possible, I closed the wound, and secured its edges in contact with sutures, and straps of adhesive plaster; a fold of linen was laid over the dressing, and a band six or eight inches in breadth surrounded the abdomen, over which I directed a large compress to be applied, frequently wrung out of cold water. A degree of reaction taking place, as the pulse was increasing in force, I had recourse to venesection; and in this, as well as in the subsequent bleedings, was governed more by the effect upon the vascular system than influenced by the quantity of blood ex-

tracted. I directed his taking a solution of sulphate of magnesia every three hours, combined with small doses of the antimonium tartarizatum.

About seven hours after the accident I again saw him; his countenance was somewhat flushed; the pulse above 100, and full; the skin warm and dry; and the bowels had not been evacuated. I had again recourse to venesection, and directed a perseverance with the other means before recommended.

The following morning I found he had passed a tranquil night. The constitutional irritation, though somewhat increased, did not exist in any considerable degree; the tongue was covered with a white crust, and he complained of thirst; the skin was dry and hot; the pulse 110, and increased in hardness; the bowels had not been relieved, although he had voided his urine several times, and the surface of the abdomen betrayed an increased degree of tenderness. I bled him again, and directed a grain of calomel, and the same quantity of antimonial powder, to be taken every four hours, and a dose of a saline cathartic mixture in the intermediate time, and likewise the administration of the common domestic enema every four or six hours, with the repetition of the application of cold externally.

A call to a particular obstetrical case prevented my seeing him until the following morning (forty-four hours after the accident). I found him apparently in a hopeless state; his countenance was deeply flushed, and displayed a complete personification of anxiety, his sight being directed from one object to another in quick succession; he had been delirious at intervals during the night, a troublesome hiccup distressed him, and he had vomited several times. The skin was dry, and parched with heat; the tongue covered with a dark brown coating; the pulse very irregular in force and number, but averaging about 150 per minute; and the abdomen felt tense, and was excessively tender, as the slightest touch gave him severe pain. He told me he should die, and thanked me for the attention I had shewn him on this and former occasions. I directed an occasional dose of *ol. ricini*, which I subsequently found his stomach retained; the enemata to be continued, injecting a solution of sulphate of soda in strong infusion of senna, and to repeat the application of

cold water to the abdomen as frequently as could well be effected.

On my seeing him in the evening, he exclaimed with animation, "I am better, sir." His countenance was expressive of less anxiety; his skin felt softer, was cooler, and disposed to a gentle perspiration; the tongue was whiter and cleaner; the pulse regular, though much too full and quick; the other symptoms more favourable; and the bowels had been relieved several times. I directed the continuance of the cold applications, and the repetition of the oleum ricini, with his taking plentifully of whey and soft gruel, the only articles of diet he had taken since the occurrence of the accident. I had likewise recourse to another bleeding, abstracting the blood to a greater extent than at any time before.

The following morning I was gratified by finding considerable amendment. The pulse was about 90; the temperature of the skin lessened, and it was bedewed with a gentle perspiration; the abdominal tension was nearly gone, and the wound (which I now examined for the first time after closing it,) presented a favourable appearance. Several evacuations had taken place during the night. From this time the symptoms continued to improve, and my patient gradually recovered. On discontinuing my attendance, I ordered his wearing continually a wide band or belt, by way of support and protection; and also cautioned him to be attentive to the state of his bowels, carefully avoiding a state of constipation, and whatever would be likely to occasion irritation.

A few months after his recovery he left the neighbourhood for London, where he married and resided three or four years; when he again returned to his native place. Some time afterward I received an urgent request to visit him as expeditiously as possible. I went immediately to his house, but he had expired before my arrival. He had suffered extreme pain in his stomach and bowels, with great sickness and relaxation. The abdomen was somewhat distended and tense, but the body did not present any external appearance of injury. I left the house, saying I should call the next morning to make a further examination of the body. Meantime it was reported he had been poisoned by his wife; and the following

morning I was requested to attend a coroner's inquest, who were assembled to investigate the affair. I went accordingly to meet the coroner and jury, and having stated what I knew of the case, proceeded thence with my assistant to examine the body.

Upon laying open the abdomen, the intestines appeared extensively inflamed, but more so on the right side than on the left, the mesenteric vessels being full or distended, and the peritoneum reddened in several parts. At the part where he had been wounded by the bull there was a deficiency of the peritoneal lining of the abdominal parietes, the internal parts being simply covered by an expansion of integument, for an extent of five or six inches in length, by two or three in breadth. We removed the stomach and duodenum, with portions of the intestines, and examined their contents; and being unable to detect any poison, we called upon the coroner and jury to request their adjournment till the following day, in order to allow us time for a deliberate examination by tests, &c. We conveyed the stomach, &c. home; and after a minute examination by tests, and employing every method of analysis for the detection of poison, as recommended on such occasions, without success, we made our report to the jury, who, without much hesitation, returned a verdict of—"Died by the visitation of God."

The only account given by the wife relative to the sudden illness of the deceased, was, that he had gone to work at a stone-quarry without wearing his belt, and that he had drank a quantity of cider, a beverage to which he was unaccustomed.—I am, sir,

Yours very respectfully,
J. F. HULBERT.

6, Trinity Square, Southwark,
Feb. 7, 1837.

TREATMENT OF HYDROCELE BY IODINE.

To the Editor of the Medical Gazette.

SIR,

THE following observations exhibit the good effects produced by iodine in a case of hydrocele, no other remedy having been ever employed for the cure of the disease in this patient.

I had intended to have transmitted this case for your notice soon after the cure had been accomplished. I could not, however, at that time give an account of any other similar case in which the effects of iodine had been established; since that period I can bear testimony to the same favourable result in two other cases; and at this present time I have another case (which has existed for the last seven years), under similar treatment, doing well. I have had my attention drawn to this particular case (the account of which I now have the pleasure of forwarding to you), from having the same patient at this time under my care, he having recently met with an accident, the consequence of which has been phlegmonous erysipelas of his right hand and arm. It is more than sixteen months since he was cured of the hydrocele, and he has not experienced any symptoms of its return.

I consider these facts worthy of remark; and if you coincide with me in this opinion, perhaps you will find space for them in your journal.

I am, sir,
Your obedient servant,
CHARLES CASWALL.

18, Woburn Place, Russell Square,
Feb. 21, 1837.

William Soper, æt. 58, a stout robust man, employed by Messrs. Tyler and Co., the extensive coppersmiths in Warwick Lane, became a patient of mine on the 4th of June, 1835, with a hydrocele about the size of the egg of an ostrich. The fluid had been accumulating for the previous twelve or thirteen months, and was perfectly transparent. No remedy whatever had been employed to remove it, neither had any but the operation of tapping been suggested; and to this the patient was greatly averse. I therefore recommended him to pursue the following treatment:—

June 4th.—R Pulv. Jalapæ, gr. xij.;
Hydrarg. Submur. gr. iij. M. cras mane.

6th.—R Ung. Potass. Hydriod. 3j.

This portion of ointment to be rubbed into the scrotum every night and morning, and at all other times some of the ointment to be spread on lint and applied around it (the scrotum, of course, to be constantly suspended in a bandage.) The ointment was composed in its proportions, of one drachm of the

hydriodate of potash to one ounce of hog's lard.

11th.—Rep. Ung. et Pulv. Cath.

16th.—Rep. Ung.

R Træ. Iodinæ, ℥xx. ter quotidie ex
Aq. Distill. ʒiiss.

23d.—Rep.

July 2d. — Tinct. Iodinæ, ℥xxx. ut
antea sumend.

11th and 21st.—Rep.

Aug. 1st, 13th, and 25th.—Rep.

Sept. 3d and 12th.—Rep.

Oct. 3d.—Cured.

The patient was considered quite well on the 12th of September, but he was desirous of continuing the same remedies for a short time longer; he has desisted employing them, however, since the 3d of October. The treatment of hydrocele by tapping and subsequent injections is not at all times unattended by danger. I witnessed on one occasion death ensue in consequence of this treatment, at St. Bartholomew's Hospital. I am not aware of any ill effects succeeding to the use of iodine in this disease, which can be in anywise attributed to its employment.

P.S.—I dated this communication as if written on the 21st of this month, not intending to send it to you till that day. It was written, however, yesterday (Feb. 17th); and it is somewhat singular that, in perusing your GAZETTE of this day, I find two letters, one from Mr. Keate, and another from Mr. Lewis, on the treatment of hydrocele by puncture. Perhaps the mode of treating this disease as here prescribed, may supersede that of puncture.

Feb. 18, 1837.

A COMBINATION OF PATHOLOGICAL STATES,

OCCURRING IN ONE AND THE SAME
INDIVIDUAL.

Hydatids and their Origin.

To the Editor of the Medical Gazette.

SIR,

I SEND you the following case for insertion, if you think the variety of morbid appearances co-existing therein sufficiently curious to merit a place in your journal.

John Kemp, æt. 68, labourer, was admitted into the Birmingham Dispensary

In October last, with fever, yellowness of skin, pain in right hypochondrium, and cough—in short, with the usual symptoms of acute hepatitis, for which he was bled with leeches to the anus, and over the side, with great relief. Still the pain and tenderness, though lessened, were not removed, and the cough continued unabated, with great dulness on percussion, over the lower part of the right side, and with absence of the respiratory murmur. Similar attacks recurred frequently, and were relieved by the same means; but as the cough on each occasion became worse, though there was no decided crepitation, nor were the sputa mixed with blood, I changed the diagnosis from hepatitis to pneumonia. The last attack occurred about three weeks ago, with intense pain and tenderness over the whole side; urgent dyspnoea, so that he could not lie down; dulness on percussion over right side of the chest, with absence of respiratory sound, and *egophony* opposite the middle lobe, and *puerile* respiration over the left side. The sputa were rusty, and very viscid. He had leeches to the side, and took Ant. Tart., and the next day the subcrepitant or mucous rattle was heard over the front and upper part of the right lung; below which, behind, the *egophony* continued, and below that, all was dull. In a few days afterwards, the *egophony* had ceased, and nothing but a mucous rattle was heard at the upper part of the lung, before and behind. From this time his strength gradually failed, and he died on the 9th inst., after a violent attack of dyspnoea, his side continuing very tender to the last. Some years ago he had a paralytic attack that affected the muscles of the right side of the face, so that he had no power to close that eye, which remained wide open even during sleep, and was unable to whistle or blow, the cheek being quite flaccid; and for some time before his illness, his appetite had failed, and he had some difficulty in swallowing, and often vomited his food, which gave him great pain. During his illness, and particularly towards the close, his urine was very scanty, and nearly ceased for a few days. He always lay on his right side.

Section cadaveris, seventy-two hours, p.m. — Body not greatly emaciated; chest barrel-shaped, as usual in persons

from the absence of flatus in the intestines. Upon raising the sternum and false ribs, the former broke off below the clavicles, and exhibited its cancelli, filled with a bloody purulent fluid, which also was observed in the ribs, which were extremely brittle, and easily cut with the cartilage knife. The right side of the chest was quite dull on percussion. The sternum having been removed, a large substance was found occupying the right side of the chest, and projecting downwards as far as the kidney that adhered to it. It was covered at its upper and front part by the condensed and flattened lung, and at the lower portion by the right lobe of the liver, which, from the thickness of about an inch at the fissure, was thinned and flattened out over the tumor, till at its edge it was only $1\frac{1}{4}$ inches thick; the middle portion was covered by the adherent pleura and diaphragm. Not being able to remove the contents of the chest in consequence of their firm adhesions to the tumor, I opened it, when it flowed a quantity of hydatids, which, when all collected, filled a common wash-basin. They were of all sizes, from a turkey's egg to a grain of sand, and contained either a yellow or a limpid fluid. In many that were not burst, smaller ones, containing the yellow fluid, might be seen floating about with shreds of the lining membrane. They were all ovoid or globular, and without pedicles, but some were spotted on their surface with a single opaque spot. The large were grey and opaque, the middle sized transparent, and the smallest yellow, the colour of oil. The cyst being removed, was found to be formed by the peritoneum below, and by the diaphragm and pleura above, consisting externally of a dense laminated membrane, $1\frac{1}{8}$ th of an inch thick, covered internally with plates of calcareous matter, from one to three inches in diameter, and lined with thick layers of condensed lymph. The right lung was not so much condensed as to sink in water; and between its lower edge, all round, and the cyst, was a layer of lymph opposite the part where *egophony* was heard, and extending forwards to the pericardium. In the cells of this lymph were a number of hydatids, exactly similar to those contained in the cyst. The left lung was hypertrophied, and rather emphysematous, and the

clogged with mucus. The heart was natural, and contained some ante-mortem clots. The aorta was ossified half an inch square at the arch, with commencing ulceration and dilatation.

The stomach was large, and, about four inches from the pylorus, at the lesser curvature, was a round elevated ulcer, with sharp edges, 1-4th of an inch thick; the bottom being formed by the hypertrophied transverse muscular fibres. There was another ulcer close by, which had not perforated the mucous membrane, and was covered with pus; and another in its commencement at the pylorus, which was much thickened. The mucous membrane was generally congested and thickened, but not softened. The left lobe of the liver was twice its usual size, and lay in the left hypochondrium. It had the nutmeg appearance, but there was no difference in the texture of the two lobes. Both the liver and lungs were friable. The middle portion of the right kidney was softened, mottled, and had lost its tubular state. The left was healthy, but was compressed by the liver into a triangular shape. The spleen was healthy. The intestines and brain were not examined.

Upon further inquiry, I ascertained that the patient had been subject to pain in the right side for thirty years, and, about fifteen years ago, had broken one of his ribs on that side. The paralysis of the seventh pair came on suddenly one cold night, while he was going to his club, and was unattended with any apoplectic symptoms.

Upon a close examination of the hydatids, I found that the major part were collapsed and empty, but entire. The largest consisted of three coats easily detached from each other, and contained numerous smaller hydatids, and atheromatous matter, besides a number of minute yellow cysts, the walls of which were composed of cholesterine, coloured by the yellow fluid within; which, at a cursory view, I had previously mistaken for a gelatinous matter. I established the fact of the unbroken state of the empty hydatids, by piercing them with a blow-pipe and inflating them.

As the foregoing case exhibits a coincidence of a great variety of pathological states, and appears to me to add somewhat to our knowledge of the obscure subject of the degeneration of

tissues, I venture to append the following remarks.

All the authors I have consulted upon the subject of hydatids, describe them as containing a limpid fluid, colourless, or yellow, when the liver is the seat of disease; and Cruveilhier, whose account in the *Dict. Pratique* is by far the most complete, says that they are always included in a parent cyst, which lines the dense and fibrous one that is formed around them. He also rejects entirely the notion that they owe their origin to inflammation. In this case there were very few, out of some thousands, that were not empty, or nearly so; indeed, had they been full of fluid, the sac could not have contained the tenth part of them: besides that, they were carefully ladled out with a saucer, and their integrity was proved by the blow-pipe. There was no "mother cyst," and all the larger cysts contained atheroma, and so much cholesterine that the fingers were spangled over by it, and felt greasy after touching them. Not having an opportunity of consulting their works, I cannot say upon what grounds Vitel and Jager support their opinion of the inflammatory origin of hydatids, nor does Cruveilhier mention them; but in none of the numerous cases quoted by him is there reason to believe that the disease was of recent occurrence, nor is the recent effusion of lymph in the part ever mentioned. Yet, in the case above, although the first deposition of hydatids was probably referrible to the injuries sustained many years before, the second (indicated by the acute pleuropneumony, with effusion of fluid and lymph, as diagnosticated by auscultation and percussion,) could not be considered to be of older date than the last attack, three weeks before the death of the patient. The lymph occupied the most dependent part of the right pleural cavity, and was quite soft and flocculent, having all its areolæ filled with hydatids of a small size, very few of which contained any fluid. All these circumstances are in favour of the recent production of the hydatids; and this idea is borne out by a comparison with Mr. Sherwin's case, in vol. xix. of the *Edinburgh Medical and Surgical Journal*. In this case, the tumor was punctured several times, at about a week's interval, and Mr. S. remarked, that after the first two evacuations of the contents, the hydatids were much

smaller, though almost as numerous as before; and therefore he concludes that they had been formed between the operations. This is the only case I have been able to find in which the date of the origin of the hydatids can be fixed within any certain limits; except one which occurred in my own practice, where the patient began to expectorate hydatids just two months after two acute attacks of pneumonia, with intercurrent pericarditis, which occurred during salivation, and left a permanent bellows-sound. In this instance, also, the cysts were collapsed and empty, and admitted of inflation. A quantity of pus, but no serous fluid, was expectorated with them. From Mr. Sherwin's and my own two cases, therefore, I should conclude, in opposition to Cruveilhier, that inflammation has considerable influence upon the production of these parasitic animals, and that there may be an hydatid as well as a cancerous or scrofulous diathesis, &c. This brings me to the other interesting points of this case,—viz. the deposition of calcareous matter in the cyst, the cancer of the stomach, and the existence of Bright's disease in the kidney. But as I have already trespassed considerably upon your columns, I will leave the consideration of these morbid states to another occasion.—I remain, sir,

Your obedient servant,

T. OGIER WARD, M.D.

Physician to the Birmingham Dispensary.

Birmingham, Feb. 12, 1837.

FRENCH MIDWIFERY PRACTICE.

To the Editor of the Medical Gazette.

SIR,

IN looking over my note-book of last year, I find a few remarks which may possibly interest those of your readers who practise midwifery, as showing that there still exists a considerable difference between our practice and that of our continental friends, particularly as to the kind of instruments used in delivery, and the manner of employing them.—I am, sir,

Your most obedient servant,

GEORGE S. LILBURN, M.D.

24, Harley Street,
Feb. 23, 1837.

ROUEN.—The Hôtel Dieu, in this city, contains 600 beds. One ward is appropriated for women during their confinement, who are admitted by the physician, and kept as long as he thinks judicious (generally one month). The woman, when in labour, is taken into a small room, and there delivered on her back, with the head and shoulders a good deal raised, in the presence of the pupils. Immediately after delivery she is carried to a room appropriated for her reception, and the infants to one adjoining. In that for the latter their little beds are arranged round the room with canopies; they are dressed in swaddling clothes, confined all but their arms. One woman had been delivered the day before I arrived with forceps (Baude-logue's). She had lacerated perineum, and laceration through the vagina into the rectum. The Interne, who accompanied me round the hospital, and very politely explained the whole progress of the case to me (bringing me specimens of the instruments then in use), said, that the accoucheur, in employing the forceps, although a very powerful man, and exerting the whole of his strength, had the perspiration running down his face, and was more than an hour in extracting. The ergot had been previously given, and the patient bled largely.

I remarked that the mischief might probably have been avoided by the patient lying on her left side, and by the use of the curved forceps, invented by Dr. Osborne, and modified since his time, as there was no deformity of the pelvis.

He told me that perforation of the head of the child, when necessary, was effected with a long sharp-pointed bistoury, and the brain removed principally by the operator's fingers!

PARIS.—The Hôpital de la Maternité, for the reception of women, married or unmarried, during their confinement, who are attended gratuitously. No male pupils are allowed in the house. This establishment is intended for the instruction of "Sages-Femmes pour tous les Départemens du Royaume." The patients may keep their children, or, if they prefer it (no rare occurrence), send them to the Hôpital des Enfants trouvés. Five of these unfortunates were being sent when I first visited the hospital. They were enclosed in a sort

of partitioned box, with a high lid, and a blanket over each. The infants, when not sent away, remain in the same room with their mother, but in separate beds, with canopies; those of the latter without.

The physicians are—

Mons. Dubois, Méd.-en-Chef.

— Moreau, } Médecins.
— Jerardin, }

Mde. Le Grand, 1re Accoucheuse.

There were 96 female pupils, who remain from one to two years in the house. Mons. Dubois gives them clinical lectures and examinations; and from the great reputation of this accomplished physician, his instruction must be valuable. Mde. Le Grand lectures every day on the theory and practice of Midwifery, and the Pharmacien-en-Chef twice a week on Botany. Patients may get out of bed the fifth day, and the ninth day may sit up. For the first five days after confinement, if every thing goes on well, and the woman suckles her child, she is allowed, per diem, 2 pints of soup, 1 ditto potage, and 1 ditto bouillon at night; after the fifth day, meat and wine. Women are admitted as patients at all times before labour, night or day, without recommendation. Madame Le Grand employs the forceps when requisite, and all the pupils are taught to bleed and vaccinate. Fifteen grains of the ergot is the common dose, and Mons. Dubois only is allowed to give it.

In 1000 patients the instruments are used about 40 times.

I was indebted for my admission to the hospital to the politeness of Mons. Jourdan, Inspector-in-Chief of Hospitals.

A FEW REMARKS

ON

M O L L U S C U M ;

WITH TWO CASES OF MOLLUSCUM NON-CONTAGIOSUM.

By WALTER DICK, M.D.

Formerly House-Surgeon to the Glasgow Infirmary.

DR. BATEMAN, who was the first to particularize Molluscum, has described two varieties of it, apparently little

allied to each other—the Molluscum contagiosum, and the Molluscum non-contagiosum. Notwithstanding his acknowledged acumen in observing and diagnosing cutaneous diseases, Mons. Rayer is of opinion that the two cases, which he details as instances of contagious molluscum, were nothing else than a diseased state of some of the sebaceous follicles. It is much more probable, however, that Bateman was correct, in viewing them as cases of a distinct disease; and this view has subsequently been strengthened by Dr. Carswell, who (as we learn from Caze- nave and Schedel) had an opportunity of observing a case in every respect analogous to those described by Bateman. It occurred in a child, to whom the disease seemed to have been communicated by his brother, who had received it at school from one of his companions. The child died; and as the nature of the disease is altogether obscure, it is unfortunate that Dr. Carswell, so justly distinguished for his pathological researches, was not permitted to examine the structure of the molluscous tubercles.

This variety of the disease is characterized by sessile tubercles, seldom larger than small beans, which, according to Dr. Bateman, discharge a small quantity of milk-like fluid on pressure, from minute orifices in their summits. This fluid he presumes to be the medium of contagion.

The non-contagious molluscum is characterized by tumors of various sizes, some of them as large as a hen's egg, or larger even. This variety of the disease does not seem to have been observed by Bateman. As an instance of it, he alludes to the remarkable case described by Professor Tilesius*. One of the cases which we have met with was so similar to it, that the plates which Tilesius has given of his patient would, with a few trifling alterations, exactly represent ours; and we think ourselves fortunate in having had an opportunity of examining the texture of the tumors.

Dr. Bateman states that molluscous tubercles contain atheromatous matter. He does not seem, however, to have had any warrant for saying so; and we have ascertained that such is not the fact, in

* Historia Pathol. Singularis Cutaneæ Turpitudinis. 1793.

non-contagious molluscum at least. Hitherto, so far as we are aware, no anatomical description of the disease has been made public, unless, with M. Rayer, we suppose the disease, which M. Velpeau has described under the title "*tumeurs spéciales de la peau*," to have been molluscum, which it does not seem to have been.

It is probable that several dissimilar diseases have been described under the title molluscum, as is generally the case with complaints of infrequent occurrence. And some may perhaps say that the cases given below are not instances of molluscum. However, as Dr. Bateman has applied that term to the disease described by Tilesius, and as we find that our cases, particularly the first, agree so exactly with it, we think that they may with propriety be ranked under the same name, although, at the same time, we are of opinion that the disease cannot, without grossly violating cutaneous nomenclature, be ranked as a tubercular disease. Rayer has done right in removing it from the *Tubercula*, and placing it with those diseases which he comprehends under the head of "*vices de conformation de la texture*."

Our first case occurred in a Highland woman, unmarried, aged 36, a native of Skipness. She was admitted into the Glasgow Royal Infirmary, in September 1834, more as an object of curiosity than from any prospect of her being benefited by medical treatment. Her case was entered by me in the hospital journal. Her state on admission was as follows:—

Face is thickly studded with tubercles, varying in size, from a barley-corn to a small bean, of a round or oval form, with broad bases, and of the colour of the surrounding skin. Some of them are slightly transparent, so that they have some resemblance to bullæ at a distance. They feel soft, and most of them can be pressed nearly level with the surrounding skin, but immediately rise again when the pressure is removed. On left eye-brow there is a very prominent one, of the size of a Spanish nut; it feels firm, and is of a light-red colour. When cut into (which was done to ascertain its structure), nothing but blood flows from it. This is the case with some of the others which were similarly treated. They all appear to be solid.

Scalp presents a furfuraceous appearance, from chronic eczema. The tubercles of face are influenced by the state of this eruption, becoming rather larger when it becomes more active or irritable; they then occasionally discharge a little watery fluid, but not from visible orifices. There is a solitary tubercle, about the size of a pea, on centre of palate, covered with healthy mucous membrane.

At vertex capitis there is an elevation of the scalp, denuded of hair, of the size and shape nearly of an ordinary-sized watch. Over anterior part of sagittal suture is another similar protuberance, but rather smaller. Both have a tense elastic feel, as if they contained matter. This, however, on puncturing one of them, is found not to be the case.

Scalp over origin of trapezii muscles is a good deal thickened, hard, and intersected with pretty deep transverse rugæ. Has some uneasiness in this part. Neck and trunk of body, both before and behind, but particularly the back, are covered with an almost countless number of tumors. On the neck they are small; on the shoulders and upper half of back they vary in size from a pea to a pigeon's egg. A few of them have narrow necks, and are slightly pendulous; the rest have broad bases, and are of a semi-spherical appearance; some are soft, others rather hard to the touch. They have all more or less a reddish appearance. On lower part of back and haunches they are very numerous, and fully larger than those above, but possessing the same appearance.

On breast and belly the tumors generally are not quite so numerous as on back, and feel softer. Attached to inside of left mamma there is a pendulous one, of a pyramidal form, nearly the size of the fist, soft, and somewhat flaccid, containing a congeries of small pea-like bodies, apparently the lobules of the mammary gland enlarged.

Lower extremities below upper third of thighs are free of tumors. On upper extremities they are pretty numerous, and about elbows and wrists unusually large. One over lower extremity of left radius equal in size to a goose-egg, and has a soft spongy feel; the others vary in size, from a walnut downwards.

There is a vesicular eruption, of an eczematous appearance, over body, which has existed for two years back.

With the exception of tingling pain and itching from it, and the occasional uneasiness felt in tumors on head, she feels well. The tumors on trunk and extremities give her no uneasiness.

Her hue of skin is naturally dingy. General health good.

Her parents are healthy Highlanders, and none of her relations have been affected with any similar complaint.

All the tumors, with the exception of those on face, have existed since birth, and have gradually increased to their present size. The tubercles on face appeared between five and six years ago; for the last two years they have been stationary.

As it was deemed of importance to ascertain the structure of the tumors, she was persuaded to allow one of them to be removed. One, about the size of a walnut, on lumbar region, was selected. An elliptical incision was made, and tumor, which was attached to the subcutaneous cellular tissue, without any distinct cyst, was dissected out, its base requiring to be divided with the scalpel. The wound, after a slight attack of erysipelas, healed kindly.

On examining tumor, skin covering it was found firmly united by subjacent tissue. It was not thickened, and its texture seemed normal. The substance of the tumor itself seemed firm and solid. A section of it showed that it was composed externally of dense cellular tissue, of a light colour, resembling in some measure fibrous tissue. More internally, its structure was less dense, and appeared merely cellular tissue, with a little fatty matter. In fact, the tumor appeared to us to be a sort of hypertrophy of the subcutaneous cellular and adipose tissue.

This poor unfortunate woman, after remaining a week or two in the hospital, was dismissed in same condition as when admitted, excepting the eczematous eruption, which was cured by appropriate treatment, prescribed by Dr. Burns, under whose charge she was.

With respect to the tubercles on the face in the above case, it may be doubted by some whether they were the same in structure as those seated on other parts of the body. We have not had an opportunity as yet of seeing the Grecian elephantiasis, but, judging from the descriptions given of that disease, the facial tubercles of our patient did bear some resemblance to those which cha-

racterize that disease before it has made great progress; and had the tumors on head, and thickening of scalp at nape of neck, appeared simultaneously with them, we might have been inclined to believe that our patient had elephantiasis superadded to her molluscum. But when we know that the tumors and thickening of the scalp long preceded the tubercles on the face, we are led to think that the latter ought to be considered in their nature the same as those seated on the other parts of the body.

The second case occurred in a woman between 30 and 40 years of age, who was admitted with paralysis shortly after last patient. On her breast, shoulders, and back, there was a considerable number of tumors, varying in size, from a pea to a filbert; some of them a little larger. They felt soft. Some had broad bases, but the majority were pendulous, with narrow necks or pedicles. They generally were of the colour of the surrounding skin. A few small ones of similar characters on scalp, and one or two on side of face. They had existed from birth.

She died a few days after admission of the head affection for which she was admitted; and an opportunity was thus obtained of examining the structure of the tumors which were scattered over her body.

Their structure was found very similar to those of last case; and to be more particular in their description, would be just to repeat what we stated respecting the previous ones.

As already stated, the first of these cases bears an exact resemblance to the one described by Professor Telesius. We may shortly notice a few of their more remarkable coincidences. In the German's case, as in ours, there was a large tumor extending, as he says, "*ex scrobiculo cordis et a processu xiphoidæ sterni usque ad regionem umbilicalem.*" It was purse-shaped ("*marsupiformis.*") In our patient we remarked that the tubercles on the face at times became irritable, and discharged a little watery fluid. In Telesius's case something analogous to this occurred, but at more regular intervals: generally every month, he states, some of the tumors were attacked with sense of formication, and on friction "*humor quidam acrimoniosa lymphæ infectus effluit.*" On the head of this patient there was a

tumor of the same appearance as those which our Highlander had on her's. He, too, was born with the disease, of healthy parents.

Tilesius did not ascertain the structure of the tumors, as the man (perhaps wisely enough) would not consent to have any of them either punctured or excised. We have no doubt, however, that if they had been examined, they would have been found such as we have described, and not atheromatous, as Bateman, and some other authors, unadvisedly affirm. "The disease," says Tilesius, "a lymphæ trahit originem." This statement does not seem either very satisfactory or intelligible. Its etiology is altogether obscure. May not these congenital humours depend upon some modification of the "nisus formativus?" Will the transcendentalists be able to throw any light on this subject?

The above cases, in a practical point of view, are of no value, but as they may prove interesting to those who are especially engaged in the study of cutaneous diseases, and perhaps also to the general pathologist, we have been induced to record them.

Glasgow, Feb. 1837.

ERYSIPELAS;

ITS NATURE AND APPROPRIATE TREATMENT.

To the Editor of the Medical Gazette.

SIR,

DR. FORDYCE, Dr. Wells, and the subsequent physicians of St. Thomas's Hospital, were, I believe, among the first to establish by many striking instances that erysipelas was propagated by contagion. This doctrine has received much valuable support from Dr. Cullen, Dr. Baillie, and from many other quarters, and is now universally admitted by the medical officers of this institution, and I think I may venture to assert also, by the majority of the profession in this country. As this subject involves important consequences, it is not perhaps unnecessarily multiplying facts in proof of the highly contagious nature of this disease, to mention a few cases of recent occurrence.

Ann Verdon, aged 64 years, was admitted into Dorcas ward, on the 9th of June, 1836, with indolent ulcers of the

leg. In the adjacent bed there was a patient convalescent from an attack of erysipelas, which had commenced on the 24th of May. On the morning of the 19th of June, Verdon was attacked with erysipelas of the face. The disease followed its usual course, and lasted about five days, extending to the head, neck, and shoulders, while the constitutional symptoms ran high. She was successfully treated by wine, and from my notes I find that the cuticle of the affected part was desquamating, and she was completely convalescent on the 26th. As the general health of this patient, at the time of her admission, was good, I apprehend no doubt can exist of the disease, in this case, having been occasioned by contagion.

Philadelphia Rason, aged 50 years, whose thumb had recently been amputated in Dorcas ward, whence she was removed to Naples ward on the 3d of May, at the opposite extremity of the hospital. In this latter ward erysipelas had prevailed for some time, and she remained there until the 11th, when she returned to Dorcas ward. On the 29th, without having been exposed to any fresh source of contagion, she was attacked with erysipelas of the face, which spread rapidly over the head and upper trunk, attended with much constitutional excitement. This patient was also put on wine, and the case terminated favourably about the fifth day.

Two other patients also who were removed with Rason from Dorcas to Naples ward, likewise on their return to Dorcas fell ill of erysipelas within two days of the case recorded; they were similarly treated, and with the same happy result. I presume, therefore, that the three last cases must have been infected in Naples ward, and that the period which elapsed from the time of their leaving Naples ward to the appearance of the disease, is quite explicable on the ground of the latency of the poison.

The number of instances which are thus fast gathering around the doctrine of the contagious nature of erysipelas, have satisfied my mind that it is founded in truth; and I am equally convinced, from all I have seen, that it follows as a necessary consequence that bleeding is the exception, and not the rule of treatment of the class of diseases to which it belongs. But although vene-

section may not be the rule of practice, it does not result that a tonic plan is necessarily successful. I have on this account been induced to pay much attention to the cases of erysipelas treated during the last year in St. Thomas's Hospital, and I apprehend that in the following facts the most sceptical mind must find strong reasons for believing that the tonic treatment, if it still leave something to be desired, is certainly the most efficient of all the modes yet received by the profession.

From January to June inclusive of last year, thirty-two cases occurred in this hospital which were treated by wine, either alone, or combined with tonics, from the first appearance of the disease, and all, except two, recovered; of the two that died, one, in consequence of her late admission into the hospital, did not receive any treatment until a late period of her attack, and rapidly sunk; while the other was a woman far advanced in ovarian dropsy, and considerably emaciated, so that her life must have closed in a few weeks, had she not sunk under the severe form of erysipelas with which she was seized. At the time the above cases were treated by wine, I had an opportunity of witnessing several others treated after the antiphlogistic manner, and on a comparison of the results of the two systems, I should most unequivocally say that the wine or tonic plan of treatment was infinitely the most successful.

It appears, however, from your journal of the 7th and 14th of January last, that the treatment of erysipelas by wine has not been confined to St. Thomas's Hospital, but that Dr. Graves, of Dublin, also a contagionist, either by a happy coincidence, or in consequence of the lecture on this subject published by Dr. Williams, in the St. Thomas's Hospital Reports, has adopted a treatment essentially the same, or by wine and quinine enemata, and with such success, as that out of twenty cases only one died. Dr. Graves also states that this patient was at the time of attack labouring under fever, with dangerous cerebral symptoms, and which consequently greatly diminished the probability of the patient's recovery. I have Mr. Hewlett's* permission also to state, that since reading Dr. Williams' lecture, he

has adopted the treatment there recommended, and he informs me with the best effect.

Here are, then, upwards of fifty cases with only three deaths, and those occurring in patients whose condition was hopeless from the first, either from neglect of all treatment, or else from previously existing disease. I submit, therefore, that they are in sufficient number to constitute a body of evidence, supported as it is by many authors of the highest repute, fairly establishing not only the great utility of a tonic treatment, but also, as a general principle, its superiority over the antiphlogistic practice.

In opposition to this principle, it has been contended by one learned critic, that every case of erysipelas ought to be treated according to the symptoms. The objection to this rule I conceive to be, that no disease depending on a morbid poison has ever yet been successfully treated by following up the symptoms, as it is termed; neither do I imagine, except in very extreme cases, that we possess any such satisfactory prognosis as will enable us to determine on the first appearance of idiopathic erysipelas, what will be its course or termination.

Another authority has contended, that, whatever may be the success of this treatment in London, it will not do in the country; here I think the ingenuity of the party has been displayed at the expense of his discretion; for what must we think of medicine, if its laws and principles change in every district? Can it be true that within the circuit of the walls of Chichester or Warwick, quinine, mercury, hydriodate of potash, &c. produce other effects than the same medicines when exhibited in London? I should think not. And I feel satisfied that the pupils of St. Thomas's Hospital, or of the metropolis generally, will not have to unlearn in the country, *as erroneous and injurious notions*, those principles of treatment in erysipelas which they have seen so successfully practised in London: but I must apologize for trespassing so long and so often on the columns of your valuable journal.

I am, sir,

Your obedient servant,

HENRY BULLOCK.

St. Thomas Hospital.

* Surgeon of Harrow, Middlesex.

LOCOMOTION IN PARALYSIS.

To the Editor of the Medical Gazette.

SIR,

I APPLIED a few days since, and with the effect anticipated, the following simple arrangement, to facilitate locomotion in paralytic affections of the lower extremities:—

A grooved thin wood wheel, four inches in diameter, and adapted to run in an appropriate *block*, was suspended to a band encircling the neck, and adjusted to correspond to the site of the sternum.

A line corresponding to that of the *sash* having been passed over the wheel, had the one extremity steadily secured above the patella, to a laced cap surrounding the knee of the palsied limb; while the other end was made fast to a convenient handle, so designed as to extend the line when drawn.

The beneficial effect of the process consists in its enabling the paralytic limb to advance naturally, in a right line with the trunk, when the invalid with the sound arm draws the cord at the period of progression; and thus makes his step without exhibiting the rotatory motion of the limb which otherwise takes place.

The shortening of the extremity, which the double flexion of the hip and knee produces, readily explains why the above affords the advantage experienced. Time with practice are both more or less requisite for paralytic people to employ the apparatus usefully.

I am, sir,

Your obedient servant,

JOHN ELDERTON,
Surgeon.

Northampton, Feb. 15, 1837.

PLACENTAL PRESENTATION.

To the Editor of the Medical Gazette.

SIR,

ON perusing the late numbers of your journal, I observed two very interesting cases of placental presentation, treated with success, which remind me of a case almost similar I witnessed in the practice of my relative, Mr. Collier, of Shipston on Stour, Worcestershire, in Octo-

483.—xix.

ber 1833. This gentleman's attendance was requested on the woman, between 30 and 40 years of age, residing about a mile and a half from the above place, who had been in labour for some hours: considerable hæmorrhage had taken place, by which the patient appeared much exhausted.

The pulse was weak, the countenance pale. On examining per vaginam, the placenta was found occupying the whole of that canal, distending it and the os uteri; the fœtus lay across the superior aperture of the pelvis. We decided upon immediate delivery; but, to prevent alarming collapse, wine and other stimuli were placed, ready at hand to be administered, in order to keep up the force of the circulation. This part was assigned to me (keeping my hand constantly upon the pulse, and closely watching its strength—losing no time in giving wine or brandy, when flagging or extremely low); whilst my friend proceeded steadily to perform the operation of turning, and which he succeeded in accomplishing in a short time.

A most favourable circumstance observed, was the proper degree of uterine contraction accompanying the birth of the child: when born, it appeared full-grown, and no doubt had been dead some hours.

The poor woman bore the operation extremely well, and was watched for some hours after. She was visited the four following days; no untoward symptoms occurred; her recovery, I am happy to say, was speedy.

By inserting this communication in your valuable journal, you will oblige,

Sir,

Your obedient servant,

JOHN COLLIER, M.R.C.S.

Brackley, Feb. 21, 1837.

IMMATURE BIRTH.

A LIVING FŒTUS BORN SOON AFTER
FIVE MONTHS.

To the Editor of the Medical Gazette.

SIR,

CASES of the immature fœtus living are so rare, and prove so important in certain medico-legal inquiries, that I make no apology for sending you the following.

3 K

On Friday, the 27th January, 1837, I was called to Mrs. M'Intyre, ætatis 30, a shepherd's wife. According to the woman's own account, she is about five months gone with child, and has felt frequent motion of the foetus during the last fortnight. I found her labouring under a severe attack of bronchitis, which had gone on for some days, and threatened to cause abortion. Notwithstanding the treatment adopted, the violent cough continued, and my patient gave birth to a foetus on the morning of the 30th, at one o'clock. Considering all the circumstances of the case, and the woman's account, I was prepared to find the foetus dead, and was much surprised to hear it cry very distinctly the moment it was expelled from the uterus. The foetal circulation was allowed to go on until a warm bath was prepared for the child, and into this it was put after separation from the mother. It now began to breathe freely while in the bath, and afterwards being rubbed with spirits and wrapped in wool and flannel, was held near the fire. The motions of the extremities were strong and frequent; and a little sugar and water being mixed, it sucked and swallowed with all the instinctive power of a full-grown child. Respiration continued to go on with considerable regularity for three hours and a half, when it died without a struggle on the nurse's knee, having lived from 1 o'clock till half-past 4 A.M.

The following appearances were noted after death:—

The length of the body is $12\frac{1}{2}$ inches; the middle point of the length being at the lower extremity of the sternum; and the weight one pound eight ounces and three-quarters, imperial standard weight. The skin is soft to the feel, and of a purplish tinge, with very little fatty matter beneath. The head round and comparatively small, with a few silky hairs scattered over it. The eyes were unopened, and the external ear complete and of a circular shape. The nails are not apparent. The labia are full, and distinctly separated by a clitoris, large and prominent.

This foetus was probably some weeks older than the mother supposed, but we leave to others, more versant in such matters, to deduce from the particulars given the real age: the father says the exact age of the child is five months and seven days.

The case, as bearing upon the early viability of the foetus, seems not devoid of interest. The writer has seen children born at the full time, in natural labour, who exhibited less vitality, and in whom the respiratory process was carried on with less regularity and completeness than in this case, who yet struggled on to advanced age. It is to be regretted that the extreme coldness of the house, and the want of a proper nurse, with the absence of other "*appliances and means*," gave the little individual no chance of longer surviving.

I am, sir,
Your obedient servant,
J. B. THOMSON.

Alva, Stirlingshire,
Feb. 19, 1837.

TREATMENT OF HYDROCELE BY PUNCTURE.

To the Editor of the Medical Gazette.

SIR,
By inserting the following communication in an early number of the GAZETTE, you will very much oblige,
Your obedient servant,
A CONSTANT READER.

Glasgow, Feb. 24, 1837.

In consequence of the several papers which have of late appeared in the pages of your valuable journal regarding the proposal of treating hydrocele by simple puncture, and the allusion made by Mr. Travers to a similar mode of proceeding with ganglion, which he says has proved perfectly successful when followed by pressure, I was induced to look into the original paper of Dr. Cumin, of Glasgow, on this subject, in the Edinburgh Medical and Surgical Journal for 1825*. That gentleman, after explaining his mode of introducing a cataract needle into the ganglion, freely dividing its sac, and then pressing the contents into the neighbouring tissue, briefly narrates a case in which this mode of practice was successfully pursued.

Dr. Cumin, at the close of his paper, makes the following suggestion:—"It has occurred to me that a similar mode

of operating might be applied to hydrocele, and that a cure of that disease might be accomplished by opening a communication, by means of the cataract needle, between the cavity of the tunica vaginalis and the cellular tissue of the scrotum. No suitable opportunity has presented itself of putting this idea to the test of experiment; but the trial is one which, in the hands of a cautious surgeon, would in all probability effect at least a temporary cure, and which could not be productive of any injurious or unpleasant consequences."

It thus appears that the idea of exposing the fluids of ganglion and of hydrocele to the action of the absorbent vessels of the cellular tissue, and thus effecting their removal, was submitted to the medical profession, in the pages of a widely-circulated journal, about twelve years ago.

MEDICAL GAZETTE.

Saturday, March 4, 1837.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo venendi in publicum sit, dicendi periculum non recuso."

CICERO.

INQUIRY

INTO THE

WORKING OF THE POOR-LAW.

By this time, we suppose, the newly-elected Committee for inquiring into the operation of the present Poor-Law have regularly commenced business.

We mentioned last week that notices of motions for Select Committees of Inquiry were pending in the House of Commons, and that one was for a general investigation into the merits and demerits of the *amended* law, while the other merely sought an examination of the measure as to its alleged efficiency in providing for the wants of the sick poor. It has so happened that neither motion was carried. Lord John Russell, with a *tertium quid* in the shape of an amendment, stepped in and threw his lusty buckler over the Poor-law Commissioners; he would not

allow a hair of their heads to be touched: the law must remain as it is, and the Commissioners are to be held sacred and inviolable. The minor details, however, may be meddled with, and the smaller fry of functionaries may be overhauled, if sufficient proof of their delinquency be forthcoming. The amendment of the Home Secretary, in short, led to the appointment of a Committee, to inquire into the whole working of the act *under* the autocrats who are intrusted with its supreme direction. This was the motion of the honourable member for Berkshire wholly defeated, and that of the member for Finsbury strangled even before birth.

Far be it from us to talk lightly of the defunct, but we cannot help being amused with the source of consolation which the parent of the latter novelty has found for himself. He foresaw its fate last week, rang its passing knell, and then told us very coolly, somewhat in the style of Sir Fretful Plagiary, that he was "rather pleased than otherwise" at what was about to happen. For what—says our legislator—what would have been gained, after all, if my motion were carried?—the Committee would have been granted, the inquiry would have been instituted, the report drawn up and presented; but what would it have been worth? It would be said in the end, that the committee was partial, &c., "and thus, in the minds of many persons, the report would have been set at nought, and the evidence rejected as consisting of materials which had been collected or received by gentlemen whose prejudices unsuited them for conducting an impartial inquiry."

An honest confession, truly! But what are we to think of all this, after the glorification which has gone on for months—the mighty promises made of complete exposure and reform of evils—the self-laudation and advertising, all founded on the notice of a motion which

has been disposed of by a side-wind from Lord John Russell? It is so much the better, says Mr. Wakley, changing his note with the most admirable adroitness—we shall now have a *government* inquiry; mine would have been good for nothing.

We confess we were inclined to give the member for Finsbury some credit for his alacrity in endeavouring to make his promised motion; but it appears now that it was fortunate he was baffled, and that another arrangement has put his wholly out of the way. So says Mr. Wakley, and we suppose we must believe him this time; but let him not blame us for putting only small faith in any of his schemes for the future.

One word more on the funeral speech by anticipation of last week. The member for Finsbury congratulates the medical profession on Lord John Russell's amendment having been carried. Now Mr. Walter's motion was for a thorough inquiry into the whole system of the existing poor-law—its principles and its operation—to investigate the nature of the extraordinary powers committed to a few individuals who have already contrived to render themselves odious throughout the country, by their despotic and cruel severity. Lord John Russell's motion, or amendment, on the other hand, professes to have no objection to any inquiry short of touching on the *principle* of the law, and meddling with the conduct of the despots, its prime movers: the law itself must remain as it is, its operation in minor matters *may* be improved—that is, if it appear to require improvement. Yet this is the result on which the profession is congratulated; at the same time that medical men are informed that it does not signify in the least what may be the general upshot of the inquiry—"inasmuch as *Ministers* will be the authors and regulators of the proceedings," it matters "not one straw as to

the tenor of the report:" only let there be evidence, plenty of medical evidence brought forward, and the evil will work its own cure. Who must not admire this virtuous zeal of the Finsbury patriot? Who does not appreciate the statesman-like view he has taken of the question? Let ministers keep their bill—let them persist in their retrenchment, or starvation, principle, which has rendered the *amended* Poor-law odious and abominable in the sight of every worthy member of society; what cares the patriotic Finsburian?—"not a straw," so as there is a *government* committee, and he in the number of the elect.

For our part we can form any thing but sanguine anticipations of the result of this inquiry. Limited, as it is to be, to exploring defects and grievances, and suggesting remedies, while the *causes* of those grievances, originating in the vile and unnational system which has been introduced amongst us, must be left wholly untouched, what can be expected? And in what way can medical men, who are unhappily trammelled in the system, be benefited, when the degradation under which they labour is part and parcel of that very system which is not to be permitted to be touched?

We should not despair, however. The inquiry will proceed, and its success will depend on the energy of those practitioners who are well informed on the subject, and will not hesitate to bear testimony publicly to the facts with which they are acquainted. The whole profession should be alive to the proceedings which are about to take place, for, be it remembered, they do not concern merely a few medical men living in distant parts of the country, but all indiscriminately, in town and country; the very character of the profession in England, so far as it is involved in that of the mass of its practitioners, is at stake.

A correspondent asks us (page 876), in reference to what we said last week of the propriety of the medical corporations interfering at the present juncture—whether the Colleges and the Hall can do any thing? We certainly think that they *can* do much if they please, and that they *ought* to do their utmost. We do not wonder at the question: for the apathy of those three bodies in regard to all external things relating to the comfort and convenience of their licentiates has long been remarkable: it would seem as if their *precamur tibi omnia fausta* were an eternal adieu, or a piece of advice to the diplomatist to consider how he should henceforth shift for himself, having nothing further to expect from the institution which had just bestowed upon him its honours.

An emergency, perhaps it may be said, has never arisen, of a sufficiently important nature, to call forth the corporate energy of our medical establishments. But that excuse can hardly at present serve their turn; for the principle of the act is spreading,—spreading with a cancerous malignity wherever it can gain access;—the ramifications of the system are protruding themselves every where; nor will the metropolis itself be able to escape them much longer. The consequence will be that a large number of needy, wretchedly remunerated, degraded practitioners, will be found in every quarter, and that a permanent character of a more or less disreputable kind will thus be impressed on the whole profession. The licentiates of the Hall will be reduced beneath the level of the *officiers de santé* in France; and if this be the fate of the great mass of medical men in England, what may we presume will be the destiny of those comparatively few who aim at maintaining a higher rank?

The Colleges and the Hall, then, we say, are imperatively *called upon* to in-

terfere. If it be a part of their mission to support the respectability and dignity of the healing art, now is the time to show that they do not slumber at their posts: now is the time to show that those relations entered into between them and their *alumni*, when certain trials are made and fees disbursed, do not cease for ever.

As corporate bodies, demanding justice for those enrolled on their registers, we are satisfied that our medical institutions, in appealing to the legislature, would produce a powerful effect. We wish we could announce that some step of the kind is likely to be taken, but we regret to say that we can as yet perceive no sign.

How gratifying is it, in the midst of this sluggishness in the higher quarters, to observe the benevolent zeal of a distinguished veteran in the profession; we allude to Dr. Yelloly, of Norwich, who has just made public an excellent letter, addressed to Lord John Russell, “on the arrangements connected with the relief of the sick poor.” In a temperate but firm spirit, he points out to his Lordship the mockery of the *relief* (so called) under the existing Poor-law; the cruelty of the system in relation to paupers requiring medical assistance, and the gross injustice and hardship imposed by it on members of the medical profession. We regret that we have not space to extract largely from Dr. Yelloly’s observations, but we recommend them to the best attention of every medical man.

To the valuable paper of Messrs. Rumsey and Ceeley, in our present number (see page 874), we would also direct attention, affording, as it does, the highest proof of the zeal of these gentlemen in labouring to construct what appears to be an admirably improved plan of medical relief under the Poor-law.

It is gratifying, we repeat, to meet with demonstrations like this, and some others to which we could also refer, showing that there are at least *individuals*, of high feeling and high standing, to whom the character of their profession is dear. Why have we no such demonstration from any of the Corporate bodies? Is it beneath their dignity, beside it, or inconsistent with it? We cannot believe that it is either. Let us therefore observe what passes, and calmly await the event.

LIST OF THE SELECT COMMITTEE

APPOINTED TO CARRY INTO EFFECT THE OBJECTS STATED IN LORD J. RUSSELL'S AMENDMENT.

LORD JOHN RUSSELL, Mr. Walter, (who has declined to act) Mr. Fazakerly, Sir James Graham, Mr. P. Scrope, Mr. Baines, Mr. Hume, Sir T. Freemantle, Mr. Cartwright, Mr. Barneby, Mr. Estcourt, jun., Mr. Ponsonby, Mr. J. Loch, Mr. Wakley, Sir O. Mosley, Mr. Villiers, Mr. R. Gordon, Mr. Miles, Mr. D. Harvey, Mr. Hodges (of Kent), Mr. Chichester (Barustaple).

THE LATE MR. ATKINSON RANSOME.

THIS much respected surgeon died at his residence, Old Trafford, in Stretford, on Friday, the 10th ult. He was born at Norwich, on the 4th of March, 1779. He served his apprenticeship at Lynn, and proceeded afterwards to London, where he continued for some time. He first commenced business in Ipswich, and after residing for a short interval in Bury St. Edmunds, finally removed in 1805, to Manchester, where he was very soon after his arrival, and at about twenty-seven years of age, appointed one of the surgeons to the Infirmary.

Mr. Ransome has been long known as a very experienced and skilful surgeon; and it may be truly observed, that as an operator, in the most delicate and dangerous cases which professional men can have to undertake, few individuals have possessed so high a reputation, or so well deserved it. He commenced at an early period his career

as a lecturer on some departments of his profession. He lectured on surgery in the Pine-street School since 1825, the year after the establishment of that institution; and his clearness, simplicity, and information, combined with much suavity of manners, rendered him a general favourite with the students. He was appointed by his colleagues to deliver, at the commencement of the present session, the general introductory address, a task which he performed in a manner to reflect much credit upon him, in reference particularly to the extent and variety of his intelligence, the liberality of his sentiments, and the practical importance of the instruction and advice which he imparted to the rising members of the profession.

It is well remembered that, on the opening of the Manchester and Liverpool railroad, Mr. Huskisson was killed by an accident. On that occasion Mr. Ransome was immediately sent for; and notwithstanding the fatal result, so ably did he discharge his professional duties, and so highly was that ability estimated, that Mrs. Huskisson presented to him, with expressions of acknowledgment and gratitude, a handsome gold snuff-box.

He was interred on Thursday the 16th, the funeral procession being formed by the members of the medical staff of the infirmary, the lecturers of the Royal School of Medicine and Surgery, and the students of the Pine-street School.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, February 28, 1837.

MR. EARLE, F.R.S., PRESIDENT, IN THE CHAIR.

A PAPER WAS read, on—

“ Long continued contraction of the Lower Extremities, from an affection of the Spine; with observations.” By R. A. STAFFORD, Esq., Surgeon to the St. Marylebone Infirmary.

The author opens his communication with some preliminary remarks upon the influence which the spinal cord possesses in cases of local hysteria, between the various symptoms of which, and those which are produced by acknowledged disease, or injury of the spinal cord, he draws

a close parallel, with the express object of proving that pains, spasms, palsy, or want of muscular effect, muscular contractions of the limbs, and other symptoms, are common both to cases of local hysteria, and to diseases or injuries of the spinal marrow; and accordingly the author infers that both classes of cases have a common origin or cause in a congested or inflamed condition of the spinal cord, or of the roots of the spinal nerves, or of the membranes which invest these parts. And he supports his opinion by shewing that the most successful treatment is that which is directed to allay such congestion or inflammation of the spinal cord, and not that which is employed with a view to relieve the mere local symptoms.

The author illustrates his opinions by numerous examples, and especially quotes four cases, two of which he considers instances of local hysteria, terminating in a contracted state of the limbs, but chiefly of the lower extremities, and to such an extent, that the toes became closely bent on the foot, the foot on the leg, and the leg on the thigh. In both cases the patients were young females.

The other two cases are examples of diseased vertebræ, producing muscular contractions similar to those of the two preceding cases; and, in all four, the symptoms equally arose, in the author's opinion, from a deranged condition of the spinal cord.

In conclusion, Mr. Stafford divides the period of the complaints which are the subject of his paper into three stages:—1st, the acute state, marked by spasms, and pains, more or less severe, in various parts of the body, where he employs antiphlogistics, bleeding, purgatives, &c.; 2dly, the chronic stage, where blisters and other counter-irritants are used; and 3dly, the curative stage, where it is only necessary to restore, by suitable extension, the contracted limbs to their natural position.

At the conclusion of the evening, the President, in an eloquent speech, addressed the meeting upon his retirement from the chair, and took a survey of the progress of the Society during his Presidency, and of its prospects for the future.

Mr. EARLE began by noticing the few resignations and deaths which occurred during the past year. There were but two of the former—three of the latter; and he made honourable mention of the deceased.

Of Dr. HUGH LEY, Mr. Earle said, he had not been long enrolled a Fellow, which might account for his name not having appeared in the Transactions. He was born at Abingdon, in Berkshire, in

the year 1790. He was the son of Dr. Ley, who afterwards practised at Penzance, in Cornwall, where he died in the year 1826. The family of the Leys is of great respectability and antiquity in the west of England, and a branch of it was ennobled in the person of Lord Treasurer Ley, who was created Earl of Marlborough by Charles the First. Dr. Ley, the son, was educated at Abingdon, under the celebrated Dr. Lempriere, and being intended for the medical profession, studied assiduously at the Borough hospitals, and was admitted a Fellow of the Royal College of Surgeons, but afterwards went to Edinburgh, and graduated in the year 1813, having first published an inaugural dissertation, "*De Naturâ intimâ Phthiseos Pulmonalis*," in which he exhibited much research and discrimination. Dr. Ley returned to London about the time of the death of the late Dr. Thynne, who had been Physician to the Westminster Lying-in Hospital, for which appointment Dr. L. became a candidate, and was elected by a large majority, although opposed by Dr. Blegborough, a physician of extensive practice in London. Subsequently to this he became associated with Dr. Merriman, in giving lectures on midwifery and the diseases of women and children, at the Middlesex Hospital, and was appointed assistant physician accoucheur to that institution; and on Dr. Merriman's resignation, he was unanimously elected physician in his stead.

In the MEDICAL GAZETTE there are several valuable communications from the pen of Dr. H. Ley. His only separate publication is an Essay on Laryngismus Stridulus, together with a dissertation on the Pathology of the Nerves, in which he places in a new point of view the nature of an obscure and doubtful disease. It is, indeed, a work abounding with practical information, and demonstrating in every page the acumen and sagacity for which the author was remarkable. But it was in the lecture-room that Dr. Ley shone forth most conspicuously, as few have ever possessed greater powers of language, or greater clearness in the arrangement of his matter. Of him it may be said with truth, "*Erat in verborum splendore elegans, compositione aptus, facultate copiosus.*" Dr. Ley was appointed to the obstetric chair at St. Bartholomew's in the autumn of 1835, and speedily acquired the respect and regard of his class, who will long regret his untimely end. He died of an affection of the heart consequent on acute rheumatism. His professional character was deservedly high, and without blemish; his conduct and sentiments on all subjects were those of a gentleman.

Mr. Earle then gave a short biography of the late Mr. Charles Millard, similar to what has already appeared in our pages. We are obliged to economise our space, and shall therefore pass on to the notice of the late Dr. Henry, of Manchester.

DR. WILLIAM HENRY (said Mr. Earle) is the third and last Fellow whose death I have to announce. He was a graduate of the University of Edinburgh, and was contemporary with Brougham, Jeffrey, and Mackintosh. He was educated to the medical profession, and was appointed Physician to the Manchester Infirmary. The delicate state of his health led him, at an early period, to relinquish the practice of his profession, and to devote himself to the same lucrative pursuits in which his father had been for many years engaged, and to which his taste for chemical research naturally inclined him.

The Transactions of this Society contain three papers from his pen. The first, which was published in the second volume, contains some accurate observations on the chemical properties of diabetic urine. The second, published in the eighth volume, is a short paper on the comparative mortality of measles. The third, which will be found in the tenth volume, is on urinary and other concretions. Dr. Henry is described by those who were intimate with him as having been a most agreeable and instructive companion; possessing great conversational powers; being always anxious to encourage talent, and draw it forth, without any unnecessary display of his own: in a word, he is described as having been the life and ornament of polished society. In all the relations of private life he was exemplary; in his conduct he was open, generous, and sincere. He united with great and successful attention to business an unabated and ardent love of science. He delivered several courses of lectures on chemistry, and published a volume on that science, which passed through many editions, and is equally precise in its information and elegant in style. Besides the papers and works already mentioned, he was a contributor to the Philosophical Transactions, and to the Memoirs of the Literary and Philosophical Society of Manchester. Among his literary productions, his character of Priestley, Davy, and Wollaston, rank deservedly high.

I would gladly pass over in silence the last tragical scene which closed his career, but that it has already become a matter of history; and his biographer has even thought proper to adduce the examples of Brutus, Cato, and Seneca, in extenuation

of the act. As a Christian, I cannot but condemn the sentiments which are expressed in the memoir to which I have alluded. The attempt to palliate a deed committed at a moment when reason had lost her salutary control, by adducing examples of heathen heroism—the cool and deliberate act of minds on which the light of christian revelation had never shone—is, to say the least, equally injudicious and injurious to the memory of the departed. It appears that Dr. Henry had taken a very active part in the proceedings of the British Association, which had been held at Bristol, and returned home in a state of great excitement. For several weeks, “tired nature’s sweet restorer, balmy sleep,” scarcely ever visited his eye-lids: his active mind was kept too constantly on the stretch, and at length gave way; and, in a moment of temporary insanity, he rushed unbidden into the presence of his Maker. “Fuit hoc luctuosum suis—acerbum Patriæ—grave bonis omnibus.”

But let me quit this painful and ungrateful theme, and turn your attention to the more pleasing prospect which the increasing numbers of our associates and rising prosperity of the Society afford. To supply the places of our departed brethren, I have to report that thirty-five new Fellows have been elected during the past year, making, with those elected during the first year that I had the honour of holding this chair, a total of seventy-two members, of whom fifty-eight have enrolled their names, and to whom, with your authority, I have had the gratification of extending the hand of fellowship; to many of whom, from their rank and talent, we may confidently look for upholding the character and extending the sphere of usefulness of this Society. In addition to these seventy-two contributing members, I may add eighteen Honorary Fellows, including some of the brightest ornaments of medical science in various quarters of the globe, and who have all expressed their grateful acceptance of the honour which has been conferred on them.

As might be expected from so large an accession of members, I have much pleasure in being enabled to give a very favourable report of the funds of the Society, which have been not only adequate to the entire ordinary disbursements, and to liquidate some debts and extraordinary expenses which had gradually accumulated, but likewise leave a considerable balance in the hands of our Treasurer: but I will not anticipate further the auditor’s report, which will be laid before you to-morrow.

Gentlemen, there has been considerable delay in the production of the 20th volume

Transactions, which, however, I have the pleasure of presenting to you, have called the attention of the Society to several matters relating to the management, Mr. Earle said, in conclusion—

Gentlemen, I cannot quit this chair without endeavouring to express the high estimate which I entertain of the honour which has been conferred on me in appointing me President during the two past years. I trust that I may, in retrospect, be allowed to hope that the punctuality of my attendance, and the impartiality with which I have endeavoured to conduct the meetings, and to regulate the discussions, has justified you in the election, although I feel that, in many respects, I may have fallen short of my predecessors.

Looking back a careful retrospect of those years, and recalling to my mind the honours, there is but one opinion which I entertain as chairman which has caused me regret, and which I could wish to retract, and it is singular that the paper of the evening should be from the very author on whose former paper I pronounced what I now believe to have been a erroneous opinion.

In my paper on Fractures of the Spine, Mr. AFFORD adduced a case, and produced the patient in this room, with an apparent projection of her first lumbar spine. It, as he supposed, of fracture, but appeared to me to be a case of dislocation of the bodies. I subsequently had a dissection in St. Bartholomew's, in whom a dislocation appeared after death to be a fracture by contre coup, which was the consequence of a fall on the buttocks. In conclusion, I can only assure the author, my gentleman whom I may have differed from by my opinion, that it was at the time I delivered it as much the honest expression of my mind, as my present opinion to him is frank and sincere.

Gentlemen, I shall always consider the appointment to this chair as one of the most honourable which can be conferred on a large body of independent scientists. I am deemed worthy to follow "*haud proterus*," indeed, a Cline, an Abernethy or a Cooper, is in itself most dignified and honourable, but in my case there were other sources of sincere and legitimate gratification. Having succeeded the office of Secretary for seven years and of Treasurer for five, I could not accept the appointment to the office in the Society, as affording satisfactory proof that my previous humble labours for the common weal were appre-

ciated by the Fellows generally. In retiring once more into a private station, to cultivate in common with yourselves the ample fields of medical science, I beg to assure you that I shall at all times consider it my duty to submit to this Society any new facts or opinions which can in any way promote our common objects—the investigation of truth, and the alleviation of human misery. As this Society kindly fostered many of my earlier fruits, I shall not fail to offer for their acceptance those of my maturer judgement; and should the plan which I ventured to suggest last year, of forming Sub-Committees for the investigation of particular subjects, and for clearing up any doubtful or disputed points of practice, be carried into execution, I trust I shall not be found wanting in zeal in aiding, and promoting to the best of my abilities, any inquiry in which it may be supposed that my services can be of any avail.

Gentlemen, once more let me beg you to accept my thanks, and suffer me to express my warmest wishes for the general prosperity of the Society, and for the health, happiness, and success of each individual Fellow.

On Wednesday, March 1st, the Anniversary Meeting took place, when the following officers and members of the Council were elected:—

President.—Richard Bright, M.D. F.R.S.

Vice-Presidents.—Robert Williams, M.D.; Thomas Addison, M.D.; John F. South, Esq.; J. P. Vincent, Esq.

Treasurers.—Samuel Merriman, M.D.; J. M. Arnott, Esq.

Secretaries.—John Clendinning, M.D.; J. G. Perry, Esq.

Librarians.—John Thomson, M.D.; William Coulson, Esq.

Other Members of the Council.—Henry Earle, Esq. F.R.S.; Thos. Nelson, M.D.; J. G. Andrews, Esq.; G. H. Weatherhead, M.D.; Thomas Copeland, Esq. F.R.S.; Richard Pinckard, M.D.; Richard Partridge, Esq.; Henry Lee, M.D.; Joseph Moore, M.D.; Thos. Davis, Esq. (Hampstead).

From the Auditor's report, it appeared that—

	£.	s.	d.
The receipts of last year	679	4	6
amounted to.....			
Expenditure	618	11	3½
Balance in hand	£60	13	2½

The sum total of debts amounting to no more than about 4l.

OBSERVATIONS

ON

THE PRESENT CONDITION OF
MEDICAL RELIEF FOR THE
SICK PAUPERS;WITH RECOMMENDATIONS FOR AN ALTERED
AND IMPROVED SYSTEM.

(For the Medical Gazette.)

A CONSIDERABLE proportion of the general practitioners of medicine in this country are engaged by the Poor-law authorities to supply medical attendance and medicine to the sick paupers. Many practitioners who are not thus employed at present, have been so formerly, or are expecting to be so in future.

The appointment to the medical care of a union, or district, affords the readiest opportunity for obtaining or preserving "private practice" in the locality of such appointment, and thus for securing a means of livelihood.

There is a vast and an increasing number of unemployed young men in the medical profession.

Under the present system, therefore, the majority of medical men are found to submit to any regulations, however degrading to their professional station, and to accept any remuneration, however insufficient in itself to secure the required aid, in order either to preserve their former sphere of practice from encroachment, or to enlarge that sphere, or to procure an advantageous introduction into an entirely new sphere.

It is therefore obvious that the influence, direct and indirect, possessed by the administrators of the Poor-law over the great body of general practitioners, is immense, and if not wisely exercised, must have an injurious effect upon their moral position, and their station in society.

This influence is, however, much increased, by the fact that the professional reputation of the medical officers of unions is at the mercy of the Poor-law Commissioners, and the Boards of Guardians, both of which parties, although destitute of medical knowledge and information, possess the power of deciding as to the proper performance of medical duties, of exculpating any practitioner employed by them from any charges affecting his professional conduct, or of branding him as unskillful in his vocation, or negligent of his duty.

So long, indeed, as the present unlimited powers of appointing and dismissing — of

summoning and judging — of justifying and condemning medical practitioners, continue to be vested in parties necessarily so incompetent, (even although a fairer remuneration for the duties performed were conceded) the medical department of the Poor-law must continue a fruitful source of degradation to the profession — of contention and complaint in every locality — and of suspicion and dissatisfaction, not only towards the Poor-law administration, but towards the government of the country.

It has long been found expedient that medical men employed in the public service should be placed under medical supervision. For this reason, and to remedy the serious evils just noticed, as well as to introduce some uniformity and regularity into the medical arrangements for the sick poor, we recommend that the general superintendence and control of the medical department of the Poor-law administration be entrusted to a medical board, similar to the army and navy medical boards, and composed of persons practically acquainted with medico-parochial duties.

2. The remuneration awarded to union medical officers, is either determined by tender, or is fixed by the Poor-law Commissioners. The first of these modes has the effect of reducing the remuneration (for reasons relating to private practice already mentioned) to a mere nominal amount, and therefore cannot be relied on as a means of ascertaining what is just to the profession, or of insuring proper attendance to the sick poor. It is, besides, universally considered by medical men as disgraceful to them, and is not practised in any other learned profession, nor in the army and navy, nor in any civil office, nor in any liberal occupation; and if introduced into any of these departments, would produce the same dissatisfaction and sense of degradation to the persons employed, and the same inferior performance of duty. The second of the above-named modes is frequently combined with the first; that is, if the "tenders" offered are not considered low enough, the Poor-law Commissioners, or the Boards of Guardians, arbitrarily reduce the amount to their own ideas of adequacy. Thus, neither are medical men allowed to fix their own terms under competition, as has been professed, nor are they permitted to have a voice in deciding what is just to them.

* The present entire absence of any thing like uniformity and regularity in the medical arrangements of the Poor-law Commissioners, may be seen by a reference to the Reports of the several Assistant Poor-law Commissioners, contained in the Appendix to the Second Annual Report of the Central Board.

selves, this decision being entirely committed to the other party in the contract, viz. the Poor-law authorities.

We therefore propose either that the legislature, as a supreme impartial authority, should fix the rate of remuneration; or that this be entrusted to a Board, to whom both parties might confidently look for justice.

If the latter alternative were adopted, and if it were agreed that the Medical Board, already recommended for other purposes, should also exercise this important function, it would be reasonably expected by the medical profession, one member at least of this Board should be appointed by, and responsible to the profession.

3. At present, weekly Medical returns are required to be made to the Board of Guardians, with specifications, not merely as to the names, ages, date of illness, and general state of the pauper patients, which is an unobjectionable regulation, but also as to the nature and designation of the illness, the frequency of medical visits, and even the treatment of the disorder, which latter three particulars must be, for the most part, unintelligible to the parties by whom they are required, and are felt, on this ground, to be inquisitorial by the medical attendants.

While, therefore, the first four particulars continue to be reported to the Boards of Guardians, it is highly important that complete reports of cases under treatment be made to the proposed Medical Board. Such reports would afford evidence of the nature and amount of duty, and the efficiency of its performance; they would also constitute a check against abuses of every description; and if periodically completed and published by the Medical Board, would prove valuable to science, and useful to the public.

4. Under the present system it is a common practice to entrust the care of extensive districts of parishes, and sometimes of entire unions, to individual medical officers. By this arrangement, so detrimental to the sick poor, and so injurious to established practitioners, the Poor-law authorities are enabled to offer "wider fields" for competition, and thus to attract a greater number of unemployed adventurers, and to reduce still farther the rate of remuneration. But however destructive to the interests of the present race of practitioners, and to the safety of sick paupers, such temporary expedients may prove, it is obvious that, ultimately, there can be no other reasonable method of supplying medical aid to the paupers, but by means of the nearest medical residents—men whose ordinary range of practice includes the parish for which a medical officer is required.

We therefore consider it essential that the present arbitrary distribution of the parishes into medical districts be abolished, so that the medical officer be appointed for each district separately.

No surgeon should be permitted to undertake more than a certain amount of parochial duty, nor to act unless possessing certain qualifications as to length of practice, &c. &c.; both which should be regulated by the Medical Board.

If any surgeon, not previously resident or living at a distance, be appointed to the care of a parish or workhouse, the reasons for such appointment should be transmitted to the Medical Board. No election to be valid unless confirmed by the Medical Board. No medical officer should be liable to any investigation of his official conduct, or to be dismissed from office, except by the Medical Board.

Every medical officer should be permitted to resign at any time, upon giving reasonable notice.

5. At present, the relieving officer is permitted to usurp the proper functions of the medical attendant, by deciding on the necessity of medical aid in sickness or accident, and thus to interfere with the effective treatment of the sufferer.

In giving orders for medical relief, the relieving officer is naturally guided only by the desire to retrench immediate expenditure; and, especially where the contract is at a sum per case, he is frequently induced to deny relief to most important ailments in their incipient stages; and thus, with the intention of saving a few shillings at the time, may probably inflict a permanent charge on the rates of some pounds;—not to dwell upon the inhuman neglect and aggravation of disease which such a practice necessarily occasions to the pauper. On the other hand, where the contract is at a fixed sum, this officer feels no check, and therefore generally distributes the orders for medical relief recklessly, without consideration either for the ultimate effects upon the rate-payers or the present loss to the practitioner, and often without visiting at the time, or subsequently, the person for whom he gives the order.

We propose, therefore, that the present practice be entirely discontinued, as affording no security to the rate-payers, no safety to the sick paupers, and no justice to the medical officer; and that the following arrangement be substituted:—

Every sick pauper to apply in the first instance to the medical officer, who should be authorized to relieve him at once, if necessary; and, in that case, to furnish him with a certificate stating that the case required treatment. This certificate should be sent by the patient to the relieving offi-

cer in a specified time after receiving it—say twenty-four hours. The relieving officer should inquire into the circumstances of the patient (if he be not already receiving relief in money or in kind) before the next meeting of the Board of Guardians, and should make a report thereon at that meeting; and thus enable the Board to divide the patients attended into two classes—the one to which the medical relief should be unconditionally given, and the other to which it should be merely afforded by way of loan, the cost being recoverable according to the provisions of the Poor-Law Amendment Act. The Board of Guardians might, of course, if they thought proper, refuse the continuance of the loan of medical relief to such persons. The cost of the relief thus afforded might be calculated at so much *per diem*, with an additional charge for journeys; and should be distinct from any arrangement for the regular paupers.

The result of the whole plan, as sketched out in the foregoing observations, would be, that medical attendance on paupers would be placed under effective superintendence and control; that the just rights of medical practitioners would be protected; that the rates would be secured from expenditure on improper objects; that the sciences of medicine and of vital statistics would be enriched by an extensive and valuable collection of facts; “that the community would have the satisfaction of knowing that the sick paupers would be promptly and efficiently attended by men with local attachments, established practice, and matured experience, affording the surest guarantee for the possession of the many moral and professional requisites for such varied, arduous, and responsible duties.”

NECESSITY OF PETITIONING AGAINST THE POOR-LAW ACT.

To the Editor of the Medical Gazette.

Justum, ac tenacem propositi virum,
Non civium ardor prava jubentium,
Non vultus instantis tyranni
Mente quatit solida.

HOR.

SIR,

I ENTIRELY agree with you, that “if the Poor Law be allowed to continue in its present state, it must entail permanent disgrace and degradation on the profession.”

You have done the utmost to place this clearly before the eyes of the profession from first to last, and I, in common with my brethren at large, sincerely thank you. May your efforts prove successful! I do hope your last appeal will be cordially responded to at least by the great body of practitioners. But can we confidently look to the Colleges or to the Hall? I fear not. Are they impotent, indifferent, or unwilling? What have they done?—Nothing. What can they do?—They say, “Nothing.” Then must we help ourselves.

Well I know the grievous thralldom in which a great number of my brethren are now involved;—well I know the galling slavery many of them are compelled to endure. Deeply I regret that dire necessity dooms so many of them to submit with silent loathing and concealed disgust to worse than Egyptian bondage. Many of them are, indeed, deserving of deep commiseration. But can they expect redress without complaint?—Can they hope for aid without putting *their* shoulders also to the wheel? Let their conduct at this important period justify their claims on the active sympathy of their more fortunate or more independent brethren. To them, indeed, may they *then* confidently appeal.

“If the character of the healing art be in any way dear to us”—if it be desirable to prevent the perpetuation of a most degrading thralldom, the general infliction of a most disgraceful slavery, and the continuance of a most detestable tyranny—let all those who desire to be free, and dare to be honest, manly, and just, speak out—expose the enormities of the present system, especially as regards the medical department—respectfully but earnestly demand redress, and redress must come.

Is it, sir, in the nineteenth century, at a time when every class of the community is so active in acquiring, and so vigilant in maintaining its rights, that an industrious, useful, educated, enlightened, and liberal profession, which is daily conferring on the public unrequited obligations, should allow its just rights to be infringed, and its legitimate privileges to be assailed, by arbitrary and reckless authority, without making timely, adequate, and combined resistance? Have we advanced in science and utility only to retrograde in character and station? God forbid!

Let, then, the Provincial Association, which, to its eternal credit, has accomplished so much, still persevere. Let it arouse its members to a sense of duty and of danger. No time should be lost. Let its councils, in every part of the kingdom, instantly get up petitions to parliament, after the excellent form adopted by the

meeting at Manchester, and again urge on its members the necessity of promptly affording that aid, in the approaching inquiry, which so many have it in their power to bestow. Let every one of us, by petition, or by evidence, to the utmost of his ability heartily co-operate at the present crisis, remembering that while we are asserting the rights and privileges of the profession, we are at the same time supporting the cause of truth, justice, and humanity.—I am, sir,

Your very obedient servant,
A COUNTRY PRACTITIONER,
BUT NO SLAVE.

Feb. 28, 1837.

TREATMENT OF THE INFLUENZA.

REPLY TO MR. SEARLE.

To the Editor of the Medical Gazette.

SIR,

As the treatment of the epidemic catarrh, which still to some extent prevails, is the test by which Mr. Searle wishes his new-fangled doctrine to be tried, I beg, through the medium of your journal, to inform him, that I do not consider that disease to be a criterion by which we ought to judge of the correctness of the views which he entertains respecting the treatment of inflammatory diseases. The inflammation which attends the influenza is very different in its nature from acute, idiopathic pneumonia, or bronchitis. It is modified by the debilitating epidemic disease, of which it is, in fact, merely an effect; and in order to illustrate this point, I may observe, that in typhus fever, inflammation of the brain or of its investing membranes, occasionally takes place at some period of the disease. I have witnessed many cases of this description, and the treatment which I have found to be most successful is to take a little blood from the temples by leeches, or from the nape of the neck by means of cupping-glasses; to shave the scalp,—to cover it with cloths, which ought to be kept constantly wet with cold water; to apply a large blister to the nape of the neck; and to administer antimonials. When this practice, which in some respects differs materially from that which I would recommend in pure encephalitis, is followed, the fever in some cases runs quickly on to a favourable termination,—in others it proves fatal; but in all, the cerebral affection, as every practitioner of experience well knows, is very different in its nature from acute

idiopathic phrenitis. It is not, therefore, the kind of inflammation which we occasionally meet with in such diseases as typhus fever, and the present epidemic, that we are to look for proofs of the soundness of Mr. Searle's doctrine; nor is it to acute idiopathic peritonitis, enteritis, pneumonia, or phrenitis, that we ought to turn our eyes. And I will venture to say, that if a physician, when called on to prescribe for a patient, the symptoms of whose disease are intense headache, wild delirium, red fiery eyes, flushed face, and burning skin, were to prohibit the use of the lancet, which I consider in such cases to be the anchor of hope, and to recommend the "fearless administration of nourishment," he would soon discover that the fruit of such a plan of treatment, in most cases, would be death. And until Mr. Searle can convince me that I should be enabled either more speedily or more certainly to cure such a disease as the one I have just described by his nourishing mode of treatment, I must remain in my unbelief, and continue to oppose the new-fangled doctrine, which I consider to be a kind of an idol which Mr. Searle has set up for himself, and which he has worshipped and adored until he has become so blind as to be unable to perceive its imperfections, even when they are clearly pointed out to him. In this respect, however, he is not singular; for true it certainly is, that in all ages some even of the most distinguished members of the medical profession have also had their idols, before which they have bowed with the same kind of blind enthusiasm; and as I have reason to believe that Mr. Searle is an exceedingly well-informed practitioner, I beg to say that it will afford me much pleasure to continue the present controversy, in the hope that he may either speedily make me a convert, or that I may in the end succeed in dispelling the mist which prevented him, as I at present believe, from perceiving that the new-fangled doctrine which he has promulgated is unsound and dangerous.

I cannot, however, for reasons that need not at present be mentioned, comply with the request which he has made in your journal; indeed, I do not see of what use the avowal of my name possibly can be. My object is "not to cavil," but, if possible, to find out the truth; and I am surely just as likely to succeed in discovering the object of my search by the name of *Investigator* as by any other name. Mr. Searle must, therefore, rest satisfied for the present with the name which I have thought proper to assume; but as soon as my conversion takes place, if destined I am to be converted, I beg to assure him that I shall at once not only inform him

of my real name, and acknowledge the error of my present opinions, but to the utmost of my power assist him in his endeavours to establish the new doctrine,—a doctrine which, notwithstanding all that has been said respecting it, I still consider to be my duty strenuously to oppose.—I have the honour to be, sir,

Your most obedient servant,
INVESTIGATOR.

London, Feb. 20, 1837.

CASE OF SUCCESSFUL CÆSAREAN SECTION.

BY DR. MEYER,
Of Minden.

THIS is the fourth time Dr. Meyer has performed this operation, and three of his cases have terminated favourably. The subject of the following was the wife of a shoemaker, named Holle, residing at Minden, a woman of small size and slender make, aged thirty-eight, who had previously enjoyed good health, and borne three children easily and without any bad consequences. After this she was attacked with an arthritic affection, which, from poverty, privations, grief, and want of timely assistance, had increased to such a degree, that, for the space of a year, she only left her bed occasionally, and was then merely able to crawl about her room, bent double and holding by the chairs.

In this state she became again pregnant; an occurrence, of which the first intimation was given by the motions of the fœtus in utero. On the evening of the 19th of June, labour came on, and towards morning, the midwife in attendance, having discovered an abnormal state of the pelvis, advised her to have the assistance of an accoucheur. A neighbouring physician, Dr. Heilbronn, was called in, who, finding the pelvis so deformed as to render artificial delivery by dismemberment, or the Cæsarean section, unavoidable, ordered the patient to be blooded, and requested Dr. Meyer to take charge of the case.

An examination *per vaginam* showed that the pelvis was excessively deformed. On introducing the finger, which was done with difficulty, owing to a bending inwards of the ossa ilii and pubis, the summit of a round solid body was felt, which at first might be taken for the head of the child, but a more accurate examination proved it to be the distorted promontory of the sacrum, which projected close to the retreating symphysis pubis. Hence it was immediately concluded that the child lay entirely in the false pelvis; a circumstance which also explained the extreme pro-

minence of the belly, which rested with the navel touching the external parts of generation.

Besides that the child was still living, the impossibility of getting at it through the vagina determined Dr. Meyer to abandon at once the idea of dismemberment, and he decided on this plan of operation, which the mother also pressed for; although, from her unfavourable condition, there was little hope of saving her. The further proceedings are thus described by Dr. Meyer:—

“The patient was carried to the table, and placed on a straw mattress. The thighs could be separated only so far as merely to afford room for the hand of an examiner; the lumbar vertebræ appeared to be ankylosed with each other and with the sacrum, and it was impossible to place her in an horizontal posture. In this half-sitting posture, the abdomen presented a space of only about four inches from the umbilicus to the pubes. Notwithstanding this, and the presumption that the placenta lay in the line of the proposed incision, I made choice of it for reasons which seemed to me conclusive.

“Two assistants stood, one on each side of the patient, with large soft sponges, warmed and slightly oiled; while Dr. Heilbronn stood at her feet, ready to hand the instruments and take hold of the child. The abdomen was then firmly and powerfully drawn up, and an incision, about four inches in length, was made through the integuments, commencing as close as possible to the umbilicus, and terminating at the pubes. The division of the linea alba and the peritoneum, to the same extent and in the same direction, gave exit to a considerable quantity of water, showing the coexistence of ascites. The discharge of this fluid, however, diminished the enormous tension of the abdomen, and contributed to facilitate the delivery. In all my former cases I had found the uterus extremely thin, scarcely thicker than stout paper, and easily divided: in the present instance, however, the walls were unusually firm, and three lines in thickness. A new obstacle here arose: in cutting through the uterus, the knife entered the placenta, which was attached exactly opposite the line of incision. The consequences were, a division of the larger vessels which are collected about the centre of the placenta, giving rise to a considerable hæmorrhage, and a further interference with the previously limited space for the introduction of the hand and the passage of the child. No time, however, was to be lost: the section of the anterior wall of the uterus was speedily completed, the necessary detachment of the placenta was accomplished without any excessive hæmorrhage, and

ht knee of the child presented. As evening in the womb was scarcely enough for the passage of the head, necessary to extract the arms; after the head followed, not without some pain, yet without any laceration of the perineum. The extraction of the child was followed instantly by a remarkable contraction of the womb, and the bleeding ceased.

Vomiting came on, accompanied by periodic contractions of the abdominal muscles, so that the assistants were obliged to direct their whole attention to the intestines, which were protruded with force, and which were returned and drawn in with much difficulty by the oiled fingers. When the blood and aqueous humor were removed from the cavity of the uterus, the uterus was soon contracted to the size of two fists; and, as the swollen edges of the incision were tolerably approximated, the external wound was united by suture without further delay. After it was finished, a repetition of the vomiting forced a piece of gum, about two inches long, through the interval between the sutures, two inches from the umbilicus: this was removed with the scissors without any hesitation. Immediately over the pubes an opening was made, about an inch in length, into which a tent of lint was inserted; compresses were placed at each side of the wound, a twelve-tailed bandage applied, and a half an hour from the commencement of the operation, the patient, who during the whole time neither stirred nor uttered a single moan, was laid comfortably in bed; the vomiting had ceased, the cough was less troublesome. The child, a male, came to its full time, and weighed six inches in length, but imperfectly formed, had breathed immediately after birth, cried, and was doing well. About an hour afterwards, during a violent paroxysm of coughing, a full half-ell of air was forced through the opening at the lower end of the wound, and lay between the thighs distended with flatus. The mother, however, unwilling to undo the bandage in the absence of proper assistants, fortunately succeeded in reducing it by the finger, and secured the opening with a compress and strips of adhesive plaster." The child ultimately got quite well.

From the successful termination of this and other cases, Dr. Meyer is led to the conclusion that the Cæsarean section is much less dangerous than is generally supposed; that, when we have recourse to it in time, and under favourable circumstances, it is oftener followed by a happy issue than other violent modes of artificial delivery, adopted in case of great contraction and abnormal formation of the pel-

vis; and that, generally speaking, when there is great probability of saving the mother, it should be preferred to dismembering the living child. Leaving the question undecided, whether the lateral incision should be selected, because the section of the anterior wall of the uterus is likely to meet the placenta, his experience inclines him in all cases to make choice of the linea alba. Finally, he corrects a statement made by him in a paper inserted in Siebold's Journal, 3d Band. 1st Heft, that "in such operations, only one intelligent assistant is necessary;" and declares it to be his conviction, that three intelligent assistants are requisite,—two to prevent the protrusion of the intestines, and a third to remove the placenta and foetus*.

OPERATIONS ON VEINS.

SEVERAL eminent surgeons have lately exercised their ingenuity about certain operations upon the veins, even more than upon the arteries. When the veins become varicosely enlarged, every one knows the serious consequences, and the great difficulty experienced in finding out a mode of treatment at once safe and effectual. It is not admissible for me to enter into a history of what has been done for varicose veins; I can indeed but briefly allude to the most modern proposals. We cannot surely expect much from an electric shock conveyed along the enlarged vessels. Breschet's plan of pinching the veins, whether of the cord or of the extremities, by forceps constructed for the purpose, has frequently answered, and has not been often followed by the severe and dangerous symptoms of phlebitis; I am, however, assured, that repeatedly the parts included in the forceps, not excepting even the vein itself, have sloughed, the ulcer afterwards healing, and all doing well. Sanson has constructed forceps for the same purpose, with the blades so broad, that he keeps the sides of the vein in contact for the extent of nearly an inch; it is said to be not absolutely necessary that the vein should be included between the blades of the instruments, nor that adhesive inflammation should arise; it is sufficient that the vein be compressed so as to stop the course of the blood, when a clot forms, which is subsequently absorbed, leading to obliteration of the cavity of the vessel. The passing of the needles through the varicose vein, after the ingenious manner first practised by Mr. Phillips, of London, for obliteration of the arteries, and for which proposal he has received such

* Neue Zeitschrift für Geburtakunde; and Dublin Journal, Jan. 1837.

honourable distinction in another country, has been recently tried by Lallemand, Davat, and Velpcau. The last of these experienced surgeons has also passed needles beneath the vein, and twisted a ligature circularly or *in-eight* under the projecting ends of each needle, so as to compress the vein. I have myself adopted this plan, and although there was suppuration in the cellular substance, neither general fever nor phlebitis arose, the patient being quickly cured of a troublesome ulcer, and the dilated vein either restored or obliterated.—*Mr. Crosse's Retrospective Address.*

INFANTICIDE BY POISONING.

To the Editor of the Medical Gazette.

SIR,
IN the 22d of Dr. Cummin's excellent lectures on Forensic Medicine, published in your last number, he states it as probable, that there is not a single case on record to show that poisoning has ever been had recourse to as a mode of murdering the new-born infant. Dr. Cummin may be correct in making this statement if he confines his remark to *medical* records; but if he means to be understood generally, as stating that no such case has ever occurred, I apprehend, if my memory does not greatly deceive me, that there exists at least one exception to the truth of his remark. In the records of the Justiciary Court at Glasgow, I think it will be found that such a case did occur some twelve, perhaps, or fourteen years ago. The poisonous substance which was employed on this occasion was the yellow powder called orpiment, or sulphuret of arsenic. Dr. Corkindale, of Glasgow, if applied to, would be able to furnish all the details of the case, as he is always employed by the authorities upon such occasions in that city, his medico-legal knowledge and experience being of a very high order. It is very likely, too, that Dr. Ure's services were required at the trial.—I am, sir,

Your obedient servant,
WILLIAM MACLURE.

LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

By WILLIAM CUMMIN, M.D.

LECTURE XXIII.

Opening of a new division of the Course—Diseases and Injuries medico-legally considered: First, those of the Mind—UN SOUNDNESS OF MIND—Psychology a mixed science, peculiarly adapted to the study of medical men—Legal distinctions and decisions respecting Unsoundness of Mind: 1. In Civil cases—Varying judgments of successive Lord Chancellors—Present arrangement for issuing Commissions; 2. In Criminal cases—Distinction between right and wrong. The different forms of Unsoundness of Mind—Simplification introduced by the French and Germans—Tabular view of the principal forms: 1. Idiocy and its characteristics; 2. Imbecility—How far consistent with a disposing memory and understanding—Remarkable trial in illustration.

With the present lecture I open a new and very important division of the course. We have hitherto considered man either with reference to structure simply, whereby the requisite characters of age, sex, variety, and identity, are determined; or we have contemplated him in regard to the exercise of certain functions, chiefly those of reproduction; but always as in the enjoyment of health. The scene changes, and we shall now proceed to view the human being as the subject of disease or injury which may possibly give rise to questions in courts of justice.

In treating of diseases, we shall have to notice those of the mind as well as of the body; and even give the precedence to the

former, as well for other reasons, as because of their superior medico-legal interest. In the remarks and illustrations which shall presently be offered, proof enough will be adduced of the extreme complexity and difficulty of the subject; nor should you be ignorant that it has proved a quicksand of late years, on which more than one medical reputation has been wrecked.

Medico-legal psychology.—It has been sometimes questioned whether medical men (probably from their being found so frequently at fault) have any title to be considered as essential referees on inquiries respecting soundness and unsoundness of mind,—whether, in fact, they have better means of being well informed on the subject than any other well educated members of society. In Germany the question has been discussed with much energy and heat; some of the disputants maintaining that the tribunals should be guided solely by medical men, others vindicating that prerogative for the pure philosophers of mind. Metzger distinguished himself as one of the chief advocates of the former, Kant of the latter, opinion. But each took an extreme view of the case, and, as often happens, overlooked the truth lying between; neither party was exclusively right, but the preponderance certainly was towards the medical side, and for these reasons:—

1. Because the philosophers are purely theoretical, while medical men study psychology as a mixed science—that is to say, they keep in view the connexion of mind and body. 2. Medical men have by far the best opportunity of personally observing the phenomena of mental disorder. And 3, because in most cases, if not in all, the unsoundness of mind depends on some physical cause. For the thorough investigation of the subject, therefore, the medical man is best qualified by reason of his practical as well as general attainments; and *à fortiori*, when he has made mental disease a principal, or a special study.

UN SOUNDNESS OF MIND.

I use the purely English denomination, unsoundness of mind, as comprehending all the varieties and deviations from the ordinary rational standard which are commonly met with. Like the French *aliénation mentale*, (but with more propriety) it embraces idiocy and imbecility, as well as the various forms of derangement. But as Lord Coke, and some of our highest law authorities, have pronounced the term *non compos*, or *insanæ mentis*, (literally, of unsound mind) to be the most sure and legal, there can be no hesitation in adopting it as the generic term.

Legal distinctions and decisions respecting unsoundness of mind.—What is said in Coke Littleton on the varieties of mental unsoundness is worth quoting in the first instance.

“*Non compos mentis* is of four sorts: 1, *Idiota*, which, from his nativity, by a perpetual infirmity, is *non compos mentis*; 2, He that by sickness, grief, or other accident, wholly loseth his memory and understanding; 3, A lunatic, that hath sometime his understanding, and sometime not, *aliquando gaudet lucidis intervallis*, and therefore he is called *non compos mentis*, so long as he hath not understanding. Lastly, he that by his own vicious act for a time depriveth himself of his memory and understanding, as he that is drunken.”—Coke, Littleton, 247, a.

A person who labours under unsoundness of mind is not contemplated by the laws as other people are: he is not held responsible for his actions. If he possess property, it may be taken out of his hands; at least he may be deprived of the management of it. If he marry, the marriage is not valid; if he make a will, his executors are not bound by it. Again, if such a person commit an act of aggression, or violence, it is not imputed to him as a crime; he is acquitted of the guilt on the ground of insanity.

But the proofs of insanity required in civil and criminal questions are very different; for which reason it will be necessary to consider them separately.

In all cases coming before the tribunals, the question of unsoundness is ultimately determined by the verdict of a jury, and that in most instances turns on the evidence of medical witnesses.

In civil cases.—“An idiot, or natural fool,” says Blackstone, “is one that hath had no understanding from his nativity; and therefore is by law presumed never likely to attain any.” For which reason the custody of him and of his lands is given to the King, by whom it is entrusted to the Lord Chancellor.

In the old common law there is a writ *de idiota inquirendo*, to inquire whether a

man be an idiot or not: which must be tried by a jury of twelve men: and, if they find him *purus idiota*, the profits of his lands and the custody of his person may be granted by the king to some subject, who has interest enough to obtain them.

A man is not an idiot (continues Blackstone), if he hath any glimmering of reason, so that he can tell his parents, his age, or the like common matters. But a man who is born deaf, dumb, and blind, is looked upon by the law as in the same state with an idiot; he being supposed incapable of any understanding, being destitute of those sources by which the human mind is furnished with ideas.

A lunatic, or *non compos mentis*, is one who hath had understanding, but by disease, grief, or other accident, hath lost the use of his reason. A lunatic is indeed properly one that hath lucid intervals: sometimes enjoying his senses, and sometimes not, and that “frequently depending upon the change of the moon.” But under the general name of *non compos mentis* (which sir Edward Coke says is the most legal name) are comprised not only lunatics, but persons under frenzies, or who lose their intellects by disease; those that grow deaf, dumb, and blind, not being born so; or such, in short, as are judged by the Court of Chancery incapable of conducting their own affairs. To these also, as well as idiots, the king is guardian, but to a very different purpose. For the law always imagines, that these accidental misfortunes may be removed; and therefore only constitutes the crown a trustee for the unfortunate persons, to protect their property, and to account to them for all profits received, if they recover, or after their decease to their representatives.

On the first attack of lunacy or other occasional insanity, while there may be hopes of a speedy restitution of reason, it is usual to confine the unhappy persons in private custody under the direction of their nearest friends and relations: and the legislature, to prevent all abuses incident to such private custody, has frequently thought proper to interpose its authority by statutes, particularly 9 Geo. IV. c. 40 and 41, regulating mad-houses. But, when the disorder is grown permanent, and the circumstances of the party will bear such additional expense, it is proper to apply to the royal authority to warrant a lasting confinement.

The method of proving a person *non compos* is very similar to that of proving him an idiot. The lord chancellor, to whom, by special authority from the king, the custody of idiots and lunatics is entrusted, upon petition or information, grants a commission in nature of the writ *de idiota inquirendo*, to inquire into the

party's state of mind; and if he be found *non compos*, he usually commits the care of his person, with a suitable allowance for his maintenance, to some friend, who is then called his committee. However, to prevent sinister practices, the next heir is seldom permitted to be this committee of the person; because it is his interest that the party should die. But it hath been said, there lies not the same objection against his next of kin, provided he be not his heir; for it is his interest to preserve the lunatic's life, in order to increase the personal estate by savings, which he or his family may hereafter be entitled to enjoy. The heir is generally made the manager or committee of the estate, it being clearly his interest by good management to keep it in condition, accountable however to the Court of Chancery, and to the *non compos* himself, if he recover, or otherwise to his administrators*.

But when we come to inquire on what principle the writ *de lunatico* is granted, we find that it depends, for the most part, on the discretion of the Lord Chancellor for the time being. One grants it, as is now usually the practice, in cases of imbecility or weakness of intellect, but another has strenuously refused to consider a case of this kind as coming under the distinction of *insane memorie*.

The following decisions of Lords Hardwicke, Eldon, and Lyndhurst, will exemplify the differences of opinion which have prevailed among eminent judges during the last half century:—"In *ex parte Barnsley*, upon a petition to quash an inquisition, finding the petitioner, from the weakness of his mind, incapable of governing himself, his lands and tenements, the petitioner's counsel observed that there were but two distinctions in law, viz. idiocy and lunacy; and although the latter had been since described by other words, i. e. *non compos mentis*, *insane memorie*, of unsound mind and memory, yet that the words only were changed, and not the law.

"Upon which Lord Hardwicke observed that it was so, and that nothing could change the law therein but an act of parliament. *Non compos mentis*, or, since the proceedings have been in English, 'of unsound mind,' which mean the same thing, are legal terms of a determinate signification, understood by courts of law, importing not weakness of understanding, but a total deprivation of sense. God forbid! continued his lordship, that weakness of mind only, should be a sufficient reason for granting the custody of persons and their estates, for that would take in violent people, drunkards, careless, and silly: and the material part of the traverse is, not to the incapacity of judgment, but to the more material words of unsound mind, or

insane memorie, which all persons must understand to be a depravity of reason, or the want of it; but weakness does not carry that idea along with it, and would be expressed in Latin by *infirmetas mentis*, rather than *insanitas mentis*. In the notion of the old writs, a person must be found either idiot or lunatic; and the courts enlarged the manner of finding, to avoid the difficulty of obliging the jury to find express lunacy, when they might think the case rather that of idiocy. If a man is so weak as to be imposed upon in the execution of a deed by the artifice of another, or spends his money foolishly, or weakly, he does not come within the meaning of the law in cases of this sort; but if men or women, through the weakness of their minds, are drawn in to execute conveyances by fraudulent means, they are relievable in the Court of Chancery; and bills are frequently brought by such persons to avoid their acts, on the ground of fraud. Commissions of lunacy are not intended for such men; their relief is by decree*."

But Lord Eldon, from the same bench, pronounced a very different opinion:—"Of late (says his Lordship) the question has not been, whether the party is absolutely insane; but the court has thought itself authorized to issue the commission, provided it is made out that the party is unable to act with any proper and provident management, liable to be robbed by any one, under *imbecility* of mind, not strictly insanity, but, as to the mischief, calling for as much protection as actual insanity. In the case of Mr. Charles Palmer, he was not insane, but his mind, by years and attention to business, was worn out. Epileptic fits, too, may produce a mind in the same state at a much earlier period. Such cases, therefore, have been thought proper subjects of this writ — *de lunatico inquirendo*. In another recent case, the commission stood upon the same principle. The party, when he could be kept sober, was a very sensible man, but in a constant state of intoxication he was perfectly incapable. No one can look at the present case without seeing that every person about this lady is satisfied that some care should be thrown round her. If clearly it is fit to protect her against executing powers of attorney, that she should not decide where her person, or with what trustees her property ought to be, all agreeing that she should not choose the persons who are to have the care of her property, it is fit for me to put a control upon those who may be proper persons to have the control of her property. I will not subject her now to another commission, but will direct two physicians, who have not been concerned and consulted, to see the evidence, and afterwards

* 1 Blackst. Comm. 302, et seq.

* Collinson on Lunacy, p. 61.

in the most tender manner to find the means of visiting her without alarming her, for the purpose of determining whether her state of mind is competent to the management of her affairs, for this does not seem a case of insanity; and I should think myself bound to do this, if it was only made out that it is not fit she should have the management of her pecuniary affairs*."

We shall now contrast a judgment of Lord Lyndhurst's. After citing the preceding decision, his Lordship proceeds:—"The law, as thus stated, has been acted upon for years; it has been acted upon in the view of the legislature; the legislature has not thought proper to interpose; and we must therefore take the law to be as thus expounded. Yet I think it unsafe that this verdict† should stand. The finding here is similar to what was found in Cranmer's case. There the verdict was, 'that H. C. was so far debilitated in his mind as to be incapable of the general management of his affairs.' What did Lord Erskine say on that occasion? 'How can I tell what is so far debilitated in his mind as not to be equal to the general management of his affairs? Suppose he was a farmer, and his understanding was so far debilitated that he could not manage his farm, though competent to common purposes.' What are the affairs to the management of which he is incompetent? Those affairs may be of such a nature that a certain degree of impairment of memory may render him incompetent to the management of them, and yet he may not be of unsound mind. The inference of the jury—'and consequently he is of unsound mind'—does not satisfy me—it does not follow necessarily from the premises: I cannot, therefore, allow the verdict to stand‡."

It is satisfactory, however, to be able to add, that a recent enactment has put an end to much of the ambiguity which thus prevailed respecting weakness of intellect. The statute 1 Wm. IV. c. 60, relative to trustees and mortgagees, has introduced a power to issue a commission of lunacy in all cases where an individual is "incapable of managing his affairs," although he be neither proved to be an idiot nor lunatic.

In criminal cases.—The law is more precise and determinate in laying down the grounds of responsibility or irresponsibility for crime. The statute 39 and 40 Geo. III. c. 35, enacts, that when, upon the trial of a person charged with treason, murder,

or felony, it shall be given in evidence that the prisoner was insane at the time of the commission of the offence, and such person shall be acquitted, the jury shall be required to find specially whether such person was insane at the time of the commission of the offence, and to declare whether the acquittal has been in consequence of such insanity; and if they so find, the prisoner is to be kept in custody till his majesty's pleasure is known. But in order to prevent the jury from being embarrassed by technicalities respecting the import of the term *insane*, the question which is usually presented to them in all such cases, is, whether at the time the alleged criminal act was committed, the prisoner was *incapable of judging between right and wrong*, and did not then know that he was committing an offence against the law of God and nature?

Thus should it appear that the accused possessed such capability, although the mental delusion might be connected with the crime, and have stimulated him perhaps to commit murder in revenge for an imaginary injury, yet, being shewn to be capable of knowing that he had no right so to revenge himself, he must be held criminally responsible.

The different forms of unsoundness of mind.—The want of definitions and of precise appellations is no where more seriously felt than in treating of the various forms of mental disease. We have seen in the short sketch just given, of the legal distinctions respecting unsoundness of mind, how vaguely the several terms *lunacy*, *unsound memory*, *imbecility*, &c. are employed even by the bench; and it is a general complaint that lawyers take no pains to fix the meaning of expressions which they so commonly use: they seem, indeed, more inclined to secure for themselves a convenient latitude in this respect, so that when they please they may, as it were, play fast-and-loose with the medical witnesses, badgering them (as we too often see them do) to state minutely what is to be understood by such negative denominations as *unsoundness* or *insanity*, when they themselves would with much more propriety endeavour to fix the ideas comprehended under the positive term *soundness* of mind. In the end this probably will be done, and the example has already been set by eminent legal authorities on the continent; but meantime we are not to remain idle, expecting such a consummation: medical men are deeply interested in procuring all the light that can be had on the subject, and from them, no doubt, will be ultimately derived all that information which is requisite to guide and determine the construction of our common and statute law.

Unsoundness of mind, as including every

* 8 Vesey. Ridgeway v. Darwin.

† The verdict was, "that the party was not lunatic, but partly from paralysis, and partly from old age, his memory was so much impaired as to render him incompetent to the management of his affairs, and consequently that he was of unsound mind, and had been so for the term of two years."

‡ 4 Russell Rep. 183.

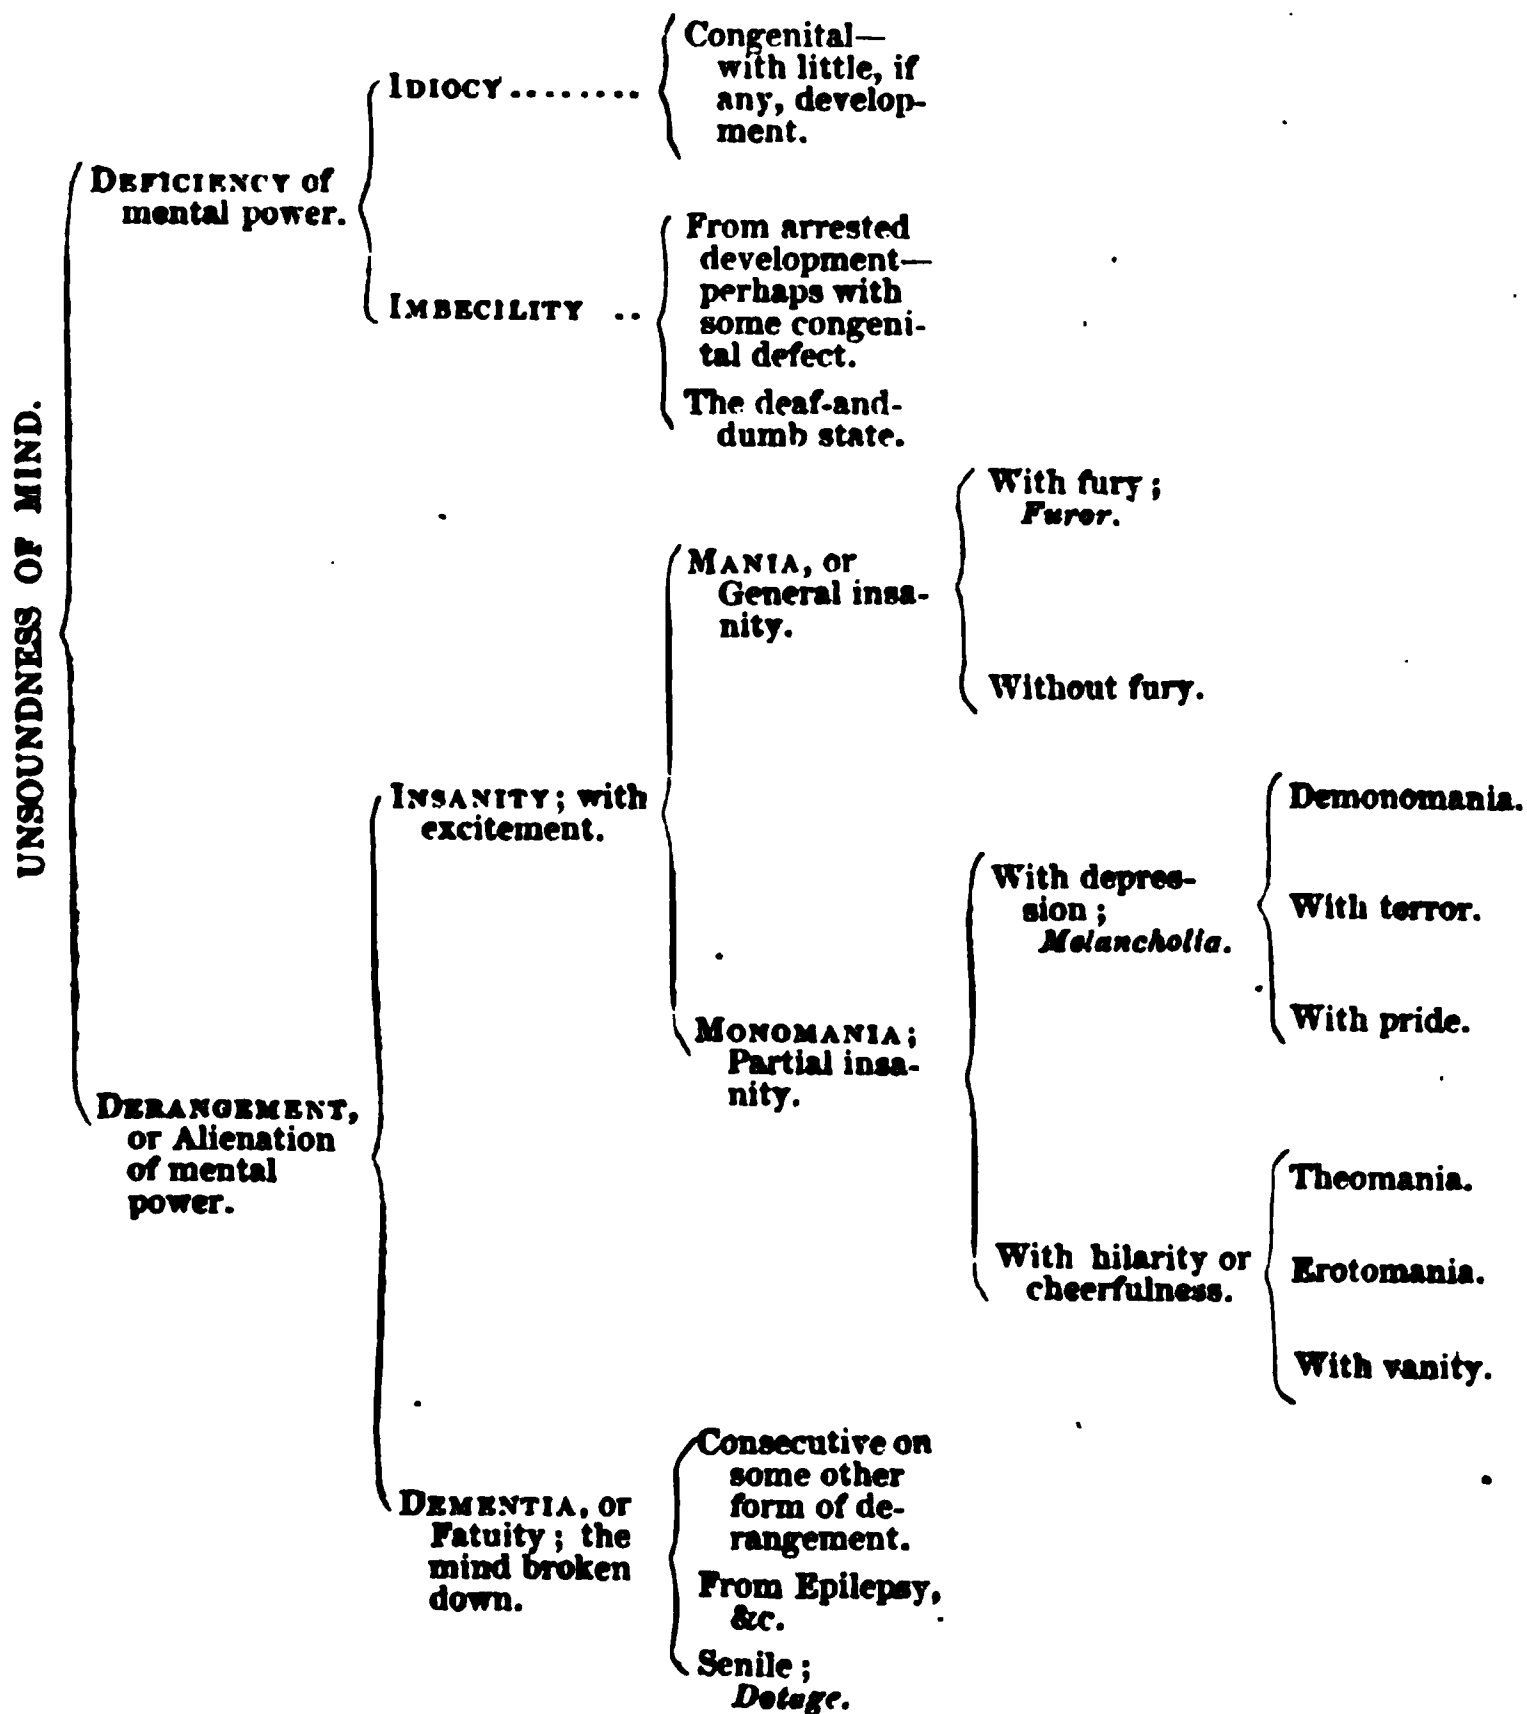

remarkable deviation from the ordinary healthy standard, is obviously a term of wide application; but as in regard to bodily disease we have our classes and orders to refer to, whereby each individual case can be readily recognized, so in determining the nature of particular instances of mental disease, we have an arrangement which seems well adapted to serve our purpose.

To the French and Germans we are much indebted for their psychonological labours; they have simplified a subject which was hitherto all chaos; they have supplied us with a nomenclature at once adequate and perspicuous; and they have already, we may say, so far displaced the old system of confusion, that in treating henceforth of mental disorders it will be possible for authors to be generally intelligible, with-

out using terms in senses peculiar to themselves. Only a few years since, it was necessary, in proceeding to peruse the remarks of any English writer on insanity, to settle in the first instance in what sense he employed his terms; for it was sure to be different from that of any one else even of his contemporaries: but of late a uniformity has begun to prevail, which cannot but be attended with the most beneficial results.

Medical jurists ought to be well acquainted with the prominent characteristics of the several forms of mental unsoundness. I shall here offer a sketch which will be found useful in appreciating the features of the leading varieties; but first let me call your attention to this table, which exhibits at a glance the relations of the different forms to each other:—

TABULAR VIEW
OF THE
PRINCIPAL FORMS OF UNSOUNDNESS OF MIND.

This arrangement explains itself. Unsoundness of mind, the generic term employed as "the most safe and legal," is in the first instance considered as consisting either in deficiency or derangement—the mind having never attained, or having departed from, the ordinary sound state. Deficiency of mind is then divided according as it arises from congenital imperfection, or from some obstacle supervening which permits only of a partial development. We have thus the two forms of idiocy and imbecility.

In derangement, the mind may be looked upon either as morbidly excited, or as having its powers abated: hence we arrive at the several forms of mania, monomania, and the different kinds of dementia. Mania, again, is distinguished according as it is attended with fury or not; and monomania, as it exhibits a depressed condition or the reverse.

Of some of these varieties it will be necessary to offer a more detailed description, and particularly of the following five—namely, idiocy, imbecility, mania, monomania, and dementia. By making ourselves familiar with their characters, we shall find our task of distinguishing and classifying particular cases submitted to us, will be materially facilitated.

Idiocy—its characteristics.—Absolute idiocy, for it admits of some slight degrees, is always connected with more or less of personal deformity or disease. The head is generally remarkable for its disproportion to the stature—sometimes extremely small, with retreating and narrow forehead, sometimes voluminous, with obtuse facial angle; the features are heavy, often hideously ugly; the eyes meaningless; the smile stupid. The body is mostly short and ill-shaped, very thin, or very fat. In regard to mental power, the little portion of mind which the idiot possesses is almost a perfect blank; there is no understanding, no faculty of articulate speech, a few parrot-like words probably are the utmost that can be uttered. The will is in similar abeyance, no emotions, no desires, scarcely even an instinct. Where the idiocy is not so thoroughly deplorable, there are some slight glimmerings of ideas of sense, and of feelings of pleasure and pain; sometimes even a trace of gratitude towards a kind keeper may be observed.

Cases of this description can scarcely give any difficulty to the medical jurist; being congenital, and their history known, there is commonly no mystery about them. It might so happen, however, that in some isolated instance an attempt at imposture might be made: not that a person who had already been known to enjoy reason could well put on this form of unsoundness—for it were a clumsy character to assume—the broken down mind, such as his should be, displaying the linaments of

dementia, not those of idiocy: but some wandering impostor might endeavour to play the arrant fool for some mischievous purpose. Where there is reason for suspicion of this kind, seclusion and secret watching of the party would soon afford evidence of his real state.

Imbecility.—This is a state of mind which often affords ample room for discussion and litigation. The imbecile possesses only a limited portion of mental power: his intellectual and moral development has proceeded only to a certain extent—some bodily disorder then probably interfering, or his original stock of mind being capable of cultivation no further. Some, however, are capable of a considerable degree of intelligence,—may be taught certain mechanical trades; some can even learn to write, or to read, and perhaps may be made to comprehend the rudiments of arithmetic. But almost every thing they do is performed in a slovenly, unfinished manner. They are destitute of a reasonable degree of attention; their memory is accordingly very imperfect, and their powers of comparison and association most limited.

We often observe marked shades of variety in the imbecile: a propensity to music and mimicry is sometimes displayed; and while some are extremely peaceable and orderly, others are cunning—given to theft, and sometimes carried away even to acts of assassination. Their passions are frequently violent and unmanageable: grief also, and the appearance of strong religious feeling, have been noticed among their characteristics.

The great difficulty attending these cases in medico-legal practice is to trace out the limits whereby persons of this class are distinguished from others who are competent to regulate their social and moral conduct. In criminal trials there is reason to believe that imbeciles have often (not so often, however, in this country as on the continent) been found guilty, where they were really not responsible; and in civil suits, the decision of the validity of acts done by the imbecile has sometimes turned on points perhaps scarcely comprehensible by the jury themselves who pronounced the verdict.

An example of the latter kind is afforded by a remarkable trial which took place not long ago on the Western Circuit. It was an action to set aside a will made by a young woman (Frances Smith) of weak mind: the heir at law was plaintiff, the legatee (Ann Smart) defendant. Counsel on either side admitted that there was imbecility in the case; but the question was whether it existed to such an extent as to incapacitate for making a will,—whether, in fact, the testatrix possessed a "disposing memory," so as to be able to bequeath her property with understand-

ing and reason. Much evidence was adduced on both sides, for it was necessary to inquire into the whole tenor of her life: a witness was produced who was present at her birth, and various others testified to her habits during her girlhood and married state.

Frances, or Fanny Smith was a farmer's daughter; her head was misshapen at birth, owing to some injury received during delivery; and she very early exhibited signs of inferior intellect; she required assistance in all the common affairs of life, was uncleanly in her person, and very simple minded. Her proper station seemed to be in the farm-yard, where it appears she often used to work hard with her mother. Many of the farm labourers and rustics gave a pretty fair account of her understanding, according to their ideas of sound mind; but the Rev. Mr. Benson, the clergyman who celebrated her marriage, while he considered her capable of entering into the married state, and even of disposing of her property, admitted that her appearance induced him to think she was weak in her intellect, and "a very weak person."

The evidence of the solicitor who drew her will and attested a previous execution of a mortgage deed, was strongly in favour of her "disposing" capacity; but he went so far as to say that there was nothing even in her countenance to indicate weakness of mind. Dr. Grove, too, a physician who saw her relative to an insurance on her life, thought she was competent to make a will; but he stated in his certificate that she had a degree of eccentricity of mind, though nothing approaching to anxiety.

On the other hand, in addition to abundant testimony regarding the slovenly, uncleanly, childish, and unmeaning habits of the testatrix, it was proved that at school, where she was sent at the age of 10, she had not the capacity of a child of five,—she could scarcely be taught any thing: it was impossible to teach her to sew—yet she learned to write a little.

Mr. W. H. Coates, surgeon, of Salisbury, gave evidence to this effect:—"I attended Fanny Smith at times, from 1819 till her death, during which period my attention was drawn to her mind. No one could attempt to converse with her without seeing that she was imbecile in a low degree. I gave a certificate in 1828 and 1829, after I had considered the state of her mind: those certificates state she is very nearly an idiot. I examined her a third time, with Dr. Finch, at my house. I put questions to her. We first wished to ascertain whether she understood the nature of disposing of property, but we could not discover that she did. I

put down a few figures which a child of six years could sum up, but she could not do it. She was incapable of doing simple addition. I should say she was incapable of any important transaction. She did not appear agitated or confused. She continued in the same state to the time of her death. I performed an operation on her breast; I then remarked that she expressed no sensation of pain, and at her confinement she did not exhibit the same feelings as other persons. There was a defect of sensibility, which frequently accompanies a defect of mind.

"Cross-examined.—Women suffer pain better than men. She scarcely made answers to any of our questions. I think those she did give were not rational. She possessed some mind, but of a very inferior description.

"Re-examined.—She had not a mind to protect herself from fraud. I put the ordinary tests to ascertain the state of her mind."

Dr. Finch was next examined.

"I am a physician, and have kept a lunatic asylum for thirty years. I attended with Mr. Coates, and the certificate describes my opinion.

"Cross-examined.—An idiot can have no idea of numbers, or of the value of money."

The trial lasted four days. In his address to the jury the learned judge (Mr. Baron Gurney) commented at considerable length on the evidence "The law," he said, "had been correctly stated, that it was not requisite on one side, in support of the will, that it should be made out that the person was an idiot; and it was stated on the other side, that it was not requisite to establish that the person was of superior understanding, or even of the average understanding of mankind. But there must be mind, there must be memory, there must be judgment; and it was for them to say, upon the examination of all this evidence, whether this woman, Frances Smith, had a disposing mind, memory, and understanding. The case was one of the most extraordinary nature, for the evidence on one side and the other was most completely at variance; the one placing her understanding perhaps higher than it ought to be, and the other putting it possibly lower than it ought to be; but it was confessed that she was a person of very weak mind, and they were to say to what extent that weakness went, whether it was that degree of weakness which incapacitated her from the disposal of her property by will; and there was this remarkable observation to be made, that the greater part of the witnesses in the lower class of life, in support of the will, stated that she had no weakness at all. On the

other hand, the witnesses against the will placed her low, very low indeed. They had to contrast this; and it was for them to decide which was correct."

The jury, after a short consultation, returned a verdict for the *defendant*—that is to say, for the validity of the will*.

CASE OF
OBSTRUCTED URETER;

WITH ULCERATION OF THE KIDNEY AND
ABSCESS.

BY ROBERT ALLAN, ESQ.

Staff Assistant Surgeon.

JOHN GOURLAY, private in the detachment 29th Regiment, stationed at Black River, aged 30; a native of Stirling (N.B.), of robust constitution, nine years in the tropics, and addicted to the free use of ardent spirits; went to bed in his usual good health on the evening of the 4th October, 1835, and awoke about three o'clock in the morning, complaining of violent pain, increased on pressure, in the site of the descending colon. Pulse 104, full; skin moist; thirst. He voided small quantities of urine, highly tinged with blood, every few minutes.

Venesection ad lbij. Fomentat. abdom. frequenter. Hab. Ol. Ricini, ℥j.

The blood was bled and cupped; and about noon the pulse fell to 98. Having vomited the castor oil, a stimulating enema was thrown up. The pain ceased, and he slept two hours; it, however, returned at intervals during the day, while the abdomen became tumid, and tender on pressure. He slept several hours in the following night, but on the morning of the 6th suffered more severe abdominal pain, with the pulse 100, very full; skin hot and dry; less blood in the urine.

Rep. Venesection ad lbij. Hab. Sulph. Magnesiae, ℥j; et injec. Enema Cathartic.

The bleeding produced syncope, and the cathartic operated twice. In the evening the pain shifted towards the left loin, and the pulse was 106, feeble.

Hab. Hanst. Anodyn.

He passed a sleepless night; and on the 7th the pain was very severe about the sigmoid flexure of the colon. He obtained relief by bending the body forwards. Ardor urinae; urine very bloody. Pulse 114, weak; bowels slow.

Descend. Baln. Tepid., et hab. Sulph. Mag. cum Carbon. Magnes.

In coming out of the bath he voided, per urethram, a triangular piece of gravel, the size of a split pea, after which he felt much easier, and slept a few hours. Pulse rose to 120, and the cathartic operated. He now complained of pain in the left testicle. In the afternoon the urine was voided perfectly clear, and without pain. Pulse 100.

During the two following days the pulse remained about 100. He had a few slight attacks of abdominal pain; urine natural. Warm baths, and frequent doses of nitrous æther, were administered.

On the evening of the 9th the pain returned suddenly, and with great violence, in the course of left ureter, extending to the testicle and orifice of the urethra, while no change of position brought the slightest relief. There was cold clammy perspiration, and tumid abdomen; urine clear, and in moderate quantity. The pain and fever diminished in a few hours.

From the above date a swelling was observable in the left iliac region, which daily increased, and the discharge of urine diminished. The bowels required to be frequently stimulated. He continued to pass sleepless nights, and there was great anxiety, while the pain in the tumor sometimes increased considerably. The stomach became irritable, and his strength declined rapidly. Emollient poultices were applied to the tumor, and opiates nightly administered.

On the 30th the tumor was very prominent at the left linea semilunaris, and there was a prickling pain; pulse 96, soft; urine of natural colour, but voided in small quantities.

Taking into consideration the extent of the swelling, which threatened to burst into the abdomen, the many sleepless nights and consequent exhaustion, it was advisable that an attempt should be made to give exit to the contents of the tumor without delay; and Dr. Stewart (assistant-inspector of hospitals)

* An excellent report of this trial may be found in the *Times* newspaper of March 16, 1835.

having arrived from head-quarters, on the 31st October the following operation was performed:—

The skin, cellular membrane, and abdominal muscles, were divided to the extent of an inch and a half, in the direction of the fibres of the internal oblique, and about two inches distant from the crest of the ilium, in the line of the umbilicus, and on the iliac side of the apex of the tumor, with the view of keeping clear of the peritoneal cavity. The fascia transversalis appearing tense, a large trocar and canula were thrust through it; the trocar being withdrawn as the canula was pushed in. Seven pints of urine flowed out, all of which, with the exception of the last few ounces, which were gelatinous, and evidently the exudation from an inflamed surface, was perfectly clear. An elastic-gum tube was introduced, and the canula withdrawn; adhesive straps, compress, and bandage, applied.

In a few hours after the operation he complained of uneasiness in the wound, caused by the point of the tube; the pulse rose to 120, and he voided some clear urine by the urethra. The severe pain and tension were completely removed, and he slept the greater part of the following night.

On the third day after the operation, the elastic-gum tube was withdrawn, as nothing had passed by it. He voided urine in small quantities frequently, and with burning pain; pulse 120, and abdomen rather tense.

On the 3d November he vomited repeatedly, and the abdomen was much swollen. Pulse 122, very feeble.

Hab. Mist. Camphor. frequenter.

On the 4th there was constant vomiting and hiccough, while the swelling in the iliac region was as great as before the operation. The trocar and canula were again introduced through the wound, and six pints of clear urine came away, which was followed by the slow discharge of two pints of well-formed pus. An elastic-gum tube was retained in the wound.

The report on the evening of the 4th, states, that "a considerable quantity of clear fluid and pus came along the tube, at frequent intervals, during the day; vomiting ceased, and he slept a little; pulse 120."

Emaciation and debility increased

rapidly; he had no appetite; the discharge of urine from the wound averaged two pints and a half, with one of pus, in the twenty-four hours,—while the urine by urethra amounted to a pint. Bowels required to be kept open by laxatives.

On the 13th November a large elastic-gum catheter was passed by the wound eleven inches and a half, and retained there a few minutes.

The appetite improved, and, owing to the emaciation and great discharge of pus, his diet was increased. He now had chicken soup, two eggs, and a pint of porter, daily, and took sulphate of quinine with sulphuric acid.

At this time he was in an extreme state of debility, and had an ulcer on the sacrum from pressure; pulse 120, but he slept tolerably well.

About the middle of December the quantity of pus began to diminish,—the appetite continued to improve, and his mind became easy.

Anxious to ascertain if the ureter was pervious (for it was imagined that the opening led into it), an elastic-gum catheter was again introduced by the wound eleven inches, and a pint of milk and water injected with considerable force, none of which entered the bladder, but flowed back by the side of the instrument.

A gradual and very visible improvement was going on in his general health, and about the end of December he was able to sit up an hour daily.

There were several symptoms of stone in the bladder, such as ardor urinæ, and great pain at the meatus urinarius while voiding the last drops of urine, along with a mucous deposit. He was sounded; the instrument gave great pain in passing the prostatic portion of urethra, but no stone could be felt.

In January he remained out of bed two hours daily, and was able to walk about the room; appetite continued good, and the pus from the wound did not exceed four ounces in the twenty-four hours. Sometimes very little urine came by the wound, while the quantity per urethram was increased; for instance, it is reported on the 9th January, that "only three ounces of urine, with four of pus, flowed by the wound, and six pints of pale urine by urethra, during the last twenty-four hours; pulse 114; thirst; bowels regular. The elastic-gum tube is still in the wound."

On February the 11th, it is noted that "he sleeps well; pulse 128, feeble; thirst; skin hot and dry; appetite very bad; has not been gaining strength for some time past; feet œdematous. From two to three ounces of pus discharged by the wound daily."

Towards the end of February he suffered a smart attack of dysentery, but under the use of blue pill with opium, and small doses of castor oil, the severe symptoms subsided in a few days.

Emaciation and debility again increased; appetite fell off; he had griping, tenesmus, and vomiting. The urinary affection underwent no change, but he was so weak that he could not sit up even in bed. On 8th and 9th of April he voided a quantity of mucopurulent matter by stool; on the two following days the stools were yellow and thin. He sank rapidly, and died on the evening of the 11th.

Post-mortem examination.—Body much emaciated; no disease in the head.

Chest.—Both lungs attached to the pleura costalis by old adhesions.

Abdomen.—Peritoneum natural, except over the left kidney and lumbar muscles, where it was of a dark blue colour. This kidney, which was enlarged to twice its ordinary size, adhered strongly to the surrounding parts; its tubular portion was destroyed, or converted into little cells, having a common communication with the pelvis of this organ, and opening besides, by ulceration in the cortical substance at two points, into a sac capable of containing a pint, occupying the cellular membrane in the lumbar region. The mucous lining of the kidney was thickened by inflammation, and the commencement of the ureter similarly changed in structure, and completely closed at this point by coagulable lymph, while in the remainder of its course it was contracted, but pervious. An elastic bougie inserted by the external wound, after taking a direct course for two inches centred in close contact with the outer surface of the peritoneum, turned up into the abscess behind the kidney. Right kidney of ordinary size, but paler than usual; its ureter natural.

Bladder small; mucous coat inflamed; and two superficial ulcerations near the fundus.

Mucous membrane of descending co-

lon and rectum slightly inflamed, softened, and covered with pus.

There are several points in this case worthy of remark, and a few of which it will be difficult to give a satisfactory explanation. The sudden attack, and bloody urine from the commencement, until he voided per urethram a small calculus on the third day. There can be little doubt that the passage of this stone caused the pain and hæmorrhage; and the symptoms which supervened would have led us to imagine that the ureter was blocked up, either by another calculus or coagulable lymph, but the appearances on dissection fully prove it was the latter which caused all the disturbance which followed. He had no pain in the loins during the first eighteen days, although the tumor was very manifest between the false ribs and crest of the ilium on the 5th; at this time the urine was probably contained in the kidney, and the consequent inflammation terminating in abscess behind that organ, may account for the pain becoming acute in the lumbar region after such a lapse of time*.

The patient lived five months and eleven days after the operation, without any great degree of suffering, and might have existed for years with a urinary fistula, if the continued discharge of pus and the dysenteric affection, coming on when in a debilitated state, had not exhausted him.

Port Louis, Mauritius,
June 14, 1836.

CASE OF
LEPRA AND PSORIASIS,
TREATED
WITH SULPHUR FUMIGATIONS.

To the Editor of the Medical Gazette.

SIR,

WITH some hope of reclaiming for fumigatory baths that justice which is indis-

* Dessault observes, "ces depôts ne se manifestent au dehors que lorsqu'il s'est fait dans les cavités du rein une crevasse par laquelle l'urine et le pus se sont épanchés dans le tissu cellulaire, et y ont formé un nouveau foyer qui a usé ou détruit en partie les muscles abdominaux. Alors il n'est pas rare de voir paraître dans les lombes, entre les fausses côtes et le rebord de l'os des isles, une tumeur circonscrite plus ou moins volumineuse."—*Traité de maladies des reins urinaires.*

putably their due, I send you briefly the treatment and results of an obstinate case of skin malady lately under my care.

The subject, a lady aged about 24 or 25, had been afflicted for upwards of nine years. The limbs and body were covered with leprous round spots, from the size of a crown to that of a shilling, with raised red edges, depressed in the centres, and covered with scales. In some parts were large patches of psoriasis, irregular in shape and at the edges, not depressed in the centre, but surmounted by thick scales. The face, and palms of the hands and feet, were the only parts of the body exempt from the disease. The general health had always been remarkably good, save a proneness occasionally to severe headaches. This long-standing disease had come on in the first instance without any appreciable cause, but underwent some diminution in degree during the summer months. The skin was unperspirable and stiff with this encasement, but the itching by no means so distressing as in those assailed with prurigonous diseases—that is, those of the order papulæ, exanthemata, &c. &c. The health, as previously stated, was good; she was quite a stranger to functional derangement, or stomach complaint. I particularize the latter, as that organ has so often to bear the onus of being the cause, or at least the cause of the continuance, of many of these complaints; whilst on the contrary, in cases of lepra and psoriasis, I have commonly found the stomach in an enviable degree free from dyspeptic ailment. This I know to be at variance with the recorded opinions of most, if not all, writers on the diseases of the skin.

After this statement, an apology may seem needful for the medicines that were ordered in this case, in conjunction with the fumigating baths. In short they were ordered *empirically*, in the hopes that they might occasion or assist in effecting that change or alteration in the system which in the end might prove beneficial to the patient. The lady commenced by taking half a dozen simple vapour-baths, with the view of softening the surface, lessening the tension, and detaching the scales; and this was effected. She then took a usual purgative dose, and the next day commenced with the sulphur fumigation, and the following medicines:—

R Liq. Hydrarg. Oxymuriat. ℥ij.; Potassæ Hydriod. gr. xxxij.; Spt. Cinnam. ℥j.; Aquæ Distill. ℥v. M. sumat cochl. magnum, mane nocteque.

The fumigations were taken, almost without interruption, one daily for six weeks, the time the lady remained under my care; and to the patches of psoriasis, and the most unyielding of the leprous spots, she used an ointment composed of one drachm of the hydriodate of potass to an ounce of grease, applied night and morning. I omit dates in this detail, as needless, occasioning prolixity, and occupying more space than you can allow.

At the end of six weeks the lady returned to the country, greatly amended; and, on her arrival at home, was to leave off the medicine and application, and substitute for them the following:—

R Liq. Arsenical. gtt. xviii.; Liq. Potassæ, ℥j.; Spt. Cinnam. ℥a.; Infus. Aurantii, ℥viiss. M. sumat partem sextam bis die. Pil. Hydr. Submur. gr. v. omni nocte sumenda.

The dose of the arsenic to be gradually increased under proper guidance, and for the former ointment the following was substituted:—

R Hydrarg. Oxymuriat. ℥ij. pulv. substit. levegat. Vit. Ovi No. iij. Mist. Cæræ. ℥ij. M. To be used night and morning.

She was directed to adhere to the last prescription for a month, and then to leave it off and resume the former; thus alternating the medicines and applications, and which, I think, is often attended with advantage. At the end of two months I received the following letter from the parent of the young lady:—

“Sir,—The time having elapsed that you mentioned before you wished to hear from me, I now have great satisfaction in saying that your baths and treatment of my daughter's complaint have even exceeded our most sanguine expectations, and if it continues, will equal our greatest wishes. The spots have almost totally disappeared, leaving at present a little redness behind, which no doubt time will wear away. When I look back on the length of time she has had the spots, and the total failure of so many eminent medical men's attempts to remove them, I must confess I came to you certainly expecting some relief, but not with the most distant

hopes of a cure being effected; and I shall ever feel thankful that we came to London. She took the medicines as directed, and often uses the Jekyll steam bath, and finds it an invaluable comfort. The skin has peeled off, she thinks, two or three times," &c. &c. *

I do not send you this brief detail as embracing any thing novel in the complaint, but rather to show that by the properly-regulated administration of the sulphur fumigations, a commonly intractable form of disease may be made to yield in comparatively a short time, but which, under ordinary circumstances, will resist the most judicious means of treatment for a lengthened period, as in this lady's case.

When the sulphur, or other fumigations, are not well advised or well managed, they as often do no good; and by setting up a febrile state of the system, are frequently mischievous in their effects,—disappointing alike the patient and the medical adviser. Yet the fault rests not with the fumigations, but mostly with the adviser, in not duly preparing the patient for their use, or in the case being one for which at first the fumigations are too stimulating,—in short, inadmissible; and the latter I very often find to be the case.

These means are commonly advocated for diseases of the skin generally speaking; yet disappointment in the results will always follow in cases of eczema and prurigo, when proper treatment, as rest, mild diet, and perhaps bleeding or purging, has not been previously resorted to; and I do not hesitate to say, that for the successful treatment of various diseases by the fumigatory method, a practical knowledge of its effects, and of the best way of managing the apparatus, is as needful as a due knowledge of diseases and their remedies in any other cases where the art or science of medicine is called in aid.

Unquestionably it is a powerful therapeutic agent; and when any such means are misapplied, we ought not to be surprised if our own errors lead us to disappointment. I am led to these remarks in hopes that, through the influence of your excellent and widely circulating journal, they may tend to disabuse the fumigatory treatment from the ill report that now attends it, and

which is spreading in this country; and which, if not rectified by medical practitioners themselves making it a subject of more consideration and interest to them, these excellent means of relief, not only for maladies of the skin, but for a great majority of other chronic complaints, will certainly be brought undeservedly into disrepute in England. How shall we, then, appear to our continental neighbours, opposed to this *methodus medendi*; whilst each succeeding year has shewn more and more the increasing estimation in which these remedial means are held in the treatment of diseases? Witness the astounding number of upwards of one hundred and eighty thousand of these baths, which have been administered annually at the Hospital of St. Louis alone, during the last three years; and the precision, discrimination, and order, with which they are administered, shew that the treatment after this method has become part of a regular system of therapeia.

What are we to expect, then, but disappointment, if not discredit, if any person, however deficient in the necessary knowledge, shall be allowed to assume to advise, and to administer, fumigating baths, and those baths improperly constructed, and mal-managed? Yet such is the case here; and at present I know but of one redeeming circumstance that tends to check this growing evil, and by which its otherwise baneful tendency is abated, viz. the knowledge, the constant care and attention; and, not the least circumstance, the expenses which are necessarily attendant upon the conducting of a correct fumigatory establishment, are such as to stamp with an almost certainty of failure every employment of the remedy where these essentials are wanting. And I cannot help expressing my conviction, that it is the duty of every medical man who recommends the employment of a powerful therapeutical agent, to assure himself that the agent is correct, and properly administered; and so protect his own reputation by shielding his patient from the consequences of its improper application.

I am, sir,

Your obedient servant,

JONATHAN GREEN.

40, Great Marlborough-Street,
March 6, 1837.

* Dr. Green has forwarded to us the original letter.—ED. GAZ.

STRICTURES ON CERTAIN PHRASES
AND CONFLICTING OPINIONS,
IN LAENNEC'S CELEBRATED WORK.

To the Editor of the Medical Gazette.

SIR,

I PURPOSE, in the following paper, to make a few passing remarks on the work of Laennec, but without entering into many of those nice and difficult questions concerning which the most experienced auscultators frequently hold different opinions.

By placing together, under the eye of the student, some quotations remarkable for their extravagance, he will perhaps be more strongly impressed with the necessity of exercising a reasonable scepticism on this subject in general, than he would be by reading them separately. Those which contain contradictory opinions are naturally calculated to produce the same effect.

These considerations may serve in some degree as an excuse for the great proportion of Laennec's remarks introduced into this article. Had I contented myself with merely referring to them, there is little probability of their having been looked into so far as regards my present object.

They may serve, too, as a starting-point for future observations, more especially if any injudicious admirer of Laennec should attempt to defend him, or to follow his example in these respects. If some of the assertions contained in his work had not so utterly bid defiance to every thing like moderation, the task of criticism might have been an easier one; but what can be said in refutation of statements which might almost remind one of the extravagances of romance?

If I speak strongly on this subject, it is because I feel strongly, and know too well the great evil which may result from the manner in which auscultation has been presented by Laennec, not to mention many others who have assisted in injuring a really good cause, by putting forth exaggerated pretensions in its favour.

Introduction.

"Some of the signs given by mediate auscultation are very easily perceived (*très faciles à saisir*), and it is sufficient to have heard them once in order to

recognize them ever afterwards. Of this kind are those that indicate ulcers of the lungs, great hypertrophy of the heart, fistulous communication between the pleura and the bronchi, &c.

Further on he says, "It is sufficient to have watched a disease two or three times to learn to recognize it with certainty; and the greater part of the affections of the lungs and heart are so common, that after having sought for them for a week (*pendant huit jours*) in an hospital, there will only remain a few rare cases to be studied, which, with few exceptions, will be met with in the course of a year if almost all the patients are examined with attention."

He admits that a medical man entirely devoted to private practice cannot be expected to follow an hospital for so long a time, but suggests that the physician should inform his "*confrères*" when he meets with any rare or interesting case. "In this way any practitioner may learn in a short time to recognize with certainty, not only the cases mentioned above, but also peripneumonia, pleuritis, latent catarrhs,—*the least rudiments of these affections.*"

Can the English language supply terms sufficiently strong to characterize the extravagance of the greater part of the preceding assertions?

De l'Inspection des Parois de la Poitrine.

On this subject the expressions of Laennec seem to have been strongly influenced by his own invention and highly valuable discoveries. With regard to phthisis in particular, the flattening of the upper part of the chest corresponding to the disease, and more especially, perhaps, the heaving of the shoulders, and the dragging up instead of the expansive motion of the ribs, ought seldom to leave much doubt as to its nature. After some attention to these points, the diagnosis may frequently be made with little difficulty, even through the ordinary clothing of the patient, especially when the shoulders are thrown back.

CHAP. II.—*On Percussion.*

It must be recollected that Laennec had in view *immediate* percussion. His remarks are excellent, although leaning to the side of severity. We shall hereafter see, that upon particular occasions he viewed this subject in a more fa-

vourable light, and seemed almost to forget that "practice, dexterity, and great attention, are requisite for obtaining accurate results by percussion" (*la percussion ne donne de résultats exacts qu'autant que l'on y apporte de l'habitude, de la dextérité, et une grande attention.*)

De l'Auscultation de la respiration.

After stating that in persons whose lungs are very healthy the respiratory sound is sometimes very weak, or almost inaudible, and mentioning some of the circumstances in which this occurs, Laennec advises that in these and all other cases where that sound is very feeble, the patient should be made to cough, in order to produce a full inspiration; the same result being sometimes obtained by making him speak or read, and especially recite, some phrases consecutively.

These directions are very proper; but in attempting to act upon them, it will often be found difficult to make patients either cough, or speak, or read, or recite, in such a way as to produce an inspiration fitted for the object in view.

After giving some rules for exploring the respiration, he adds—"All these precautions, however, are only necessary for beginners. In a month or two the ear becomes accustomed to distinguish, amidst the sounds that reach it at the same time, that particular one of which it is in search, and to hear it in some degree exclusively, even when it is weaker than all the others."

I suspect that few can justly boast of such success as this.

"When the respiration is heard distinctly, and with nearly equal strength, in all parts of the chest, we may affirm that there is neither effusion in the pleura, nor *engorgement* of any kind in the pulmonary tissue.

"When, on the contrary, the respiration is inaudible over a certain extent, it may be affirmed that the corresponding part of the lung has, from some cause, become impervious. This sign is as well marked, and as easily perceived (*aussi caractérisé et aussi facile à saisir*) as the existence or absence of sound distinguished by percussion, according to Aveubrunner's method, and it indicates precisely the same thing."

The manner in which percussion is spoken of in this last sentence will no doubt restore the spirits of those who

might have been somewhat discouraged by reading the chapter on that subject. If we now turn to the *Section troisième—Des productions accidentelles développées dans le Poumon*, we shall find something scarcely reconcilable with one of the preceding remarks.

"When any tumor is of rather considerable size—that of an egg, for example, the stethoscope indicates its presence by the absence of respiration in that part. But when the tumors are small, *however numerous they may be*, auscultation affords not the slightest indications (*l'auscultation n'indique plus rien*), if the pulmonary tissue between them is otherwise healthy.

"I have often heard respiration effected with equal force and clearness (*avec une force et une netteté égales*), on both sides, in individuals who, when opened, presented one lung in a healthy state, or containing only some tubercles of very small volume, and the other filled with tumors of the same kind, varying in size from a millet seed to a filbert, and so numerous, that this lung was at least doubled in weight."

But to return to "*l'auscultation de la respiration*,"—respiration cavernous. Of this I shall content myself with saying that a long course of study will be found requisite for attaining such a degree of skill as shall justify a decided opinion about it in general; nor will even this exempt any one from the necessity of great caution in many instances.

As to the remark, that, in cases of doubt, other phenomena afforded by the voice or cough speedily remove all uncertainty, it would have more value if the voice and cough were not themselves of most difficult interpretation.

De l'égophonie.

Let the student recollect, that, according to Laennec, *égophonie* cannot be fully relied upon as a sign, unless it consists in a bleating, shrill, and silvery resonance, at the surface of the lung. (*l'égophonie n'est vraie et sûr comme signe que quand elle consiste dans une résonance chevrotante légère et argentine à la surface du poumon.*) and he will not lightly pronounce as to its presence.

Such an *égophonie* is, I apprehend, of rare occurrence; and perhaps Laennec has rather limited than too much extended the powers of auscultation in

this instance. There are superficial "frémissements," scarcely accompanied by the other characters mentioned, which appear to be sufficient proofs of the existence of liquid in the pleura.

De l'Auscultation de la Toux.

To distinguish the resonance of the cough in a large bronchus from its resonance in a cavern, is, in many cases, a most difficult task, and the attempt too often serves to lead into doubt or error.

When a timid patient coughs only from the throat, without producing any resonance in the bronchi, the remedy proposed is to invite him to take a deep inspiration, and then to cough.

On a former occasion we were taught to make a patient cough, in order to produce an inspiration; and now we must make him take a deep inspiration, in order to reach the cough. It happens rather unfortunately that these difficulties generally occur in the same individuals.

De l'Auscultation du Râle en général.

Speaking of a sort of "léger frémissement," which each species of râle imparts to the cylinder, whenever the point where the râle takes place is situated under that to which the cylinder is applied, he says, among other things, that when the râle exists ("à son siège") in a part distant from the point where the cylinder is applied, although it may be heard distinctly, and even strongly, the "frémissement" in question cannot be perceived; and that when it cannot be perceived on any point of the surface of the chest, the "râle" is situated in the most central parts of the lung.

"This sign may, in the reading, appear to be a refinement (subtil à la lecture); but I can affirm that nothing is more easily perceived (que rien n'est plus facile à saisir), and that some minutes' study are scarcely necessary for learning to distinguish, with the help of the stethoscope, the distance of the point where the râle is produced (le degré d'éloignement du point où le râle a lieu)."

To criticize an assertion which no one will probably be so unwise as to defend, might seem an useless task.

De la Dilatation des Bronches.

When the dilatations occupy the

ordinary situation of tubercular caverns, auscultation may be a source of error. When, however, they are confined to the lower and middle portions of the lungs, without caverns or dilatations in the upper, auscultation may throw much light upon the nature of the disease.

Signes physiques de la Pleurésie aiguë.

It is scarcely necessary to prove that one of the most valuable signs of the presence of liquid in the pleura is a variation in the sound from percussion, accompanying a change of posture in the patient, and which variation is well explained by the situations occupied by the lung, and the liquid in those different postures. That a satisfactory result cannot always be obtained by this means, either from the patient's debility, his unwillingness to facilitate the inquiry, or from other circumstances, is very true, but notwithstanding these exceptions, this sign is deserving of the utmost attention. Corvisart, in his commentaries on the work of Avenbrugger, has spoken with decided approbation of this means of diagnosis, and has described his own mode of employing it. Laennec, who has quoted Corvisart on several other occasions, contents himself here with saying, that he had seen "quelques médecins" try to obtain a distinguishing sign between pleuritis and peripneumonia, by placing the patient in different positions, and that he had made the experiment himself, without obtaining any satisfactory result. This, I will venture to affirm, was not the fault of the method, which is frequently applicable even in cases where the quantity of fluid is very considerable. Adhesions may destroy its value, or the contrary, according to their extent and situation.

In the article, however, "Des signes et des symptômes du Pneumothorax," the skill of Corvisart in percussion, and his failing to recognise the disease by its means, are not forgotten.

"Here I shall merely remark, that during my attendance on the instructions of Corvisart (pendant que je suivais les leçons de Corvisart), I witnessed the opening of many subjects affected with pneumothorax, in none of whom had the disease been suspected."

"The talent for observation of this celebrated professor, and his skill in

profiting by percussion (*à tirer parti de la percussion*), will not be denied by any one ; and consequently the best proof of the insufficiency of that method for revealing the existence of pneumothorax, is the circumstance of its not having been recognized in those cases."

Exploration des organes de la Circulation.

"The application of the hand, the sole means of exploration before Avenbrugger, seldom gives any result, and frequently leads into error as to the real force of the heart's impulse."

I apprehend that the force of the heart's impulse can be as well judged of in general by the hand as by the stethoscope, whilst the former gives a sensation of the volume of the heart as a whole, and of the left ventricle in particular, much more accurate, perhaps, than the latter.

That gradual heaving, so characteristic in many instances of a large and powerful left ventricle, can be felt at a given time over a greater space by the hand than by the stethoscope*.

The different "*bruissements*," whether in the heart or arteries, have been the source of much ingenious speculation. With regard to the disturbance of the currents of blood by diseased valves, disproportioned outlets, projections into the arteries, &c., as a cause of these "*bruissements*," one consideration rather embarrasses me. On looking up the aorta, there may be seen at a moderate distance from the heart, three openings (to the *arteria innominata*, left carotid and subclavian arteries), with edges apparently calculated to produce whirls and eddies every time the blood is sent from the left ventricle with any degree of force, and yet "*bruissements*" are only occasional there, as well as at other divisions of the arteries. This objection may, however, have been already made and refuted, without my being at present aware of it.

EDWIN HARRISON.

Grove-Terrace, Lisson Grove,

* For a practical conviction of the valuable information to be derived from applying the hand to the cardiac region, and also from attending to the mode of respiration in phthisis, I am indebted to Dr. Chambers.

DISCOVERY OF CILIARY MOTIONS IN THE CAVITIES OF THE BRAIN.

BY PURKINJE.

I HAVE succeeded at last in discovering the *Ciliæ* and their motions in the ventricles of the brain in the mammalia. Last summer, while examining the *Chordæ Bergmanni*, I perceived, on fine sections of the epithelium, a structure resembling the ciliary membranes, and suspected that this epithelium possessed a similar function. I thereupon made numerous investigations with this object in view, but without any result until the 23d of May, when I succeeded in discovering the ciliary motions in a state of the most beautiful activity, on the edge of the *Tenia Hippocampi*, in the tolerably mature foetus of a sheep thirty hours after slaughter. They now appeared quite distinct over all the windings of the ventricles, and they could be plainly distinguished, even where they did not appear in motion. I followed the motions, without difficulty, through the third ventricle to the infundibulum, to the olfactory tubercles, and finally through the aqueduct of Silvius into the fourth ventricle. Here the motion ceased, but the *ciliæ* were still distinctly observable, although somewhat shorter than in the foregoing situations.

The *ciliæ* are proportionably long, pointed (not ragged, as in the bronchial tubes), and exhibit a whip-like vibration; we perceive also a layer of granules to which they are attached, and which are very easily rubbed off without destroying the continuity of the epithelium. The other day I examined the brain of a sheep, in which they could also be perceived with great facility. They have been seen likewise by Dr. Valentin, in the tolerably matured foetus of a sow; in another foetus of the same description, at a much earlier period, they could not be distinguished: probably the parts are too delicate for our clumsy instruments. On the whole, I have perceived from these few examinations, that the *ciliæ* found in the ventricles of the brain possess a finer degree of sensibility, and are much more easily destroyed, than those of any other organ. I have not been able to discover them in the brain of a sparrow, or of a carp, which I examined; but cannot, on this account, draw any con-

clusions as to their non-existence. I could not detect any traces of them in a deceased human brain which was sent me: probably they are very transient, (as appears to be ascertained from the female ovary, and the mucous membrane of the nose), but as easily reproducible. I could not find any ciliæ in the membrane of the choroid plexus; but I have made long since a very interesting observation on this membrane. The whole plexus is covered by a peculiar matter, like the granular substance of the ganglions, and composed of the most regular granules, each of which contains a small corpuscle in its centre. This membrane appeared to me at the time as belonging to the nervous tissues, although at present I see many reasons to look upon it as epidermal *.

•

CASE OF
HYPERENCEPHALOUS MONSTROSITY;

CONJOINED WITH OTHER MONSTROUS
FORMATIONS.

—

To the Editor of the Medical Gazette.

SIR,

THE following abnormal conformations were met with lately in a dead-born foetus of the 7th month, the product of a first pregnancy in a young married female.

The cranial bones were deficient above plane of occipital protuberance, so that a great part of occipital bone, the whole nearly of both parietals, and almost the whole of frontal bone, were wanting. Beyond the margins of these bones a large nodulated cerebral mass protruded, covered with a smooth, fibrous-like membrane, of a dark red colour, continuous with the scalp. The inside of this firm membrane presented a villous or pulpy appearance, with cord-like bands running along it in different directions. Through the interstices of these bands the brain formed several encephalic swellings, giving it, as above stated, a nodulated appearance. One of these encephalocèles, situated where the posterior fontanelle ought to have been, was nearly

the size of a small hen's egg, formed by the protrusion of a considerable part of right posterior cerebral lobe. In its centre a clot of blood of considerable size was found. At the summit of middle lobes of cerebrum there were two other smaller protuberances, of a flattened form. The one on right side was larger of the two, and attached to its base there was a portion of membrane in every respect resembling the foetal envelopès, forming a sort of open, elongated pouch. This membranous pouch in structure bore no resemblance to the membrane investing brain, nor did it present the characters of common false membrane, but seemed really part of the foetal membranes, with which we presume the brain had, at this part, during an early period of intra-uterine life, become united.

Two or three additional small encephalic swellings were observed above and behind ears, and one about the size of a nut, at lower part of middle of forehead.

The substance of brain was very soft and congested, containing a few small bloody extravasations, in addition to the one above-mentioned. Its convolutions were not very distinct. It was fully larger than is commonly found in a well-formed foetus of the same age. It appeared low and narrow anteriorly. The base and central parts were well developed, and the nerves sent off from it well formed and regular.

Cerebellum, as to size, natural, but covered with a thin layer of coagulated blood. Bones forming base of cranium perfect, as also spinal column.

The face, which was of a brownish red colour, presented a very unnatural appearance. The eyes were wide apart, and prominent. In place of the usual conformation of nose, there were two small roundish apertures, corresponding to nostrils, sufficiently large to admit the point of a common quill, through which the spongy bones were visible. These apertures were about half an inch apart, and from each of them a fissure, or groove, between three and four lines in width, passed obliquely upwards and outwards, running close to inner canthi of eyes, and terminating about half an inch above superciliary ridges. These grooves were lined with mucous membrane, continuous with that lining inter-

* Dublin Journal, March 1837.

nal nares. Superiorly they became gradually more superficial, till lost in the adjacent skin. A narrow bridle of skin was stretched obliquely across the upper part of the one on right side.

The right side of upper lip was cleft in same line as corresponding groove in cheek, and the traces of consolidation of a similar division on left side were visible; the line of junction being slightly depressed and irregular.

The ossa nasi and nasal cartilages were defective. The other bones of the face were well developed, and the constituent parts of superior maxillary bones firmly united. There was a fissure in fore-part of hard palate, not extending through the bone. Its edges were thick and slightly everted.

The abdominal parietes, from inferior extremity of sternum to the insertion of umbilical cord, were patent, and eversion of liver, stomach, with the spleen and intestines, existed. The liver was large, and somewhat different in shape from what it usually is. It extended from upper part of right side of chest, obliquely downwards, to the left of umbilical cord, with a deep notch in its inferior extremity, into which umbilical vein entered. It was slightly attached to diaphragm at its posterior surface. The other abdominal viscera presented nothing worthy of particular notice.

The ribs on right side, in place of arching forwards to be articulated with sternum, were bent downwards, forming a very acute angle with the vertebræ, reaching to the spine of ilium. The upper ones were slightly twisted upon themselves. From the unusual direction of ribs the pericardium immediately came into view, on the integuments being raised from front of chest. Heart normal. Two-thirds of right side of sternum defective.

Right superior extremity was wanting. On dissection, we found the clavicle in a rudimentary state, balanced between the sterno-mastoid and subclavius muscles. There was no scapula; but a little below distal extremity of clavicle, lying on lateral aspect of two of the upper ribs, a small cartilaginous body, of irregular form, was found, to which the trapezius, rhomboides, and serratus magnus, were attached. The latissimus dorsi and pectorales muscles were wanting. The cervical nerves

on this side were scarcely perceptible filaments.

The *arteria innominata*, as usual, divided into two branches. The carotid coursed up the neck as usual, but the other branch, corresponding to the subclavian, after giving off the inferior thyroideal, passed upwards and outwards under internal jugular vein, and entered the transverse processes of the vertebræ, at points where the vertebral usually enters. No branches corresponding to the transversalis colli, internal mammary, or supra-scapular arteries, were given off from the above artery, before entering the vertebræ to ascend to the encephalon. At its origin it was nearly as large as the carotid.

We may state that the placenta presented no pathological lesions, and the labour was natural.

Although several irregularities of organic formation are not unfrequently conjoined in the same subject, it is not often, we believe, that such a combination as the above is met with. The monstrosities which the face exhibited are of rare occurrence. Klein and Nicati were the first who particularly noticed them; they have since been described by M. Larocbe under the title of congenital fissures of the cheeks. According to M. Isid. St. Hilaire, they arise "du défaut de soudure ou de la soudure très-tardive de deux des cinq pièces principales, qui, d'après MM. Serres et Beclard, composent la machoire supérieure chez l'embryon, comme le bec-de-lievre depend du défaut de soudure ou de la soudure très tardive de l'inter-maxillaire et du maxillaire*." Like hare-lip, these fissures or grooves may be simple or double, and vary in extent. They are seldom observed extending so high as in our case.

Much light has of late been thrown on the laws which regulate the production of monsters. Meckel, St. Hilaire, Serres, and others, have shown that arrested, retarded, and excessive development of the various organs, are sufficient to account for a large proportion of these irregular beings; but as it would be out of place to enlarge on this subject, we may be allowed to state, that the hypertrophy of the brain probably originated from the increased

* *Traité de Tératologie*, t. i. p. 502.

quantity of blood sent to it through the subclavian artery, which, as has already been stated, took the usual course of the vertebral, and that, by the teratological law of antagonism, or "balancement," the cranium was correspondingly atrophied. St. Hilaire is of opinion that adhesions between the ovum and its envelopes are occasionally the cause of congenital deformations; and those of the head in our case might partly be dependent on this cause. Nicati has described a monster, which, like ours, was affected with fissure of the cheeks and hare-lip, and in which the umbilical cord, after its exit from the abdomen, was rolled round the head, and connected with a prolongation on top of head, which he supposed to be a branch of the umbilical cord, but which was probably merely something analogous to what was met with in our case. On Nicati's case St. Hilaire makes the following remarks:—"On peut supposer avec beaucoup de fondement, comme l'a fait mon pere, que la pretendue branche cranienne du cordon ombilical était un simple cordon tegumentaire établi entre le placenta et la region de la tête qui presentait le vice de conformation; en d'autres termes, une de ces brides d'adherence que l'on voit si souvent etendues entre les parties frappées d'anomalies et le placenta ou les membranes de l'œuf, et qui, par le tirage qu'elles ont pu exercer sur ces parties, auraient mis obstacle à leur developpement regulier *."

The absence of the upper extremity is satisfactorily accounted for by the deviation of the subclavian artery, and so far supports M. Serres' opinion, that all organic deviations result from irregularity or deficiency of the vascular system,—an opinion supported by many strong arguments, but not altogether free from objections.

The foetus above described is now in the possession of my friend Mr. J. Douglas.—I remain, sir,

Your obedient servant,
WALTER DICK.

"Licet omnibus, licet etiam mihi, dignitatem Artis Medicæ tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

PARLIAMENTARY INQUIRY

INTO THE

WORKING OF THE POOR-LAW.

SEVERAL letters have been sent us, during the last week, on the subject of the medical arrangements under the present Poor-Law: we publish a selection from them which we think will be found interesting, and to which, we have no doubt, a high degree of importance would be attached were we at liberty to disclose the writers' names.

The "Retired Practitioner" may be excused on the score of his position for not being aware of our having anticipated him on some of his topics: it is satisfactory, however, to find him recommending the very same kind of expedients that we have proposed—particularly with reference to the propriety of the corporate bodies interfering in behalf of their licentiates and alumni. The members of the corporations have the same opportunity of knowing, in their corporate as in their individual capacity, the grievances by which the great mass of the profession in the provinces are oppressed—while their means of being useful are certainly not the more circumscribed by belonging to those institutions which originate the different orders of practitioners. "Chirurgus," indeed, who is manifestly in the councils of "his order," informs us that the College of Surgeons has interfered, but ineffectually. Does it follow, however, from this, that they set the right way to work? Were the steps of their procedure prudent and well advised? Have they yet presented any

* Loc. cit. p. 593.

petition to parliament, praying for a redress of those abuses and grievances to which their licentiates are so notoriously exposed? Society rings with the complaints made of the mode in which the Poor-Law functionaries have mismanaged the medical part of the system: their "tendering" and intimidations, their threats, insults, and degrading treatment of medical practitioners, are every where talked of. Now it appears to us that the corporate bodies, if they have any doubt as to the facts, ought to inquire into them,—the occasion justifies almost any departure from old rules: and should they in the course of their researches obtain, as we have no doubt they would, the amplest confirmation of the hardships and indignities suffered by men undeserving of such treatment—men who hold *their* diploma, and who are in great measure reduced to such extremities by being thus connected with an overstocked profession—we repeat, that those bodies are bound to intercede, with all discretion certainly, but without bating a jot of firmness or determination to have justice.

Important, however, as it is, that the medical corporations should take a leading part in asserting the rights of the profession, it must mainly depend on the general body of practitioners throughout the kingdom to crown the object with success. As our correspondent, who subscribes himself "Personally unaffected," recommends, petitions should be got up in every town and village where there are medical men: the appeal for justice should be made to both Lords and Commons: no apathy should be displayed in an hour so critical. Facts and evidence should be forthcoming; the views of individual practitioners, who have bestowed time and attention on the consideration of the subject, should be submitted to

parliamentary cognizance; and above all, where plans for adjusting the complicated difficulties of the question have been devised, they should be laid before the legislature without the loss of a moment. It is well known that what is everybody's business is nobody's business, and that unless some two or three persons consult together, to perform that which it is the interest of the community to see accomplished, the work will always remain undone.

Luckily this disposition to shift off one's own shoulders the business of meditating and acting for the common good does not universally prevail amongst us. We were last week enabled to point out some exemplary instances of the contrary.

In our last number we published the observations of the Messrs. Rumsey and Mr. Ceeley, regarding an improved plan of medical relief for sick paupers. These gentlemen, with most commendable zeal, have deeply reflected on the difficulties embarrassing the present system, and have arrived at some expedients which seem well adapted to remove impediments. Their demonstration of the necessity of a Medical Board, on the plan of those directing the medical concerns of the army and navy, is conclusive; and their strictures towards the abolition of the "tender" and lowest possible remuneration system, have much force. But our readers, we trust, have perused the document for themselves; our reason for at present noticing it is to draw attention to an Appendix since published by the same authors. During the week, the Observations, together with the Appendix to which we allude, have been presented to the public in a pamphlet shape; we may therefore complete our edition by at least some account of the additions, regretting that our space will not allow us to give them more at length.

The first paper in the Appendix is from the pen of Mr. Robert Ceeley, of Aylesbury, in which the author proposes, as a sort of fundamental principle, that medicines and medical attendance for paupers should not be supplied from the same source.

"Medicines, leeches, and other appliances, should be purchased at the joint expense of all the parishes of a Union, be deposited in an appropriate place, in a Dispensary, in a convenient part thereof, and be put under the care of a proper person (a Dispenser), who should dispense the same according to the directions only of the several medical officers of the Union.

"Each distant parish should have a sufficient supply of medicines, preparations, &c. for ordinary use, deposited in an appropriate place, for the wants of the paupers of that parish, and under the care and direction of the parish medical officer.

"In all urgent cases, sick paupers would thus be spared the trouble, time, and delay of sending to a distance for medicine; other cases not so urgent might, if necessary, be dispensed for at convenience, at the central Dispensary. Thus the delay in the administration of important remedies would be prevented, and all temptation to withhold suitable medicines, or the *suspicion thereof*, would be completely removed."

With regard to the fitting remuneration for medical attendance—a most difficult and complicated problem—Mr. Ceeley lays down a scale which seems moderate and fair.

Number of Population.	At per Head.	Total.
	s. d.	£ s. d.
150	1 0	7 10 0
300	0 11	13 15 0
500	0 10	20 16 8
1,000	0 9	37 10 0
2,000	0 8	66 13 4
3,500	0 7	102 1 8
5,000	0 6	125 0 0

"Distant parishes to pay in addition the customary charge for journeys; one journey only being charged to any village on the same day, with the ex-

ception as before mentioned. Thus, while no adequate inducement to needless attendance is offered, the important item of *distance* is fairly and easily provided for."

In workhouses, he proposes that the payment should be per head per annum, graduated according to numbers: journeys also being chargeable where the medical officer resides at a distance, and is suddenly called on. Midwifery cases, dislocations, fractures, and capital operations, to be liberally paid for extra.

Mr. H. W. Rumsey, in the second document of the Appendix, states his views on the same subjects—provision of medicine, and remuneration for medical attendance. Like his colleague, he thinks that medicine and attendance should proceed from different sources, but very properly suggests the difficulty of establishing depôts of medicine in other places than tolerably large towns and Union workhouses.

"In rural districts, where none of these methods could be adopted,—for instance, in places *where no one competent to dispense medicines could be procured*, or where the expense of a separate establishment would be out of proportion to the benefit, or where only one medical officer might reside,—the alteration would appear hardly practicable, and the medical officer might himself continue to provide the medicines."

The scale for remuneration proposed by Mr. H. W. Rumsey does not seem to differ much from that of Mr. Ceeley. He calculates by the number of cases per annum; and his graduation is as follows:—

Number of Cases.	At per Case.	Sum Total.
	s. d.	£. s. d.
25	6 0	7 10 0
50	5 6	13 15 0
100	5 0	25 0 0
200	4 6	45 0 0
400	4 0	80 0 0
800	3 6	140 0 0
1,600	3 0	240 0 0

A second method is also proposed, by a payment, per head, on the average number of *regular* paupers, or those who are in the receipt of relief in money or in kind. Mr. W. H. Rumsey says again,

“The scale for payments according to the number of paupers should be compiled on the same principles as the foregoing scale for a payment per case; but in estimating the respective amounts, it should be remembered that, owing to the change in the administration of relief, the term “pauper” is becoming more and more exclusively confined to the *aged*, the *infirm*, and the *diseased*;—thus of course the rate of remuneration must be *increased* proportionally.”

Journeys, midwifery, and capital operations, to be paid for much in the same manner as proposed by Mr. Ceeley.

The two other papers in the Appendix chiefly relate to the formation of the governing Boards. A Board is recommended consisting of three medical men, two of them appointed by the government, and the third by the medical faculty. But whether the latter appointment should be vested in the heads of the profession or in the whole faculty, the writer does not venture to decide. We think he needlessly raises a question on this point which might lead to much unpleasantness and trouble.

EVENING MEETINGS

AT THE

COLLEGE OF PHYSICIANS.

THE first evening meeting of the season took place on Saturday the 4th. It was very numerously attended, and we observed among the company Lord Melbourne, Lord Goderich, Lord Stanley, several dignitaries of the church, and many other distinguished persons. But it was remarkable—and we heard it made the subject of remark—that very few either of the Fellows or Licentiates of the College were present on this occasion.

The arrangements were in several respects exceedingly bad. The President's chair was placed at one end of the room, of which a portion was separated from the rest by a row of chairs almost as com-

pletely as if it had been railed off. Behind this barrier the company (with the exception of the fortunate few) collected in a dense mass; and as they could not hear, they had recourse to talking, so that there was a constant and rather loud buzz of conversation, by which the voice of the orator was sometimes nearly drowned. It answers much better, and has much less of an exclusive appearance, to place the President's chair in the centre of the room; and it would be a great accommodation, as well as one very easily procured, to have a number of benches (such as are let out for routes) arranged round the sides of the apartment. Neither can we compliment the party who manages the purveyor's department on his success. There were not nearly enough of attendants, and various parts of the equipage (particularly the very necessary one, of teaspoons) were lamentably deficient. We mention these apparently trifling circumstances, because, taken collectively, they tended to produce an unfavourable impression.

The learned President, on whom the task of supporting these meetings seems almost exclusively to rest, read a paper “On the Effects of Cold on the Human Frame.” It was remarkable for the same display of literary lore by which Sir Henry's former Essays have been characterized. We subjoin the paper nearly as it was read, with the exception of some of the more lengthened classical quotations.

On the Effects of Cold. By Sir HENRY HALFORD, Bart. &c. &c.

The learned President began by alluding to Dr. Hawkesworth's account of Captain Cook's voyage round the world, in which we find it stated that Sir Joseph Banks and Dr. Solander landed on Terra del Fuego, and determined to make an expedition into the country in pursuit of some objects of natural history. They were accompanied by a draftsman, and nine other attendants; but previously to commencing their walk, Dr. Solander, a native of Sweden, and well acquainted with the effect of extreme cold in the mountainous country between Norway and Sweden, thought it proper to warn the party against yielding to a propensity to sleep, which the extreme cold and fatigue would inevitably occasion in them, as, if they indulged it, they would wake no more.

This inclination to sleep the Doctor himself was the first to feel, and finding it irresistible, implored the party to go on, and to allow him to follow in half an hour. This could not be permitted after such a warning as he had pronounced, and they dragged him along, and carried him for some time. Nevertheless he slept for five minutes, and it was discovered that the muscles of his feet were become so contracted, that his shoes dropped from them, and he could wear them no more.

The party lost their way in a snow storm, and were detained on shore two days and nights, with a very meagre inadequate stock of provisions, and the unhappy result of the expedition was, that a black servant, and two others of the party, were left behind dead in the snow.

You may remember, perhaps, continued Sir Henry, that Xenophon, in his modest and beautiful narrative of the return of the 10,000 Greeks after their invasion of Persia under the younger Cyrus, whose death in the battle of Cunaxa (near the site of the modern Bagdat), rendered their retreat necessary; encountered some unusually severe weather in Armenia, which proved fatal to a part of the army. It had marched three successive days in the snow, and on the last a strong north wind having arisen, which blew in the faces of the men, thirty soldiers died in one night, seared, as if burnt, and stiffened by cold.

The word *αποκείων*, which is used by the Greek author, is notable, and Virgil expresses the same idea in terms so alike as to be almost a literal translation of Xenophon's account—

“Boreæ penetrabile frigus adurat.”

We have also the same effect of cold described by Livy, in speaking of its influence on the animals passing over the Alps—

“Torrida membra gelu ;”

And Milton has it—

“And frost performs the effect of fire.”

But there are some other military expeditions in modern times, by which we may exemplify the effect of cold on the human frame, operating more disastrously, and more extensively, than on the army of Grecians commanded by Xenophon. When Charles the XIIth, of Sweden, was killed at the siege of

Frederickshall, in Norway, General Ahrenfield, who lay before Drontheim, resolved immediately to withdraw his army to Sweden. It had been reduced by casualties and by desertion to 7300 men, and his enemies, the Danes and Norwegians, were in possession of all the principal roads which led to Sweden. He was compelled, therefore, to make his retreat over a desert, eight leagues in length, lying between Maragher Fidelen and Handeslock. Accordingly on the 11th of January he began to march with his forces. When they had hardly made two leagues of their way, they were overtaken by a storm of snow, which lasted three days and three nights, without intermission. On the 13th January, a lieutenant and fifty men were observed lying dead in a heap with cold. On the 14th, whole squadrons of the Swedes were sunk in the snow; some were trodden under foot by their horses; others had pitched upon their heads, being oppressed by their arms and accoutrements; others lay in whole troops upon each other, still holding their horses, which perished likewise, nothing appearing of some of them but here and there a head raised above the snow. General Ahrenfield himself retired over the mountain of Fidal with 5250 men, of whom only 2000 lived to reach Handel, a fortified town, and that in so miserable a condition that 564 more died soon after, and the remaining 1436 were obliged to march over mountains almost inaccessible; so that only 870 Finlanders arrived at Donnaschantz, in Sweden. In short, the number of those who perished in this march amounted to 5200, out of an army which mustered 7300 when they broke up from Drontheim*.

But the disastrous effect of cold on a retreating army was never more remarkably exemplified than in the return of Bonaparte from Moscow. You remember the insolent triumph with which, after having captured several of the capitals of the continent of Europe, he marched to invade the Russian empire, at the head of an army of nearly half a million of soldiers. He did, indeed, possess himself of the ancient capital of that empire also—*sed qualis rediit?* The determination of the Russians to resist the aggressor to the utmost, and

* From the Historical Register for the year 1719; vol. iv. p. 208—210.

at the expense of any sacrifice, even the voluntary burning of their ancient beloved city, compelled him to remeasure his steps over a country which he himself had laid waste, at a period of the year when frost and snow co-operating with the strenuous efforts of his enemies, so harassed and discomfited him, that out of that immense army not more than 10,000 Frenchmen, and 25,000 auxiliaries, lived to return to their native country; and notwithstanding repeated desperate efforts, made in vain for a while afterwards—

“He left the name, at which the world grew pale,
To point a moral, or adorn a tale.”

No doubt if the great moralist had lived in these days, he would have found a better parallel for Xerxes in Bonaparte's fate, than in that of any other disappointed ambitious monarch who had been arrested in his course, and compelled to desist from his pursuit of what the world has not yet ceased to call glory.

The Emperor of the French left Moscow on the 19th October, when he had ascertained the extent to which the fire had destroyed the resources on which he had depended for the subsistence of his army during the winter; and by the time he had reached Smolensko the frost was become intense; and although he had left Moscow with 120,000 men, and the fragments of various divisions besides had assembled here, it was with great difficulty that 40,000 men could now be brought together in fighting order. The troops often performed their march by night, by the light of torches, in the hopes of escaping their merciless pursuers. When they halted, they fell asleep by hundreds, to awake no more. Their enemies found them frozen to death, around the ashes of their watch-fires. The horses having been ill fed for some time, were equally unable to resist the united effects of cold and fatigue: they sank and stiffened by hundreds and by thousands. The starving soldiers slew others of these animals, that they might wrap themselves in their warm skins, or mitigate the severity of the blast by taking refuge within their disembowelled carcasses.—But enough of these horrors.

The immediate cause of death by cold is apoplexy. The heart is arrested and paralysed in the exercise of its office, and no longer supplies the brain

with arterial blood. Nor is the blood thrown with sufficient force to the extremities. It accumulates, therefore, in the large vessels proceeding immediately from the main spring, and there is no ingress for the blood returning from the brain. The large sinuses, therefore, become over-gorged, and apoplexy follows.

Portal spoke decidedly, many years ago, of apoplexy, as the fatal effect of cold. Dr. Cooke doubted this, because, he said, it had not been demonstrated. Since he wrote, Dr. Kelly has demonstrated it by the post-mortem examination of the bodies of three persons who were found dead upon the sands of Leith, after a night of extraordinary cold.

The philosophy of death by breathing foul or mephitic air, is different. Here the lungs are intercepted in their functions. No oxygen is admitted to the blood, whilst the heart, retaining its activity, sends the blood to the brain charged with carbon; the smallest portion of which is a fatal poison to it. This is the case when death takes place by drowning. The lungs are precluded from receiving oxygen air, and cannot throw off the carbon. Under such circumstances, it has been thought probable that life is extinguished in less than three minutes; unless, happily, the sufferer should have fainted. Then, the heart's action being stopped, the carbon is not thrown upon the brain, and, in such instances, animation has been restored to the apparently dead body, even half an hour after its immersion in water.

The transition from life to death is easy in all these cases. Death by cold is longest in accomplishing his work; but the period of suffering is much abridged where despondency, privation, and fatigue (all of which are likely to be the fate of a retreating army), combine with cold. The unhappy benumbed being feels quite easy; he complains that he cannot move, in answer to solicitations to exert himself, and only desires to be left quiet. Insensibility steals softly over all his system, as the pressure upon the brain increases, and death at length sets his imprisoned spirit free.

When the cold has not been severe enough to destroy life entirely it mutilates the extremities, and mortification ensues from a want of circulation. The Lascars who arrive in this country from

India in the winter season are very prone to this effect of a climate so much colder than their native one, as the records of the hospitals in the city abundantly prove.

Analogous to this is the mortification which sometimes occurs to elderly persons, from ossification of the arteries of the extremities. The blood-vessels having become impervious, the vital principle no longer pervades the feet and the toes, and they perish in consequence.

In confirmation of this opinion of the effect of cold, in a severe degree, upon the human frame, under depression of spirits, and privation, and fatigue, Sir Henry related a hitherto unpublished narrative of the misfortunes encountered by four English gentlemen, in a pedestrian expedition from Contamine to Col-de-Bonhomme, in Switzerland. The walk is one of about three hours, in common circumstances: one of the party was a clergyman, who had lately lost his wife, and had been recommended to travel in order to dissipate his sorrows. He set out, with his companions and a guide, on the 12th September, 1830, at six o'clock in the morning, after a light breakfast. It had snowed in the night, and was raining a little when they started; but in a short time it began to snow again, and continued to snow during the whole of their passage. The path was soon obliterated, and they lost their way. After walking seven hours, the clergyman complained of his inability to proceed further. He said he could not move his legs. The danger of stopping, however, was pointed out; he was encouraged to go on, and was supported, assisted, and carried; but at length he entreated that he might be left, adding that he was quite easy, ready to fall asleep, and must stay where he was. They then wrapped him up in his cloak, and left him, and proceeded as well as they were able; but at the end of eight hours, when they had at last regained the path, and had arrived within a quarter of an hour's walk of the place of their destination, another of the gentlemen failed in his strength, and could go on no longer. The other two, and the guide, attempted to carry him, but they fell headlong continually into the snow; and further exertions to assist him appearing vain, and only to endanger their own safety, he too was left, wrapped up as well as they could wrap him, and seated

upon two knapsacks, and they redoubled their efforts to reach the Col-de-Bonhomme, in order to send assistance to him. They soon reached it, and instantly dispatched seven men to bring him in. He was brought in in the course of an hour, alive, it is true, but he died the next day. A third lost three of his fingers soon after, at Geneva; and the fourth escaped unhurt. We need not add that the poor clergyman was found a corpse.

Yet a cold climate, with the appliances of art, is not insalubrious, nor even incompatible with long life. The proportion of deaths annually in Switzerland is 1 in 59. The proportion in this country is 1 in 60; though in the metropolis, and in Birmingham, it is 1 in 40, if we may believe the latest statistical account. In France, throughout the whole of it, it is said to be 1 in 40; in Italy, 1 in 33; in Rome, 1 in 28, owing, perhaps, to a malaria there.

But what shall we say of Russia? Sir Henry was informed by the late Russian ambassador, that there was a level country, of about one hundred leagues square, sloping to the south, on the borders of Siberia, where a year rarely passed in the course of which some person did not die at the age of 130. On inquiring whether they could depend upon their registers, the reply was, "anybody who knows the practices of the Greek church will tell you that the bishops are more careful of their registration there, if possible, than your parochial clergy are in Great Britain." Is it, then, that these people are longer in coming to their maturity than the inhabitants of southern latitudes, and proportionally slower in their decline and decay, as the oaks of the forest are compared with other trees? Or are they the Hyperborei of the ancients? of whom Pomponius Mela says, "Diutius quam ulli mortalium et beatius vivunt,"—and of whose happiness we read in the Choephoroi of Æschylus, as if it were proverbial—

Τὰντα μὲν ὦ παῖ κρείσσεια χρυσοῦ
Μεγαλῆς δὲ τόχῃς, καὶ υπερβορείου
μειζονα φωνεῖς.

We must presume that these people have the power of counteracting the effects of great cold by artificial resources, as experience and modern ingenuity contrive to provide for the safety of our mariners, who have been exposed frequently of late years, almost with

impunity, to the rigors of a winter, even at the pole.

Such precautions were not known at the time that Sir Hugh Willoughby sailed on a voyage of discovery in those regions, in the reign of King Edward VI. in 1555; and he perished by cold, with all his crew, in Lapland. But now every practicable appliance, on shipboard, is made available as a shelter and protection against great cold,—whilst the soldier on a march, not caring to embarrass himself with cumbersome defensive clothing against only a contingent evil, has no resource against frost and snow, if they should occur, by which he can resist their effects; and he is sometimes arrested and surprised thereby into his destruction. Yet it is found that the life of a soldier is more favourable to longevity than that of the sailor. By the returns of the establishments of Greenwich and Chelsea Hospitals, it appears that the former (Greenwich) contains 2710 pensioners,—the latter (Chelsea) only 509. Now it has been stated to me (said Sir Henry) that of the 2710, several reach the age of 80, and even 90 years, but very rarely indeed, 100. Whereas at Chelsea, containing only 509, scarcely a year passes in which some one does not die at 100.

This remark on the comparative value of life in the two services is not new,—it is as old as Homer. In the *Odyssey*, when Ulysses, having fallen in with the celebration of some games in one of the islands which he traversed in his way home, after the surrender of Troy, was requested to perform some of those feats of activity and of personal prowess for which he had made himself so famous during the siege;—it was remarked, “No; you forget that he has been a good deal at sea since that time, than which nothing contributes so much to melt and break down a man.” Homer’s words are—

Οὐ γὰρ ἐγὼ γε τι φημι κακώτερον ἄλλο
θαλασσῆς
Ἄνδρα γε συγχεῖναι, εἰ καὶ μάλα καρτερός
εἴη*.

For I declare there is nothing like the sea
To break a man, however strong he be.

Sir Henry put it to the judgment of his hearers to decide whether a better reason than the accidents of the two

services for the greater facility of reaching old age on the part of the soldier than the sailor, may not be found in this consideration—that the soldier does not commence his military life before his frame has completely developed itself; whereas the sailor enters upon his duties whilst yet a youth, his manhood remaining to be perfected on harder and less wholesome fare.

In conclusion, the learned President urged that they who would really relieve the poor, should not limit themselves to supplying them with food, but also take care to guard their frames from the baneful, but often neglected, influence of cold.

CHARTERED MEDICAL BODIES; PETITIONS TO THE LEGISLATURE.

To the Editor of the Medical Gazette.

SIR,

As there is now a Parliamentary Committee of the House of Commons, sitting on the subject of the Poor-laws, I would beg to suggest whether it would not be desirable for petitions to be presented from medical men in all quarters, and such other persons, not of the profession, as may choose to join them, praying that the arrangements connected with the medical relief for the poor should be put on a more efficient and satisfactory footing than at present.

It would be important, in my opinion, to direct the prayer to two simple points—one, the doing away entirely with the unworthy and degrading method of tender; the other, the having a fair and moderate remuneration for services, independently of the value of the medicines, so as that there should be no temptation held out, as at present, to do without or be sparing in the use of efficient medicines.

A report of the Provincial Medical Association, and a letter lately addressed, by Dr. Yelloly, to Lord John Russell, have called the particular attention of the public to the subject; and I would submit, whether it would not be worthy of the chartered medical corporations of the country—the Royal College of Physicians, the Royal College of Surgeons, the Apothecaries’ Company (or rather the Court of Examiners), and the Royal Medical Chirurgical Society, and also of the other medical societies of the metropolis—to petition the legislature on a measure so much connected with the credit of the profession of physic, in all its branches.

* *Odyssey*, 8th Book.

you, sir, with your accustomed public would join in the recommendation of procedure, or any other that you may see more, I have every expectation the advantage would be considerable. In gain, I would submit that the maintenance of the subject, as connected with the credit of the profession and the welfare of the poor, should be kept clear from every other. It is of sufficient magnitude and importance to have an independent position of its own.

I have the honour to be, sir,

Your obedient servant,

A RETIRED PHYSICIAN.

Feb 7, 1837.

THE MEDICAL CORPORATIONS AND THE PROFESSION.

PLAN OF PAUPER RELIEF.

Editor of the Medical Gazette.

SIR,
I cannot see how the Colleges or Hall could or interfere about the poor laws, in cases referred to them for their opinion. They have no voice in the legislation, and were not consulted by the framers of the measure on the best mode of providing medical aid to the poor; nor do they know any thing about it, except hearsay, or from references made to them by the government or commissioners, in particular cases referred to them for their opinion; and, as far as the College of Physicians is concerned, they have acted on every such case.

How can the College of Surgeons initiate any proposition? The Commissioners contend that a person legally qualified to exercise the medical profession must not be a member of the College; and the Legislature has always declined to make it imperative on those who choose to become themselves surgeons to undergo any examination, and to prove their fitness. Can the College, therefore, interfere, its members or licentiates of the Apothecaries' Company are employed by the Commissioners, those licentiates not being members of the College of Surgeons? And

Can the College was to interfere, many of who now blame them for apathy should be the first to accuse them of officiousness, in interfering with the interests of their members, who would be proud as being fully competent to take care of their own interests and concerns.

The College has made representation to the Secretary of State, and has received answers (of which correspondence any report of parliament may move for copy) and the value of their interference with the existing powers of the Commis-

sioners may then be estimated. It is to be recollected, also, that the general practitioners must all of them be licentiates of the Hall, and are not of necessity members of the College; but even when they are members, they are still belonging to two learned bodies; and how is the College to act, or to propose regulations for licentiates of the Hall, unless on complaints or representations of circumstances connected with their position as members of the College?

I have read the proposed regulations by Messrs. Rumsey and Ceeley; I have long thought that it would be a good thing to have medical inspectors under the Poor-law Act, like the inspectors of army hospitals, to make periodical visits—say six inspectors for the whole kingdom—who would collect the returns or reports of the various medical officers, and embody them in specific reports to the Commissioners. A Medical Board may perhaps be better—or, better still, if one of the Poor-law Commissioners were a medical man. The general education and habits of a medical man would render him as competent as any other man could be to the general duties of a Commissioner, while his particular professional education would supply a sad want in the establishment. I think there ought to be a medical man attached to every union workhouse or prison, as there is to every other jail in the kingdom; that this person should be of superior attainments; that he should be provided with a house close to the workhouse, with medicines, instruments, and appliances of every sort; that he should have an infirmary attached to, or within the walls of, the workhouse, where out-door paupers might also be received; and that he might also attend the paupers at their own houses, within a certain distance, having a house also allowed him for those duties; and that he should be restricted from all private practice. This would insure good medical aid as far as it extended, and it would prevent any jealousies from the resident practitioners. He would be the best aid to the Guardians in pointing out the proper mode of having medical aid supplied to the more distant parts of the union; and reports, or returns, might be made to him from all the other medical men employed therein. This might save the expense of a Medical Board, or of inspectors, but a medical Commissioner would still be a desideratum,—or two.

"Si quid novisti rectius istis
Candidus imperti—si non, his utere mecum."

Your obedient servant,
CHIRURGUS.

March 5, 1837.

NECESSITY
OF
ENDEAVOURING TO AVERT
THE EVILS OF
THE MEDICAL WORKING OF THE
POOR-LAW.

To the Editor of the Medical Gazette.

SIR,

IT seems to me, that while the great mass of the profession are crying out continually against the working of the medical department of the Poor-law system, they are doing next to nothing to get rid of it! so degrading, and at the same time so inhuman, as its effects will prove if allowed to continue in operation. Why not, as you propose, let every town in England get up a petition to Parliament, signed by all the medical men, with the solitary exception of the hired slave?—and not only would the medical men come forward, but there are many, and I may truly say most of the enlightened inhabitants, who will, for the sake of humanity, affix their names. There is scarcely a MEDICAL GAZETTE published but there is shewn, in its own true colours, the danger of the system, not only to the well-being of our profession, but also to the lives of our fellow-creatures. Degraded enough we are, and have been for many years, without the necessity of having the Poor-law Bill introduced among us, as an artifice to entrap the poor in pocket, but far more slavish in mind. Should the corporate bodies do nothing to avert the deadly stroke that now threatens us with destruction, I think there will be little doubt that they will soon see the day of their downfall; for although some portion of the profession may be silent, and want individual energy in such a cause, yet they are silent spectators of the scene, and have doubtless weighed the question and formed their opinion; and these very persons who now lie dormant, as it were, will, when they see the real state of things, at some future time be roused to action. I hope and trust we shall rise from this state of degradation improved, by having seen for ourselves what our enemies would do to us, had they the power; but it is impossible that this can be the case if we are silent spectators only: we must be up and doing if we wish to save our already falling but noble profession.

Should you think this worthy a place in your valuable journal, by giving it insertion you will oblige me, although

PERSONALLY UNAFFECTED.

March 6, 1837.

ST. GEORGE'S HOSPITAL.

Amputation of the Leg.

THE operations on Thursday, February 16th, were an amputation of the leg by Sir Benjamin Brodie, and an amputation of the leg and lithotomy by Mr. Hawkins. Both the amputations were the usual circular ones below the knee, except that both operators removed the angle of the tibia, according to their usual practice, to avoid the ulceration of the skin that otherwise not unfrequently occurs. Sir Benjamin's case was one of fungus hæmatodes of the foot,—a bleeding and excessively painful fungus following a puncture made in what appeared some time previously to be an abscess. On dissection, the tumor had all the characters of malignant disease, and seemed to be intimately connected with the os calcis, but attached also to some of the other bones of the ankle. The patient suffered a good deal after the operation from fever and delirium traumaticum, but is now doing well.

Mr. Hawkins's amputation was performed for disease of the ankle, which had commenced in the os calcis. In the autumn Mr. Hawkins had performed the usual operation for necrosis, cutting down upon the inner surface of the bone, and removing about a third of it, which had died, and was surrounded by living bone, except on one side. He had left the hospital much benefited by this treatment, but lately returned with abscesses and disease of the joints. On dissection of the limb, the joint between the os calcis and the astragalus was found extensively ulcerated, and both bones much diseased, and the joints of the astragalus in the ankle, with the cuboid and navicular bones, were beginning to show some inflammation and thinning of the cartilaginous surfaces.

Case of Lithotomy—no Stone found.

The case of lithotomy was a little child of two years old, who was admitted with the usual symptoms of stone, irritation of the penis, pain, and stoppage of urine, which was sometimes mixed with blood, and occasionally with pus, and which was sometimes loaded with the lithates, and was at other times alkaline. The child was sounded by Mr. Hawkins, with his colleagues, Mr. Keate, Mr. Babington, and Mr. Cutler, all of whom believed they felt a small stone; and previous to the first incision, Mr. Keate and Mr. Hawkins again thought they felt it with the staff. The incision into the bladder was then made by Mr. Hawkins, the only instru-

ment used being a common scalpel and staff. No stone was, however, felt by the finger, nor could it be distinguished by a sound which was introduced through the urethra, unless Mr. Keate was right in thinking that he still felt it. Some water was then injected into the bladder, and the child sent to bed, and the child was walking about the ward before a week had elapsed from the operation, at which time all the water passed by the urethra. It remains, therefore, doubtful whether there was really a stone, which was small enough to come away with the first gush of urine, and escaped observation, or whether a stone still remains in the bladder, or whether all these gentlemen had been deceived in the sounding, and the symptoms arose from disordered secretion only. Mr. Hawkins at the time remarked to the pupils that the stone could hardly be encysted at that early age, and therefore he thought if there was a stone it might be among the folds of the bladder, and might come away after the operation, as had been the case in some other instances on record. This, however, has not happened. The child, since it has been walking, has sometimes had some suspicious symptoms, which have now lessened, and it has been sounded without any impression having been felt similar to that experienced before the operation*.

Removal of a Cicatrix.

On Thursday, the 23d, the operations were, the removal of a cicatrix by Mr. Walker, and one for ectropeon by Mr. Hawkins. The cicatrix was that of a burn of the chin, which drew down the lower lip in an everted state, preventing the mouth from closing, and occasioning a good deal of inconvenience. A cicatrix from one angle of the mouth had been removed in this girl some weeks previously, and the other angle was operated on in the same way; a triangular portion, including the cicatrix, being removed by a bistoury, as in the operation for cancer of the lower lip, and the edges brought together by hare-lip pins and sutures. The former operation succeeded well, but the girl is at present suffering from an attack of erysipelas, so that the ultimate result of this second operation is still somewhat doubtful.

Operation for Ectropeon.

The operation for ectropeon was that of Mr. Crampton, as modified by Guthrie. The poor girl who was the subject of it

had been tortured by the chronic inflammation of the disease for the whole of her life, and had been several times submitted to operation before her admission, having had portions of the eyelids cut out, and having also had the tarsal cartilages removed (though incompletely), as recommended by Jaeger and Saunders; but when admitted under Mr. Hawkins's care, she was still unable to lift her head up or open her eyes, and was nearly blind in both eyes from opacity of the cornea. The right eye had been operated on by Mr. Hawkins a few weeks ago, and the patient had been so far benefited by the operation, as to be nearly free from the sufferings of twenty years' duration. The same operation was now done on the left eye, though with less chance of success, from the small quantity of eye-lid which remained, and which was partly adherent to the globe; and from the degree to which the cornea was vascular and opaque. Two perpendicular incisions were made in the upper lid, about half an inch in depth, one close to the punctum, the other near the outer canthus; and a portion of the skin of the eye-lid, and of the fibres of the orbicularis muscle, was cut off with a pair of curved scissors. The edges of the skin, where thus divided, were brought together with three ligatures, and the ends of the silk fastened to the forehead with adhesive plaster, with so much force as to hold the eye-lid nearly everted. The girl has now only a very slight pain, which is entirely removed by pinching up a little fold of the skin close to the outer angle (and which will be cut off); and the cornea is already less inflamed, and vision more perfect.

On Thursday, March 2d, the operations were—lithotomy, by Mr. Hawkins; amputation of the thigh, and an operation for necrosis of the tibia, by Sir Benjamin Brodie; after which Mr. Keate removed three encysted tumors from the scalp, and Mr. Hawkins performed a slight operation on the foot.

Lithotomy.

The operation of lithotomy was performed on a lad of 19, by passing a double-edged knife with a beak along the staff, after the urethra was opened, and then a blunt gorget was introduced to enlarge the opening made by the knife in the prostate gland; and the staff being withdrawn, the forceps were passed along the gorget. The stone was a large one (which was the reason for the division of the prostate on both sides), and composed of a good deal of triple phosphate, very soft and brittle, with apparently a lithic acid calculus in the centre. The urine was very albumi-

* We have been thus diffuse with regard to this case, because it has formed the subject of one of those theories of exaggeration and misrepresentation, for which our contemporary is so renowned.

state.

Amputation of Thigh.

The amputation of the thigh was performed for extensive abscesses connected with disease both of the ankle and knee joints. A large abscess was divided by the operator, who dressed the stump by filling it with charpie, so as to avoid all union. The boy has since gone on well.

Operation for Nectosis.

The operation for necrosis was performed very near the tubercle of the tibia, though not interfering with the knee-joint. A sinus leading into the cancellated structure of the bone having been exposed, the orifice was enlarged by a trephine, and some small pieces of dead bone removed from the cavity, which was dressed to the bottom with lint. The boy has unfortunately been seized with erysipelas of the leg, of rather a severe character, which disease has been prevalent during the late cold north winds; but he appears to be now getting better.

Removal of Encrusted Tumors.

The encysted tumors were of the usual character, in an elderly woman; and were removed by cutting into them and emptying their contents, and then removing the cysts. One of them gave a good deal of trouble, in consequence of its having been opened at some former period, which had condensed it, and caused it to adhere intimately to the skin; and the vessels, from the same cause, bled a good deal after the woman returned to her ward.

The operation on the toe consisted of

of luminous phenomena, the Newtonian theory, the hypothesis of Fresnel, and adduced the consequences as fatal to the hypothesis. Fresnel's rectangular plane polarized light was illustrated by polarization by reflection. Cauchy's third law was alluded to. By the explanation, on the polarization theory, the polarized and unpolarized way the properties of light were explained. The former might be explained by the interference of polarized light, and the latter by the interference of unpolarized light. The certain experiments of polarization were explained. The two rays produced by double refraction were explained, and their relative properties were explained on the model.

The hydro-cryc consists of two parts: an intense polarization. The ignition of a cylinder in a wooden box, flame; the mixed Gurney's blow-pipe two-fold—namely and a chamber filled of wire gauze. It is a circular aperture apparatus was attached two images produced crystals, one double of $1\frac{1}{2}$ inches focus was placed the calc.

greatest convexity shall not quite touch. The third lens is brought within a quarter of an inch of the second, by which means a strong light is produced, which is polarized by transmission through a plate of tourmaline; and when a crystal is placed between this polarizing and the second, or analyzing, plate, the light is thus strongly condensed on the crystal.

By this apparatus the lecturer was enabled to shew many of the splendid phenomena of polarized light with the most brilliant success. The coloured rings caused by calc spar, topaz, borax, nitre, arragonite, and quartz, were shewn of colossal size, and of great brilliancy, on the opaque screen. On the whole, it was one of the most successful exhibitions of polarized phenomena yet attempted in the lecture room.

EIGHTEEN TAPE-WORMS IN A SINGLE PATIENT!

Communicated by

DR. ETTMÜLLER TO DR. RADIUS.

THE patient in this case was a young woman, aged 22, of a robust constitution, and who had never laboured under any remarkable affection. Soon after the appearance of the catamenia, she was attacked at irregular intervals with pain in the abdomen, and a gnawing sensation in the intestines, alternating with diarrhoea, sometimes referrible to errors in diet, sometimes occurring without any apparent cause. On many occasions, she was suddenly attacked during her meals with uneasiness and vertigo, which, however, were in general of brief duration. She was also from time to time seized with a violent pain in the belly, which she could not accurately describe, and on such occasions obtained instantaneous, but transitory relief, by taking a draught of very cold water*. She frequently laboured under heartburn, but never vomited; and was subject to fits of oppression of breathing, sighing, and sometimes constant yawning. She suffered much from hemiplegia of the right side, particularly over the eye and forehead, a constant sense of pressure on the globe of the eye, dilatation of the pupils, and swelling of the upper eyelids, giving to her eyes a half-closed, sleepy look. She also complained of pain running from the point of the left shoulder along the collar bone to the sternum, a feeling of stiffness in the limbs, and cramps in the calves of her legs. The catamenia were slow, usually only once every five weeks, and occasionally alternated with leucorrhoea. Her complexion

was yellowish and clay-coloured, her disposition very variable, being sometimes peevish and irritable, sometimes extremely mild. There was no abdominal tenderness present.

She had been treated for amenorrhoea and disease of the liver, and subsequently by Dr. Ettmüller for derangement of the digestive system, for the space of two years, during which no trace of tape-worm appeared. In February 1836, she began to pass small pieces, and this induced him to have recourse to anthelmintics. The treatment employed was that recommended by Schmidt. The preparatory mixture brought away several pieces, from a quarter to half an ell in length. On the 8th of March she took one of Schmidt's pills every hour, from six to eleven o'clock, A.M. She vomited twice during the day, and passed several fluid evacuations, containing several joints of tape-worm. At two, P.M. she was obliged to discontinue the pills, in consequence of the violent retching and gastrodynia which they produced, and took castor oil in half-ounce doses, which she also gave up after the third dose. Towards evening the vomiting ceased, and she fell asleep for about an hour. On awaking she passed a knot of worms, which, when uncoiled, proved to be four entire tape-worms. About one o'clock in the morning, she awoke again with a violent pain in the abdomen, and passed nine more*. She took the same medicine again twice during the two following weeks, and had several slimy discharges from the bowels, without any trace of tape-worm, so that her cure was considered to be complete; and, with the view of improving the digestive function, she was ordered to the medicinal waters at Franzensbrunn. Two days, however, before her departure she passed a portion of tape-worm, and another in July. On her return to Oberwiesenthal in August, she passed two more entire worms. She was now ordered to take the decoct. corticis granati, ℥iij. ad Oj. night and morning. This was continued for five days, and then followed by an active purgative, which brought away three entire worms. In order, however, to render the cure more certain, she was directed to take the decoction a few days longer, and afterwards the compound infusion of senna occasionally. Up to the 24th of December no further traces of tape-worm had been observed†.

* These worms were sent to Dr. Radius, and exhibited by him to the Medical Society at Leipzig. They were all furnished with heads, but had contracted so much from lying in the spirits of wine, that the longest did not measure more than two feet.

* Rosenstein regards this as a pathognomonic sign.

TONGUE SWALLOWING.

A CURIOUS case has been related which links physiology with practice. An infant was labouring under symptoms suddenly arising, and seeming to threaten death by suffocation; the physician, fortunately, discovered that the tongue was retroverted, its apex reaching into the œsophagus; the tongue was readily replaced, with relief to all the symptoms, but the trouble recurred frequently. Many authors have mentioned this *swallowing* of the tongue; I knew one instance where it could be done at will without any serious inconvenience. This occurred in a lad, who, in the playful period of his recovery from fever, was asked to shew his tongue and presented his open mouth with no tongue visible; as soon as his mouth was shut, he asserted that his tongue was in its right place, proving it to be so: there was such facility in retroverting the tongue into the pharynx, that he frequently repeated the trick afterwards. The only other recent instance I have found related, is somewhere recorded on the authority of Magendie. Yet M. Blandin (*Art. Langue, in Dictionnaire de Méd. et de Chir. Pratiques*) follows Boyer in denying that such a displacement can be thus produced, and places the accounts of slaves suffocating themselves by tongue-swallowing “amongst the romances of our science.”—*Mr. Crosse's Retrospective Address.*

POOR-LAW COMMITTEE.

THE members of the Parliamentary Poor-law Committee commenced their labours on Monday last. It is understood that the medical part of the inquiry will not be entered upon till after Easter.

LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE XXIV.

UNSOUNDNESS OF MIND further considered.

Imbecility and its characteristics—Commission de lunatico inquirendo—Miss Bagster's case—Medical evidence on that inquiry—The money and figure test to be applied with discretion. Demi-imbeciles. Deaf and Dumb state—how far connected with imbecility—Persons in that state sometimes not responsible, nor capable of being put on their trial. Cretinism. Mania and its characteristics—Plausible reasoning of some maniacs—Example from the Scotch judicature. Monomania: its characters—With depression—With gaiety—Predominant ideas often changing—Case in illustration—Difficulty sometimes in discovering the subject of the delusion—Anecdotes by Lords Mansfield and Erskine.

In the last lecture I pointed out some of the difficulties which have long beset the subject of unsoundness of mind; and I endeavoured to show how, by the adoption of a series of well-defined terms, and a proper classification, they might in great measure be removed. I also laid before you a plan, which at one view exhibited the mutual relation of all the principal kinds of mental disorder at present recognized by the ablest psychologists, and I went into a detailed account of idiocy and imbecility,—forms of unsoundness which essentially consist in deficiency of mental power.

Imbecility.

In resuming my observations on imbecility, I must remind you of the remarkable trial which I adduced in last lecture as illustrative of the extent to which weakness of intellect may exist, without disqualifying the individual for making a valid will. The medical evidence in that case would seem to have been sufficient to convince any tribunal that there was a decided lack of disposing memory, and a deficiency of reason and understanding inconsistent with a sane devise. But the verdicts of juries are very precarious on these occasions, as may be exemplified by the case of Miss Bagster, a young lady of weak, or rather grossly neglected, mind, (though certainly possessed of a much higher capacity than Frances Smith), who upon contracting an objectionable marriage, was found *non compos*, and afterwards divorced.

Miss Bagster's case.—The proceedings in this case were interesting and instructive, particularly in displaying the methods adopted by some of our "mad doctors," in ascertaining the existence of imbecility with incompetence for managing one's own affairs.

The young lady in question, who was about twenty-two years of age at the time of her elopement and marriage, had been a spoiled child from infancy. She was an only daughter, and treated with a foolish fondness by her grandfather, from whom she was to inherit a very large property. She was brought up in a complete state of dependence on others; all her wishes were gratified without any exertion of mind on her part: she was taught nothing that could give her the least trouble or annoyance in the learning. The management of her temper was also neglected, and school-mistresses and governesses could abundantly testify to various unseemly ebullitions which they had witnessed.

In this state of things, though she cannot be said to have ever arrived at years of discretion, she attained her majority, became legally the mistress of herself and her

property, had her speculations of marriage on hand, and was persuaded by one of her suitors to elope with him. But the person whom she got in this way for a husband, happened to be no favourite of her mother's; and the latter was known to have vowed that he should have her heart's blood rather than her child. There was but one mode of dispossessing him after the union, and that was by proving that the marriage was contracted while the lady was unsound of mind. A writ *de lunatico inquirendo* was obtained, and after an investigation, which lasted eleven days, the desired verdict was returned*.

Let us direct our attention for a few minutes to the medical evidence. Dr. Macmichael was first examined, and deposed that he visited Miss Bagster, in company with Dr. Munroe. She did not appear to be a person of sound intellect, or to possess the ordinary moral perception of a person of her age. The conversation was of a very general and diversified nature: she related all the circumstances of her elopement. "I examined her respecting figures, but she seemed perfectly ignorant of how many pence there were in a shilling. I think she has no reasoning faculty whatever. She said there were six weeks in the year, and six days in the week, and as for Sunday, that was kept holy. I wrote down a common sum in addition, but she could not manage it, and said she was very stupid. She could not add shillings and pence together. I do not think she is competent to manage her own affairs, nor to be trusted with any money. In my opinion she is of unsound mind."

It must be confessed that this looks very like jumping to a conclusion: the girl had been almost wholly uninstructed in arithmetical calculations, and her "tables," it seems, she had always been excused from committing to memory: yet her deficiency in these points, her ignorance, is set down to deficiency of mental power, and she is pronounced incompetent to manage her own affairs.

Dr. Munroe said he was struck with her appearance and manner, which were quite childish: from her physical development, she seemed to be no more than sixteen or seventeen years of age. He and Dr. Macmichael were introduced as friends of Alderman Kelly, in whose house Miss Bagster then resided. She talked freely about the elopement and marriage at Gretna Green. "At another visit, I put to her some *arithmetical questions*: she knew that two and two made four, and four and two made six; but six and four, she said, made eleven, but corrected herself afterwards, and said ten. She could not tell

how many shillings were in a crown, or a sovereign, nor how many tens in an hundred. She said there were six weeks in a year, and when I expressed my dissatisfaction, asked me, 'Is not that right, sir?' Her fortune, she said, added to the Alderman's, would be immense; her's was 700*l.* a-year, his 100*l.* I asked, 'No more?' She then said 150*l.* She knew not how many months in the year. She is decidedly of unsound mind, and not in any degree fit to take care of herself or her property. I should not call her idiotic, or lunatic, but I should describe the state of her mind as that of extreme imbecility. The power of learning language to the extent that Miss Bagster knows French, is consistent with what is called imbecility. I have not the slightest doubt that she is imbecile."

Drs. Sutherland and Gordon deposed to having had very free and confidential conversations with Miss Bagster, relative to the matrimonial trip: she considered it as "a bit of fun." The former gentleman tried her by the *arithmetical test*, and both found her imbecile and of unsound mind.

Another physician improved on the figure test; he examined her touching the interest of money, the expenses of a carriage and horses, and the price of quartern loaves! Only think of Miss Bagster, with the education she received, being asked such a question as this,—we give it from the report of the trial. "I asked her, if she had 10,000*l.* in the *four per cents.*, how much ought to be her income? She answered, 100*l.* a-year. She said she should take a great house at the West End, and keep a number of servants; but she doubted if she could afford to keep a carriage at the same time... Among other questions, I asked her, what would she give for a quartern loaf? She said two shillings. She was aware that twenty shillings made a sovereign, and twenty pence one and eight-pence; but she said that fifty sovereigns were twice as much as a 50*l.* note.... I asked her what would be the expense of a carriage and pair of horses? She said, 'I should think, from 20*l.* to 30*l.* a-year.' He considered her to be of insane mind."

That the arithmetical and money test affords, in many instances, a valuable means of estimating the degree of imbecility, there can be no doubt; but the quotations just made must satisfy most persons that it may be resorted to very absurdly in those cases where the individual has never had an opportunity of acquiring ideas of numbers.

But let us contrast the money-testing method of the physicians just cited with the mode adopted by two other eminent authorities, in the same case. Dr. Alexander Morison, the present physician

* MEDICAL GAZETTE, VOL. X. p. 519.

to Bethlem Hospital, visited Miss Bagster four times previous to the inquiry. "On my first visit," said the Doctor, "she received me politely; said she was in good health, but that she was a little deaf, as she thought, from nervousness. I proceeded to ask her some questions. She told me she had neglected her arithmetic, and was not fond of it. She talked about the Opera, Paganini, Sir W. Scott, and the Exhibition; of a journey she had once taken to Wales. She asked me what was a mad-doctor, and if I was one? I told her no; that I cured all diseases if I could. I then asked her if she had any money in her purse? She said, no; I have no occasion for any, for every thing is bought for me. On my second visit she shook hands with me, and asked after the health of my daughters. She complained of being very nervous, from seeing so many persons, and having to answer so many questions as to her state of mind. She said that Dr. Haslam had frightened her very much, by telling her he was a mad-doctor. On asking her how she became so defective in her arithmetic, she said that her grandfather was very fond of her, and indulged her too much, and would never allow her to be teased about it. She said she could read French, and "Telemachus," fluently. Talking of her trip to Gretna-Green, it was a foolish thing, she said, but you know one reads such things in novels; but I am sure I would not have done so if I thought there would have been all this trouble about it. After some further conversation, she asked me, What do you think of my capacity? I told her that I considered her to be very deficient in her arithmetic, but that I did not think her possessed of less sense than many young ladies of her own age. She asked me if I thought she had as much capacity as was necessary? I said I thought she had. Speaking of her fortune, she said her mother never let her have any money—not even a penny to give to a beggar; and that she had no opportunity of knowing the value of money. After this, she asked a great many questions about the law proceedings which were about to take place; and, finally, without any question, said, 'I have been very violent, and passionate, and undutiful to my mother, for I have sometimes pulled and slapped her, and I am very sensible of the impropriety of my conduct.' My third visit was a very short one. I examined her again upon figures: she put down the first four figures under each other, and in a little time made out ten. She complained of being unwell, from the effect of seeing so many doctors. At my last visit I said, now you are married, how do you think

you ought to sign your name? She said I think it ought to be Newton; but those about me say it was not a marriage, as it was not done in church. I am told by those about me, particularly by Miss Clayton, that Alderman Kelly is in love with me, and will marry me in three months, and I may be Lady Mayoress next year. I said, well, do you think that your marriage with Mr. Newton is not a good one, that you may marry Alderman Kelly? She said, no. I asked her what would her marrying be? She replied, adultery. I have directed much of my attention to insanity of late years, and have written two works on the subject. Miss Bagster is a little deaf, and in that respect only is different from other young ladies. I did not observe the slightest disposition to laugh without cause: she had not the unmeaning laugh and titter of those who are weak in mind. The statements she made I believe to be true, believing her to be a reasonable creature, and that she would not deceive me. I do not believe that her governess had fallen upon the proper mode of instructing her, and *I would undertake in six months to teach her arithmetic and the use of money.* She has begun to think now, and her mind is more opened than it was a year ago, and I think if pains were taken with her, she might be instructed. Such a communication as she is represented to have made to Captain Kelly was very indecent and strange, but in my opinion not inconsistent with sanity. I think that late occurrences, coupled with the repeated conversations with the medical men on these indelicate subjects, have so lessened her sense of modesty, as to account for it. A deficiency of education will account for all the appearances observed in Miss Bagster. *Her incompetency to manage her affairs arises, not from unsoundness of mind, but from ignorance.* She is capable of instruction, so as to be able to manage her affairs. The indulgence of her grandfather, the conduct of her mother towards her, and the frequent change of her teachers, were calculated to produce the results which we see. I hold her to be a responsible agent. She has this proof of soundness of mind, that she is sensible of the deficiencies under which she labours; one test of non-insanity is a consciousness of deficiency."

Such evidence as this is highly satisfactory, consisting, as it does, of a body of facts and opinions collected in an honest straightforward manner, without any deception practised on the alleged imbecile. We find it confirmed, too, by the evidence of Miss Bagster herself before the Commissioners, which is extremely well worth

perusing, and very remarkable, considering the circumstances under which it was given.

But I must not conclude my notice of this case without quoting some passages from Dr. Haslam's evidence. The Doctor has long professed to be a master of evidence, and of the conduct befitting a witness when placed in the box; yet somehow it has frequently befallen himself to be betrayed into extravagances, and unseemly sparring with counsel. In the following extracts, which bear more immediately on the question under consideration, will be observed one or two passages which may serve to point out certain things which ought to be carefully avoided in giving evidence before courts of justice.

Dr. Haslam visited Miss Bagster thrice. On the first occasion the conversation was very general; on the second, Dr. H. announced that he was a "mad doctor," and rendered the lady very nervous; she shed tears, &c. "At my next visit, continued the Dr., I opened a Prayer-book, and desired her to read the seventh commandment, which she did correctly. Do you know, I said, what is meant by committing adultery? Her answer was, when persons are married they shall not have any thing to do with any other man than their own husband. Of her own accord she lamented her deficiency in arithmetic, and her ignorance of the value of money. I then said to her, Do you think you could soon acquire it under proper tuition? She took up those words—Yes; under proper tuition, being allowed to have money and keep accounts, I have no doubt I could learn like other persons: my grandfather was so fond of me that he would not allow the teachers to snub me for neglecting my lessons. From these three interviews I am able to form a correct opinion of her state of mind. She is not a lunatic, she is not an idiot, nor is she of unsound mind.

"*Mr. Pollock:* Is she of sound mind?—I never saw any human being who was of sound mind. That is no answer to my question: is she of sound mind? I presume the Deity is of sound mind, and he alone. Is that your answer, sir? I presume that the Deity alone is of sound mind. How many years have you been a mad-doctor? About forty. Where did you learn that the Deity was of sound mind? From my own reflections during the last fourteen years, and from repeated conversations with the best divines in the country. Is Miss Bagster of sound mind? Competently sound. Is she capable of managing herself and her affairs? I do not know what affairs she has to manage. Is she competent to act as the mistress of

a family? When properly instructed, I think she would be: I mean to state that when certain defects have been supplied, she would be as capable to conduct her affairs as any other woman. Do you understand that with the exception of her defects in education, she is competent to the ordinary affairs of life? I do. Do you think that a part of her disability might be removed by education? I am persuaded of it. Supposing she was taught in the best manner, and by the ablest masters, what length of time would it take? You must state the quantity of learning to be obtained; she is particularly deficient in arithmetic. And what else is she deficient in? Music. Those qualifications are not necessary to enable her to manage the affairs of life? They are certainly not essential. How often have you given evidence before commissioners of lunacy and a jury? I cannot tell; I don't know. Have you any notion? Notion is very much like knowledge, and I don't know. Have you any idea? An idea is a visible perception, and a direct recollection(?). Have you any belief? I cannot say that I have any belief, for that is a direct recollection. Can you, from any faculty of your mind, give information on the subject? Many times and oft I have given evidence on a commission of lunacy; but when I was first examined, or how much time has intervened since, I cannot tell. I did not visit Miss Bagster to repeat arithmetical questions, because she told me she knew nothing about them. I did not go there to puzzle her, though I could easily have done that with many others besides. She is competent to learn arithmetic, but she has not been allowed the materials—I mean money, the great source of all arithmetic."

I have already mentioned what was the issue of the inquiry—a verdict of unsoundness of mind, and incompetency to the management of her affairs. It was certainly a popular finding, for had the verdict been otherwise—had Miss Bagster been found of competent understanding—her person and property would have remained at the disposal of the party who had clandestinely contrived the marriage. Doubt, however, may still be reasonably entertained, whether the verdict was correct, or in strict accordance with truth and justice.

Before I quit the subject, I ought to mention that you may see one or two excellent cases in Dr. Abercrombie's book on the Intellectual Powers, in which the money and number test was judiciously employed in "cognoscing" imbeciles.

Demi-imbeciles.—Orfila describes a class

of unfortunates whom he considers as irresponsible, although they frequently become objects of punishment before the criminal tribunals. They are *demi-imbeciles*, he says, of very limited mental power, and most imperfectly acquainted with those great truths on which social order is based. Among the lower classes, these persons may find a variety of occupations, which require no particular talent for combining ideas; some of them even learn simple trades. Though they may not pass as wholly imbecile among their equals, they are looked upon as singular beings—simpletons—and are made the subject of a thousand tricks and jokes. Many of these individuals, not being restrained by any principle, are given to drink, laziness, or debauchery; and more of them probably fall into the hands of justice than the public are generally aware of. They are dexterous in thieving, and are thought to be very cunning: on leaving prison they begin their old trade afresh, and are thus accounted inveterate culprits. They are sometimes violent, passionate, committing homicide or arson upon the least provocation: those, too, who have strong sexual propensities, are easily betrayed into outrages on modesty. "I have had occasion to notice several individuals of this description in our prisons, who were pronounced reasonable and responsible, yet whose *demi-imbecility* was to me quite manifest."

It is to be feared that many of the young desperadoes who figure frequently before our police magistrates, and are as often sent to the treadmill or solitary confinement, are of this description of *demi-imbecile*. Our magistrates, however deep observers of character, are generally not gifted with a discrimination whereby nicely to distinguish between the responsible and irresponsible; nor in the pressure of business have they the needful leisure for such distinctions.

Deaf and dumb state.—You will recollect that when stating the legal distinctions respecting unsoundness of mind, I mentioned that the person who was born deaf, dumb, and blind, was held in the rank of an idiot, being precluded from the principal ideas of sensation, the foundation of all knowledge. An individual who is deaf and dumb, however, is recognized as responsible when there is evidence of his being able to comprehend the difference between right and wrong, and may be put on his trial, if he can be made to understand the nature of pleading guilty or not guilty. In Dr. Beck's *Elements* you will see a full account of the proceedings adopted some years ago in one of the criminal courts of Scotland, for putting a deaf and dumb woman on her trial,

charged with destroying her infant child by drowning. She was in the end suffered to go at large, untried.

The question of dumbness must be determined by a jury before it can be admitted as a plea for declining trial. If it be proved malicious and pretended, the plea of "not guilty" is to be entered, and the trial proceeded with. Formerly the obstinate pretender was *forced* to plead by whipcord bound round his thumbs: one form of the "thumb torture."

The matter has long since been put beyond a question, that where proper methods of education, like those of the Abbé Sicard and others, have been applied to the deaf and dumb, they are capable of being rendered intelligent and virtuous members of society; and individuals of this class have even evinced powers of mind remarkable for acuteness and sagacity. But, on the other hand, when such beings have been neglected, their uncultivated minds have sometimes rendered them a curse to their fellow creatures: they have indulged in every vice within their reach, and have not hesitated to commit violence when it seemed necessary to enable them to attain their purpose. Such persons are obviously imbecile, and cannot be held accountable for their actions. The difficulty in disposing of them when they come before the legal tribunals, consists in ascertaining the extent of their mental culture, and above all, to determine whether they do not dissemble their attainments in respect to education. Experienced persons must be entrusted with this inquiry; and by such means many desperate impostors have been detected, as we shall hereafter have occasion to notice more particularly when treating of feigned and dissembled states.

Cretinism.—I cannot close this sketch of imbecility without reading for you Dr. Abercrombie's account of the modifications of intellect found among the Cretins of the Vallais. It shows very distinct gradations of deficiency in connexion with bodily disease.

"These singular beings are usually divided into three classes, which receive the names of cretins, semi-cretins, and cretins of the third degree. The first of these classes, or perfect cretins, are, in point of intellect, scarcely removed above mere animal life. Many of them cannot speak, and are only so far sensible of the common calls of nature as to go, when excited by hunger, to places where they have been accustomed to receive their food. The rest of their time is spent, either in basking in the sun, or sitting by the fire, without any trace of intelligence. The next class, or semi-cretins, show a higher degree of intelligence; they remember common

events, understand what is said to them, and express themselves in an intelligible manner on the most common subjects. They are taught to repeat prayers, but scarcely appear to annex any meaning to the words they employ; and they cannot be taught to read or write, or even to number their fingers. The cretins of the third degree learn to read and write, though with very little understanding of what they read, except on the most common topics. But they are acutely alive to their own interest, and extremely litigious. They are without prudence or discretion in the direction of their affairs, and the regulation of their conduct; yet obstinate, and unwilling to be advised. Their memory is good as to what they have seen or heard, and they learn to imitate what they have observed in various arts, as machinery, painting, sculpture, and architecture; but it is mere imitation without invention. Some of them learn music in the same manner; and others attempt poetry of the lowest kind, distinguished by mere rhyme. It is said that none of them can be taught arithmetic, but I do not know whether this has been ascertained to be invariably true; there is no doubt that it is a very general peculiarity."

Mania.

The essential character of this form of derangement (we have now disposed of the forms of deficiency) is a general confusion and incoherence of ideas, succeeding each other with a morbid rapidity, and without any apparent connexion. The perceptions are erroneous. Many maniacs mistake their relations and friends for strangers and enemies: they suppose a window a door, and thus precipitate themselves into the street. These are *illusions* affecting the senses; they have *hallucinations* also, or perceptions of the imagination, without corresponding external objects. They see multitudes of objects which do not exist. They hear voices addressing them, and frequently prompting to the perpetration of some crime. They are subject to violent passion, contempt, suspicion, anger, and hatred; permanent hallucinations, however, are rare: the attention cannot be fixed, the memory is greatly disturbed, and consciousness of existence seems lost. The sense of taste is frequently perverted, and maniacs often refuse wholesome food, preferring offal or any kind of garbage. From the quick succession of their ideas, those who are given to talk have a most plentiful volubility of words, and those who can still write produce compositions of enormous length in a very limited space of time. Their powers of volition are vague and unsteady, and there is an irresistible tendency to motion. The muscu-

lar power is frequently increased: there is a strong disposition to act from the impulse of the moment; and exacerbations of excitement, giving rise to fits of fury, are frequent.

But there are shades and varieties among maniacs; they do not all labour under perversion of *all* the senses; sometimes but one, sometimes two, or three, or four, of the senses are involved. Power of comparison is more or less wanting, according to the degree of deficiency of attention and memory.

Mania has, in fact, been subdivided into three species:—1. Where there is the greatest confusion of the intellectual powers; the ideas erroneous, rapid, and incoherent; illusions and hallucinations prevalent, with a tendency to be readily excited to fury. The maniac recognizes nothing around him; cries aloud, sings, and is constantly in motion; forgets the first wants of nature, and seems destitute of all feeling of cold, heat, or pain. 2. In the second species the maniac is in a state of disturbance, but not to such a degree as to be incapable of having his attention fixed; his answers are correct and to the point, but short. More lengthened conversation discovers the nature of his derangement: all his thoughts are observed to be extravagant; he laughs, sings, becomes excited, and readily flies into fury. 3. In the third kind we have a sort of "reasoning madness," as some have erroneously described it. The individual talks, writes, judges, and appears to reason; while, by a singular contrast, he commits the most obviously extravagant or outrageous actions, yet always finding some plausible plea to justify his proceedings. Perhaps one of the best examples of this species may be found in the well-known case of a Scotch clergyman, which is thus concisely related and commented upon by Dr. Abercrombie:

"A clergyman in Scotland, after showing various extravagances of conduct, was brought before a jury to be cognosed; that is, by a form of Scotch law, to be declared incapable of managing his own affairs, and placed under the care of trustees. Among the acts of extravagance alleged against him was, that he had burnt his library. When he was asked by the jury what account he could give of this part of his conduct, he replied in the following terms:—'In the early part of my life I had imbibed a liking for a most unprofitable study, namely, controversial divinity. On reviewing my library, I found a great part of it to consist of books of this description; and I was so anxious that my family should not be led to follow the same pursuit, that I determined to burn the whole.' He gave answers equally plausible to questions which were

put to him respecting other parts of his conduct. [Among other strange acts, he dug up and destroyed a fine orchard, but pleaded that digging was good for his health, and that he preferred a garden to an orchard.] The result was, that the jury found no sufficient ground for cognosing him; but, in the course of a fortnight from that time, he was in a state of decided mania.

"It is, therefore, incorrect (continues Dr. Abercrombie) to say of insanity, as has been said, that the maniac reasons correctly upon unsound data. His data may be unsound, that is, they may consist of a mental image which is purely visionary, as in the state of perfect mania lately referred to; but this is by no means necessary to constitute the disease; for his premises may be sound, though he distorts them in the results which he deduces from them. This was remarkably the case in the clergyman now mentioned. His premises were sound and consistent, namely, his opinion of the unprofitable nature of the study of controversial divinity, and his anxiety that his family should not prosecute it. His insanity consisted in the rapid and partial view which he took of the means for accomplishing his purpose,—burning his whole library. Had he sold his library, or that part of it which consisted of controversial divinity, the measure would have been in correct relation to the object which he had in view; and if we suppose that, in going over his library, he had met with some books of an immoral tendency,—to have burnt these, to prevent them from falling into the hands of any individual, would have been the act both of a wise and a virtuous man. But to burn his whole library, to prevent his family from studying controversial divinity, was the suggestion of insanity; distorting entirely the true relation of things, and carrying an impression, in itself correct, into consequences which it in no degree warranted."

Monomania.

That form of derangement first distinguished by Esquirol with the appropriate appellation of monomania, is characterized by a delusion relating to a small number of predominant and exclusive ideas, the judgment being often sufficiently sound on every other subject. In monomania the attention is generally fixed on the predominant wrong ideas, while in mania there is such an incoherence and diversity of ideas and actions, as to show that the patient thinks and acts at random.

In monomania with depression, the *melancholia* of the old writers, or *lypemia* of Esquirol, the expression of the countenance is anxious; the complexion is some-

times a dark red, the features being gathered up and motionless; sometimes the tint is sallow. Ideas of terror, distrust, suspicion, and gloominess, prevail; hallucinations are frequent: the patient seeks to be alone, avoids exercise, talks but little; all the bodily functions proceed heavily.

In that form which is marked by gaiety or cheerfulness, the *chæromania* of Esquirol, the countenance is animated, and the eyes often brilliant; the patients are full of activity, bold, petulant, noisy, boasting; and their functions are carried on as in health. They often fancy themselves magnificent, rich, and prosperous, great kings, princes, and ministers: sometimes they personate the Deity himself: some are poets, orators, or great discoverers. Some again are victims to the passion of love, and are carried away by corresponding illusions. Hallucinations also are frequent with them.

From this description of monomania it must be perceived that the variety of which it is susceptible is indefinite, and accordingly there are frequently met with examples of the most novel and extraordinary kind. It is worth observing also, that the predominant ideas often shift and change in the same individual; he labours under a succession of delusions, each prevailing for a time.

A very curious instance of derangement of this kind is displayed in the following case, which will also serve to shew in what a condition of mind a jury may be disposed to consider a person capable of performing a valid or legal act. There is also involved in it the question of a *lucid interval*, one of much importance in legal medicine, which will have to be noticed more particularly hereafter.

In the sittings at Nisi Prius in the King's Bench, in 1809, an action on an annuity bond was brought by a Miss Faulder against the executors and heir of Thomas Clerk Jervoice: the defence was lunacy of the obligor. The young lady had been the mistress of Mr. Jervoice from the age of eighteen, cohabiting with him for twelve years, and conducting herself throughout with singular propriety, and paying every possible attention to his welfare. When he executed the bond in her favour, he did it with peculiar caution, and the preparers of the instruments and the attesting witnesses bore strong testimony to his competency for the act. The bond bore date 1808. The following facts were adduced in evidence by the defendants. The lunatic, on the death of his grandmother in the year 1802, became possessed of an estate in Hampshire, whither he immediately repaired, and whilst the corpse was yet unburied, pulled down the chimneys and levelled the walls of the

mansion, himself living in a marquee, sleeping in a stable or a summer-house, and cooking his victuals with his own hands under a tree in a favourite vessel, which he called his *conjuror*. The carriage of his grandmother was painted black, by his directions, and exposed for sale under the name of Black Jack. Upon the death of his father, he came into the possession of the family estate and residence, situated at West Bromwich, in Staffordshire, whither he repaired, and made a bonfire of all the furniture, himself superintending the conflagration. It was his practice to ride about the country on a jackass, dressed in a white hat, blue trowsers, red morocco slippers, with a flannel shirt next his skin, and over that a white linen shirt, without either coat or waistcoat, wearing sometimes a waggoner's frock. His usual places of residence were tents, stable-yards, or coach-houses, where he cooked his victuals, and even shaved himself, in his beloved *conjuror*, occasionally sleeping on the boards of a parlour, or the stones of a hall. Much of his time was spent in travelling—his carriage being always filled with pots, pans, silver plates, old china, a bunch of large keys, picklocks to the number of one hundred and fifty, and his inseparable *conjuror*. A carriage which he once made use of was unpainted, until a sudden freak induced him to order three female domestics to paint it on a Sunday, and then he rode out in it, the paint being wet. Fishwomen were frequently called to him as they were passing by, whose fish he purchased, and whom he employed in mending the lining of his carriages with the petticoats of his maid-servants. His female domestics, particularly a woman of the name of Elizabeth Savage, whom he picked up at Birmingham, were the companions of his journeys; and he would frequently stop at night on the high roads, making tea and cooking his victuals; on one occasion he performed the process of cooking at midnight on Bagsbot Heath, with numerous candles burning around him, to the no small surprise and entertainment of travellers. Staircases became the objects of his aversion, for he thought them unsightly things; and caused the staircase of his house at Egham to be taken down, substituting a ladder in its stead; passages were moreover cut through the ceilings, through which his servants were sometimes obliged to raise themselves into their chambers by ropes and pulleys: himself occasionally sleeping on the boards of the ground-floor. To his own chamber (when he made use of one) he clambered by means of a chest of drawers filled with large nails drawn out progressively like steps, from the top of which he ascended by ropes. In one of his houses a staircase

turning on castors was erected, to serve as a crane, for the purpose of raising his carriage into his chamber windows. Windows were frequently converted into doors, and the doors blocked up. At length he conceived an aversion to the presence of servants; and, to obviate their attendance, caused the door leading to his chamber from below to be cut in two, so as to form a bar, over which his domestics were never allowed to pass; but they placed his victuals on a table in the inside, connected by a rope and pulleys with that on which he was sitting, and thus were his victuals conveyed to him.

He was confined in a madhouse on the 2d of January, 1809, where he continued to the day of his death. Lord Ellenborough observed to the jury, that although the inquisition which found Mr. Jervoise a lunatic during the period when the instruments in question were executed, was evidence of his insanity, yet that such evidence was presumptive only, not conclusive; and if they should be of opinion, that when he granted the annuity he had such possession of his intellects as rendered him perfectly aware what he was doing, and in making such a disposition of his property had followed the dictates of his mind when fully possessed of reason, their verdict should be in favour of the annuity; provided, on the contrary, they believed him to have been, during the whole period covered by the inquisition, in a state of decided insanity without any lucid interval, the defendants were entitled to a verdict.—Verdict for plaintiff*.

There is sometimes considerable difficulty in detecting monomania, when the particular subject on which the mind is deluded is not immediately known, or does not happen to be accidentally touched upon. Lord Erskine, when acting as counsel for Hatfield, who shot at the King in Drury-lane Theatre, related the following interesting anecdotes, which had been told him by Lord Mansfield.

“A man of the name of Wood indicted Dr. Monro for keeping him as a prisoner when he was sane. He underwent the most severe examination by the defendant's counsel without exposing his complaint; but Dr. Battye having come upon the bench by me, and having desired me to ask him what was become of the Princess whom he had corresponded with in cherry-juice, he showed in a moment what he was. He answered, that there was nothing at all in that, because, having been (as every body knew) imprisoned in a high tower, and being debarred the use of ink, he had no other means of correspondence but by writing his letters in cherry-juice,

* Law Magazine, No. VII.

and throwing them into the river which surrounded the tower, where the Princess received them in a boat. There existed, of course, no tower, no imprisonment, no writing in cherry-juice, no river, no boat; but the whole the inveterate phantom of a morbid imagination. I immediately (continued Lord Mansfield) directed Dr. Monro to be acquitted; but this man, Wood, being a merchant in Philpot-lane, and having been carried through the city in his way to the mad-house, indicted Dr. Monro over again, for the trespass and imprisonment in London, knowing that he had lost his cause by speaking of the Princess at Westminster; and such (said Lord Mansfield) is the extraordinary subtlety and cunning of madmen, that when he was cross-examined on the trial in London, as he had successfully been before, in order to expose his madness, all the ingenuity of the bar, and all the authority of the court, could not make him say a single syllable upon that topic, which had put an end to the indictment before, although he still had the same indelible impression upon his mind, as he signified to those who were near him; but, conscious that the delusion had occasioned his defeat at Westminster, he obstinately persisted in holding it back."

And the following may be added, which Lord Erskine related on the same occasion, as having occurred in his own practice. "I well remember that I once examined, for the greater part of a day, an unfortunate gentleman who had indicted a most affectionate brother, together with the keeper of a mad-house at Hoxton, for having imprisoned him as a lunatic; whilst, according to his evidence, he was in his perfect senses. I was, unfortunately, not instructed in what his lunacy consisted, although my instructions left me no doubt of the fact; but, not having the clue, he completely foiled me in every attempt to expose his infirmity. You may believe that I left no means unemployed which long experience dictated; but without the smallest effect. The day was wasted, and the prosecutor, by the most affecting history of unmerited suffering, appeared to the judge and jury, and to a humane English audience, as the victim of the most wanton and barbarous oppression: at last Dr. Sims came into court, who had been prevented by business from an earlier attendance. From him I soon learned, that the very man whom I had been above an hour examining, and with every possible effort which counsel are so much in the habit of exerting, believed himself to be the Lord and Saviour of mankind; not merely at the time of his confinement, which was alone necessary for my defence, but during the whole time that he had

been triumphing over every attempt to surprise him in the concealment of his disease. I then affected to lament the indecency of my ignorant examination, when he expressed his forgiveness, and said, with the utmost gravity and emphasis, in the face of the whole court, 'I am the Christ;' and so the cause ended."

ON THE
POWERS ON WHICH THE FUNCTIONS OF LIFE IN THE MORE PERFECT ANIMALS DEPEND,

AND ON THE
MANNER IN WHICH THEY ARE ASSOCIATED
IN THE PRODUCTION OF THEIR MORE
COMPLICATED RESULTS.

BY A. P. W. PHILIP, M.D. F.R.S. L. & E.
&c.

[From the Philosophical Transactions, with large additions, communicated to the MEDICAL GAZETTE by the Author.]

In considering the powers of life, I shall in the first place inquire into the seat, the functions, and the nature of each of these powers; and then point out the manner in which they are associated in the production of their more complicated results*.

* The following paper comprehends the results of a task, not of a few months or years, but, with the exception of the time devoted to the more active duties of my profession, of the greater part of not a short life. As far as I can, to render what I have done useful, it is necessary that the various facts should be compared, and thus the inferences they afford ascertained. They are dispersed through so many publications, eleven papers in the Philosophical Transactions, published in the course of twenty years, an Inquiry into the Laws of the Vital Functions, a Treatise on the Influence of Minute Doses of Mercury in restoring the Functions of Health, my Gulstonian Lectures on the more obscure affections of the Brain, &c., that although they are frequently referred to, it has almost always been, more or less, under mistaken views; because the writer, in commenting on one part, has been unacquainted with others with which it is intimately connected, for in so protracted an investigation, few will take the trouble to keep pace with the inquirer.

It will appear from the references in the following paper, how each of the various facts, dispersed through so many publications, has contributed to fill up the great outline of the laws that regulate the animal functions, which has been the object of my labours; and from which the topics of the day have never induced me to swerve. It is evident that this outline must be ascertained before the functions of particular organs can be successfully investigated; all of which, more or less, depend on the general laws of our frame.

The following, I believe, is the first attempt which has been made to ascertain experimentally the seat, the functions, and the nature of all the powers of the more perfect animal, and the various relations they bear to each other, by which

Of the Seat, the Functions, and the Nature of the Powers on which the Phenomena of Life depend.

OF the powers of the living animal, the simplest is that by which the motion of its various members is effected, and which essentially contributes to all its more complicated functions, the contractile power of the muscular fibre, the healthy action of which is not a state of uniform contraction, but of a constant and generally rapid succession of contractions and relaxations, probably the cause of its moderate excitement being (in opposition to the laws which regulate the excitability of the organs of the sensitive powers) followed by no sensible exhaustion of excitability, on which we shall find the most important results depend. Its permanent contraction, we have reason to believe, is always a state of disease. It is followed, unless of very temporary duration, by a sensible exhaustion of excitability*.

Many of the older physiologists supposed that all the powers of the living animal reside in the nervous system. Haller was the first who, in a way that commanded general attention, maintained that the muscular power resides in the muscular fibre itself, and made experiments for the purpose of establishing this opinion.

several, and in some functions all of these powers being enabled to co-operate, their more complicated results are effected. In the latter part of the subject, I have found much care required in rendering the language sufficiently explicit; and if in any instance I have failed in this attempt, I hope it will in some degree be ascribed to the very complicated nature of the subject, arising from the great variety of facts on which the conclusions are necessarily founded.

It will be admitted with respect to the conclusions themselves, that the circumstance of the present inquiry embracing the whole of the subject, is in favour of their accuracy; because in that case, and where, as in the present instance, all the parts are intimately connected, few inferences consequently resting on any single position, an error may betray itself in so many ways, that it can hardly escape detection.

In the Treatises above mentioned, the conclusions being founded on many of the experiments to which I shall have occasion to refer in the following paper, it was necessary as far as this is the case, to refer to their results in these Treatises. As the conclusions of the present paper constitute the object I had in view in all I have done on the subject, it is necessary in it to refer to the results of all these experiments, either as essential to, or tending to illustrate, those conclusions.

There is no other branch of medicine in which misstatements find so ready currency as in the less familiar departments of physiology. Thus it is that the subjects which require the most delicate handling are most exposed to rough usage; and, except among those who make them a serious study (which is not easily done amidst the fatigue and anxieties of a laborious profession), involved in inextricable confusion.

* See papers on the Nature of Sleep and Death, published in the Philosophical Transactions for 1833 and 1834, and republished in my treatise On the Nature of Sleep and Death.

His conclusions, however, were not generally admitted, and the principle on which the point was argued could lead to no decision. It was as easy to affirm as to deny that the remaining nervous influence is the cause of the power which exists in the detached muscle, for it was impossible to separate from the muscular fibre the minute extremities of the nerves with which it is blended, and to them it was alleged that it owes the power, which for a short time it retains after its separation from the brain, spinal marrow, and larger nerves.

The only conclusive means of determining the question, appeared to be an appeal to such experiments as are capable of directly ascertaining whether the effect of the nervous influence on the muscular fibre be that of maintaining, or analogous to the effects of other stimulants, of exhausting its excitability.

It appears from the 32nd experiment, detailed in my Inquiry into the Laws of the Vital Functions*, that the latter is the case to a degree that leaves little doubt respecting the result†; which was confirmed by other experiments, in which I found in many trials, that when the powers of the nervous system are destroyed by opium or tobacco, the loss of power in the muscles is not proportioned to the degree in which the powers of that system are impaired, but simply to the degree in which their contractions had been excited through it‡; and that the removal of both the brain and spinal marrow, which we shall find are the only organs employed in the formation of the nervous influence, does not in any degree impair the action of the heart and vessels, as long as the healthy state of the blood can be maintained by artificial respiration§.

From the whole of these experiments, it appears that the opinion of Haller is correct, that the power of the muscular fibre is not derived from the nervous system, but resides in that fibre itself; a conclusion which we shall find of no small importance in judging of the nature

* In referring to my Inquiry into the Laws of the Vital Functions, the reference is always to the third edition.

† When two sets of muscles of the same description were exposed to the action of the same artificial stimulant, and one of them at the same time to the effects of the nervous influence, it was found that the excitability of the latter was most rapidly exhausted; and this was sometimes the case to so great a degree, that in one instance the excitability of the muscles exposed to both was exhausted in half the time required for its exhaustion in those exposed to the artificial stimulant alone.

‡ The fourth edition of my Treatise on Fevers and Inflammations.

§ Philosophical Transactions for 1815, and my Inquiry into the Laws of the Vital Functions, Part II.

of the nervous influence, and consequently of other functions of the living animal, beside the function of the muscular fibre.

THE powers of the nervous system, properly so called, which cooperate with the muscular fibre in all the more complicated functions, next demand our attention: and it will appear that there is no other branch of physiology in which the generally received opinions have been, and indeed still are, so much at variance with simple matter of fact.

That what in common language is called the nervous system, embraces two distinct sets of organs, is evident; because not only do the functions of the sensorial and nervous organs, properly so called, essentially differ in their nature, but, as we shall find, their localities also are different. Now it has generally been taught that the nervous functions, properly so called, only administer to those of the sensorial power; that they are limited to the conveyance of impressions to and from the sensorial organs, and to the excitement of the muscles of voluntary motion*.

I shall in the first place inquire into the nature of the functions of the nervous system, properly so called, and then endeavour to ascertain to what parts of that system the powers on which those functions depend, belong.

The mere structure of the parts might have led physiologists to suspect that the organs of this system possess other powers than those just enumerated. We find two distinct classes of nerves, to one of which the functions subservient to the sensorial powers evidently belong, and it has never been proved that the other at all partake of these functions. Besides, it had appeared from experiments relating to this second class of nerves, although their results were differently reported by different writers, that they must possess functions of a wholly different nature.

Such were the circumstances which called my attention to this, as it were, superadded class of nerves; and I think it will appear from the facts I am about to adduce, both what are their functions, which we shall find much more complicated than those of the former class, and why the results of the experiments just referred to have been so differently reported.

The most evident peculiarity of structure relating to these nerves is, that while

all the former class proceed either from the brain or spinal marrow, directly to the parts they influence, or which influence them, they either enter or send branches which enter a chain of protuberances called ganglions, from which nerves are sent to the parts influenced by them. Hence they are termed ganglionic nerves, a term, however, which has not been employed in a very strict sense; because, besides the ganglions just mentioned, which receive nerves from different parts of the brain and spinal marrow, there are other protuberances also termed ganglions, which are formed on particular nerves, but which appear to have no relation to any nervous filaments but those of the particular nerve to which they belong. It is therefore necessary that I should define the sense in which I use the terms ganglion and ganglionic nerve. By ganglion, I mean a nervous protuberance which receives nerves from different sources; and by ganglionic nerve, a nerve which either enters or sends branches to such ganglions, or proceeds from them, whether it have or have not, any such protuberance belonging to itself. It may be stated, however, that there is reason to believe that all nerves having such protuberances contribute towards the formation of the ganglions in the sense in which I use the term*.

One of the most evident peculiarities of the ganglionic nerves, in the sense in which I use the term, is, that while the cerebral and spinal nerves supply the sensitive organs and the muscles of voluntary motion, the ganglionic nerves supply the muscles of involuntary motion and the other vital organs.

Haller, finding that the heart cannot be influenced through its nerves in the same way as a muscle of voluntary motion, was led to the conclusion that the former cannot be directly influenced through the nerves. But M. Le Gallois has shown that he was deceived in this inference, the heart being immediately subject to the influence of the spinal marrow; and the latter author further inferred from his experiments, that the spinal marrow is not only capable of directly influencing the heart through its nerves, but that, through the same channel, it bestows on both the heart and blood-vessels all their powers; an inference refuted both by experiments already referred to, and others, an account of which appeared in the *Philosophical Transactions* for 1815, and has since been republished in my *Inquiry into the Laws of the Vital Functions*; and some of which were at the

* See in the Report of the British Association for the Advancement of Science for 1833 a paper by Dr. Henry, of Manchester; and a Dissertation on the state of Medical Science from the termination of the 18th century to the present time, by Dr. Allison, Professor of the Institutes of Medicine in the University of Edinburgh, in the *Cyclopaedia of Practical Medicine*, published in 1834.

* See a paper on the function of the nervous system, in the *Philosophical Transactions* for 1829, which was republished in my treatise *On the Nature of Sleep and Death*.

request of the Royal Society, repeated with the same results by Mr. Clift; Mr. Clift's confirmation of them being published in the same volume of the Transactions.

The circumstance of the brain and spinal marrow only, as we shall find, influencing the heart under peculiar circumstances, is probably the cause of the fact ascertained by Haller, that it cannot be excited through its nerves in the same way as a muscle of voluntary motion, an observation which applies to all muscles of involuntary motion, a want of attention to which has misled some physiologists*.

From the whole of the experiments which have been referred to, it appears, on the one hand, that neither the brain nor spinal marrow bestows any power on the heart or vessels; but, on the other, that each of the former organs is equally capable of directly influencing both, (the vessels, even to their utmost extremities,) and that not only by exciting their powers, but also by impairing, and even wholly destroying them, according to the nature and power of the agent operating on the brain or spinal marrow†; although in their usual functions the heart and vessels, like the other muscles of involuntary motion, obey neither of these organs, but agents peculiar to themselves‡.

Thus it appeared that the ganglionic, like the cerebral and spinal nerves of motion, may administer towards the contraction of the muscular fibre, unless, what I conceive to be more probably the case, although not yet ascertained, branches of the latter nerves are bound up in the same sheath with the ganglionic nerves, as we shall find there is reason to believe is the

case with respect to the nerves of sensation*. Physiology has been much indebted to the experiments of Sir Charles Bell, M. Magendie, and Mr. Mayo, from which it appears that the nerves of motion and those of sensation, although often bound up in the same sheath, are distinct nerves, having different origins.

What are the functions which are peculiar to the ganglionic nerves, in the sense in which I use that term?

This question is answered respecting one of the most important of the vital functions, the process of secretion, in papers published in the Philosophical Transactions for 1815 and 1822, and republished in the last edition of my Inquiry into the Laws of the Vital Functions.

It appears from the experiments detailed in those papers, that when part of the eighth pair of nerves in their passage along the neck is removed, or these nerves are divided, and one end of either portion is raised from its place, the secretion of gastric juice soon begins to fail in its properties; and if the animal survives for a certain time, the contents of the stomach are found not only undigested, but quite dry, proving that there had been no secretion from it whatever for some time.

From these experiments we also learn how it has happened that such various accounts of the effects in the stomach of dividing the eighth pair of nerves is given by different experimentalists; because it was found that digestion was more or less completely interrupted in proportion as the divided ends of the nerves were kept at a considerable distance from each other. Even when the distance was a quarter of an inch, provided the divided ends were no otherwise displaced than in consequence of the retraction of the nerve on its division, digestion, although more or less deranged, was not interrupted, a subject to which I shall have occasion to recur†. Now as this was a point which never particularly demanded attention, accident must always have more or less influenced the result.

* See my reply to MM. Breschet and Milne-Edwards, in the Philosophical Transactions for 1829, entitled, "Some Observations relating to the Function of Digestion."

† It appears, from direct experiment, that both the nervous and muscular powers may be instantly destroyed by suddenly crushing either the brain or spinal marrow. When the experiments on which these positions are founded were first made known to Mr. Andrew Knight, the President of the Horticultural Society, so celebrated for his discoveries in vegetable physiology, partly from motives of humanity and partly to render the flesh of the animals immediately fit for the table, he adopted the practice of killing all the smaller animals by suddenly crushing the brain. Thus, by the instant destruction of the contractile power of the muscles, all stiffening after death is prevented, the flesh at once being rendered permanently tender; a striking proof of the influence of the nervous over the muscular system; and in the account of his mode of killing the animals, published by Mr. Knight, in the newspapers of his neighbourhood, he states that the flesh is thus rendered both more tender and of a better flavour than can be done by the usual method of keeping the dead animal.

‡ See two papers published in the Philosophical Transactions for 1815, and republished in my Inquiry into the Laws of the Vital Functions.

* It appears from the anatomical researches of Mr. Mayo (Outlines of Human Physiology, fourth edition, page 260,) that nerves of motion are bound up in the same sheath with ganglionic nerves. I was not aware that this fact had been ascertained by direct observation at the time the passage to which this note belongs was printed in the Philosophical Transactions. My opinion, as there expressed, was an inference from the general laws of the animal economy.

† In some organs, when the nervous influence is to a certain degree impaired, while the properties of the secreted fluid are altered its quantity is increased, when the nervous power is impaired to a greater degree, the quantity also is impaired; and at length the secreting power wholly fails, no discharge whatever from the secreting surface taking place. The results of the experiments here referred to are well illustrated by some of

But secretion is not the only vital function that is influenced by the division and separation of the divided ends of the eighth pair of nerves in the neck. It appears from experiments detailed in a paper published in the *Philosophical Transactions* for 1827, and republished in my treatise *On the Nature of Sleep and Death*, that, under such circumstances, all the assimilating functions are so deranged that in many parts of the lungs, in the space of fifteen or twenty hours, not a vestige of their healthy structure remains.

Such, it appears, are the effects on the stomach and lungs of depriving them of a considerable portion of the influence of the brain. They are organs well adapted for such observations. In the stomach we have certain means of judging of any considerable deviation in the process of secretion; and from the peculiar structure of the lungs, they are well adapted for observations on changes of structure. That the effects are proportioned to the degree in which the influence of the brain is withdrawn, appears from comparing those of dividing and separating the divided ends of one or both nerves.

It is not, however, to the brain alone that similar observations apply, for it was found that depriving the stomach and lungs of the influence of the spinal marrow is attended with the same effects. When the lumbar portion of this organ was destroyed, the functions of the stomach and lungs, and the structure of the latter, were as much impaired as by the division and separation of the divided ends of one of the eighth pair of nerves; and when the lower half of the spinal marrow was destroyed, as much, as by the division and separation of the divided ends of both those nerves*.

It thus appears that the powers on which the secreting and assimilating functions depend reside in the brain and spinal marrow, and equally in these organs; nor does either of them receive their impressions or act through the other in influencing the vital organs, as the brain is found to do through the spinal marrow with respect to many of its impressions, and in influencing many of the muscles of voluntary motion; the heart and vessels in every part being equally influenced by agents acting either on the brain or spinal marrow, when the other has been removed, as while both, with all their connexions, remain. And the complete division of the spinal marrow at

its middle having no effect in impeding the functions of either the stomach or lungs except in a hardly perceptible degree, proportioned to the small part of that organ necessarily destroyed in its division, the lower contributing to the functions of both the stomach and lungs precisely as it did before its separation from the upper half*. The sensitive functions cease in all parts below the division, because in these functions the spinal marrow only transmits the influence of the brain†.

The question which next presents itself is, how far are the brain and spinal marrow assisted in the foregoing functions by the nerves, ganglions, and plexuses?

In a paper, published in the *Philosophical Transactions* for 1833, and republished in my treatise *On the Nature of Sleep and Death*, I have entered into this question at great length, where such observations and experiments will be found, as far as I am capable of judging, as render the following inferences unavoidable. That the nerves, ganglions, and plexuses, in no degree contribute to the formation of the nervous influence; the spinal and cerebral nerves being merely the means of conveying the influence of the parts of the brain and spinal marrow from which they proceed, and of conveying to these organs the influence of impressions made on their extremities; while the ganglions and plexuses are only the means of combining the influence of all parts of the brain and spinal marrow, through all parts of which the organs of the nervous power properly so called, are distributed; the nerves proceeding from the ganglions and plexuses being the means of conveying this combined influence to the muscles of involuntary motion and the other vital organs.

The question here arises, For what purpose is the influence of every part of the brain and spinal marrow thus combined to be bestowed on these organs?

This question is answered by the experiments just referred to, which prove that the influence of every part of the brain and spinal marrow is necessary to the due performance of the functions of secretion and assimilation; and by other facts to which I shall have occasion to refer, which prove the necessity of the muscles of involuntary motion being under the control of the same power, on which these functions depend.

All of them, as we have just seen, fail when any considerable part of the influence either of the brain or spinal marrow is withdrawn, the failure of function being proportioned to the degree in which

the symptoms of the disease called the Asiatic cholera, which appears, from what I have said in a pamphlet on that disease, to be the effect of the continued operation of a cause, impairing alone the nervous powers, properly so called.

* See my *Inquiry into the Laws of the Vital Functions*, Part II.

* *Inquiry into the Laws of the Vital Functions*, Part II. Exp. 62.

† *Ibid*, Part II.

the influence of either is withdrawn, proving that the influence of every part of them is essential to the due performance of those functions*.

Important and extensive as these functions are, there is still another, hardly less so, dependent on the powers of the nervous system properly so called. Sir Benjamin Brodie† proved by direct experiment many years ago, that animal temperature is under the influence of the nervous system, and various observations evince that a debilitated state of the brain is accompanied with a diminished temperature.

I made many experiments on this subject, detailed in my *Inquiry into the Laws of the Vital Functions*, from which it appears that in this, as in all the other vital functions, the spinal marrow shares with the brain. If the power of either organ be impaired, the temperature sinks in precisely the same proportion as the secretions are deranged. A particular organ may be deranged by preventing its due supply of nervous influence, and there may be no general diminution of temperature. The due nervous influence is prevented reaching the particular organ, but there is no diminution of the power of the brain or spinal marrow. When, on the other hand, the power of either of these organs is impaired, there is an immediate diminution of temperature,—a proof that the maintenance of animal temperature is effected through the medium of the ganglionic nerves, they alone conveying the combined influence of both the brain and spinal marrow. By this means we can by easy experiments ascertain through which class of nerves any function is maintained, and consequently its organs supplied, in cases where the parts are too minute for the labours of the anatomist. It was thus that it was ascertained that the vessels, even to their minutest extremities, are supplied by ganglionic nerves.

When the lower half of the spinal marrow was destroyed the animal shivered, and would probably soon have died of cold, if it had not been kept in a high temperature; and even when the lumbar portion alone was destroyed, a considerable but less diminution of temperature ensued‡.

Thus it appears, from the whole of the

* See papers which appeared in the *Philosophical Transactions* for 1815 and 1827, and my *Inquiry into the Laws of the Vital Functions*, Part II. It appears from what is said in the third part of the third edition of my *Inquiry into the Laws of the Vital Functions*, that a successful practice in diseases of the spinal marrow was suggested by this fact.

† See the *Philosophical Transactions* for 1812 and 1814.

‡ *Inquiry into the Laws of the Vital Functions*, Part II.

facts which have been referred to, that on an influence derived from the brain and spinal marrow, and not from any part, but from the whole of these organs, the secreting and more immediately assimilating functions and the maintenance of animal temperature depend. This influence, therefore, performs a still more important part in the vital than in the sensitive functions. In the latter we find it acting only a subordinate part; while in the former it must be regarded as the great agent, to which all others employed are subservient.

Has the nervous influence any immediate dependence on any of the other powers of the animal frame?

The muscular, we have seen, has no immediate dependence on the nervous power, the only power on which its immediate dependence can be supposed. In like manner the sensorial is the only power on which any immediate dependence of the nervous power can be supposed.

I made an extensive set of experiments, detailed in my *Inquiry into the Laws of the Vital Functions*, to which I shall soon have occasion to refer more particularly, from which it appears that all the functions in which the nervous power, properly so called, is employed, survive the removal of the sensorial power, with the exception, of course, of those in which that power is associated with it. After the removal of the sensorial power the nervous influence still retains all its properties. It is still capable of exciting the muscles both of voluntary and involuntary motion, of, for a short space of time, forming the secreted fluids, performing the various functions of assimilation, so far as to preserve the structure of the parts where it would otherwise have been impaired, and, to a certain degree, of maintaining animal temperature. The nervous, like the muscular power, therefore, is an independent power, having its seat in its own organs, and having no other dependence on the other powers of the living animal than for the due structure of those organs.

Such are the powers of the nervous and muscular systems of the more perfect animals, and the seat and functions of these powers.

They possess, however, two other sources of power, for the sensorial power and the powers of the living blood have no immediate dependence on either of the former powers, or on each other.

That the only dependence of the sensorial power is for the maintenance of its organs, is evident on the most cursory review of the animal economy. The nature of the functions of that power alone

evinces that the living animal possesses no others from which it can be derived; and that the powers of living blood have no direct dependence on its other powers, is proved by the fact, that the blood retains its vital properties after it is separated from the body*.

With respect to the locality of the latter powers, the powers of the living blood, it appears from the fact just stated, existing in itself, must be coextensive with the Functions of secretion and assimilation. At first view it would appear that the functions of the sensorial power, like those of the living blood, pervade every part of the system; the power of sensation seems to pervade the whole frame. On observing the phenomena with more care, however, we find the seat of the sensorial power confined to a small space, when we compare it with that of the nervous power properly so called, the organs of which, we have seen, pervade the whole of the brain and spinal marrow.

The nerves of sensation, in which are included, of course, the nerves of the external senses, and the immediate organs of the sensorial powers, are not parts of the same organ, but distinct parts, having different localities and performing functions of a wholly different nature; that is, the sensorium does not pervade the whole system, but belongs to particular parts. To what parts has never been correctly ascertained, but we know that in man they are confined to certain parts of the brain, with little if any participation by the spinal marrow; although in some of the inferior animals the spinal marrow largely partakes of them, a proof that the sensorium is not, as some have supposed, confined to a physical point, but is of a considerable extent.

Our sensations are referred to certain parts of the body by experience alone. Hence the well-known facts that infants are not aware of the part of the body in which the cause of any sensation originates; and when a limb has been lost, at whatever part the separation is made, we continue to refer to the lost part sensations excited by causes affecting the nerves of the stump.

The function of the nerves of sensation has relation to the sensorial organs alone. The influence they convey is the means by which the sensorium is impressed by distant parts, and such is their only function.

The more perfect animals, then, possess four distinct powers, having no direct dependence on each other, but each we

shall find indirectly dependent on the other three, namely, for the maintenance of its organs.

I am now to inquire how far we can advance in determining the nature of these powers, how far they are peculiar to the living animal, or the same which operate in other parts of nature.

We are in the habit of regarding life as a power of peculiar mystery, but do we find any other principle of action less mysterious? It is not the principle but its properties which are the objects of our senses. A knowledge of the former is not merely beyond the limits, but the nature of our minds. Do we know more of the principle of electricity or gravitation than of life, or is there more uncertainty in noting the property of resistance to fermentation and congelation without any sensible peculiarity in the substances possessed of this property, than that of weight or light? It is not that the nature of life is more obscure than that of any other principle of action, all are equally so, but that its phenomena, being more varied and bearing less resemblance to those of other principles than these bear to each other, are less familiar objects of contemplation.

The subject thus appears invested with an obscurity which does not belong to it, and the perplexity has been increased by vain attempts to remove it; attempts on principles having no relation to the laws by which the phenomena of life are regulated. What possible relation can the laws of mechanics, or any other principle which operates in the inanimate world, bear to the phenomena of life properly so called? It is as much a distinct principle as any of those which operate in that world, and the same method which leads to a knowledge of other sciences must guide us here. There are no means but a study of its phenomena by which we can attain a knowledge of life, that is, of its properties, the only knowledge we can attain of any principle of action. But if our object be to attain a correct knowledge of it, we must first determine with accuracy what are the phenomena of life; for, in the complicated functions of the living animal, it requires not a little patience, labour, and circumspection, to distinguish what part depends on vital powers properly so called, and what on a modification of the powers of inanimate nature. Even the most cursory view must convince us that many of the functions of the living animal partake of the latter power.

Respiration is performed, that is, is drawn into and expelled by means which act on the lungs as the bellows. The blood circulation moves on the same y

* See Mr. Hunter's experiments on the Blood, and the experiments detailed in the last chapter of the second part of my Inquiry into the Laws of the Vital Functions.

water in a set of water-pipes. It obeys a propelling force, and is subjected to the same laws of gravitation. The motion of our limbs is effected by the same mechanical laws by which bodies are put in motion in the external world. Here, as in inanimate nature, velocity can only be obtained by the sacrifice of power. Similar observations apply to the various processes of secretion and assimilation. We can trace in these processes the same chemical laws which obtain in the laboratory of the chemist; but there is at the same time, in all the foregoing functions, something more in operation, analogous to which we find nothing in inanimate nature.

The force, indeed, by which the air is drawn in and expelled in respiration, operates on the same principle as in the bellows; but the powers by which the machinery is worked are the contractile power of the muscular fibre, and the powers of the nervous system, by which the stimulus which excites it is both prepared and applied. The motion of the blood depends on the same principle as that of the water in its pipes, but it is the contractility of the muscular fibre which supplies the moving power. The same observation applies to the motion of the various members of our body.

In like manner, in the processes which maintain the organs of all these functions, and effect the separation of those parts of them which have become useless, and therefore noxious, while we trace the same chemical laws which operate in other parts of nature, we can perceive that they are constantly modified by the powers peculiar to the living animal; for it is not only impossible, by any chemical arrangement, to produce the same results in inanimate nature, but, even by the principles which regulate its phenomena, to trace all the steps by which they are effected. We can neither, for example, imitate the process by which the temperature of living blood is raised above that of the surrounding medium, nor, on the principles of the chemistry of inanimate nature, trace all its steps. No position can be more erroneous than that the chemical processes of the living animal depend alone on the same laws with those of inanimate nature. The properties of life are as peculiarly its own as the properties of gravitation.

I am now to attempt to draw the line of distinction between the powers which the living animal possesses in common with inanimate nature, and those peculiar to itself.

With respect to its mere mechanical powers, to which I have just had occasion to refer, there can be but one opinion, that they are powers common to the living animal and inanimate nature; but with re-

spect to the powers we have been more particularly considering, all of which appear, at first view, to be powers peculiar to the former, the question is not so easily answered. Until it is answered, however, it is evident that we cannot draw the line which correctly separates the phenomena of life from those which result from other principles of action; a line essential to an accurate view of the properties, that is, to a knowledge, of that principle.

The question which I am here to consider, then, is, how far are the sensorial, nervous, and muscular powers, and the powers of living blood, peculiar to the living animal, or possessed by it in common with inanimate nature?

It requires but little consideration to answer the question respecting the sensorial and muscular powers, and the powers peculiar to the living blood. Where do we find, in inanimate nature, a power which can be mistaken for any of them? But even the most cursory review of the functions, which, it appears from the experiments above referred to, are those of the nervous power properly so called, makes us pause. That the oxygen and carbon of the blood combine by the same agency as in the laboratory of the chemist, is a position too probable to be hastily dismissed; and if such be the case, to what other functions of the nervous influence will the same observation apply?

The following, it appears from experiments above referred to, comprehend the nervous functions properly so called:—

1. The excitement of the muscles of voluntary motion in all their functions.
2. The excitement of the muscles of involuntary motion in some of their functions.
3. The maintenance of the processes on which animal temperature depends.
4. The formation of the various secreted fluids. And
5. The more immediate processes of assimilation by which the structure of our various organs is both effected and maintained.

Of these functions, the excitement of the muscles alone is the only one which may be supposed to be the effect of either a chemical or mechanical agent.

In all the healthy functions of life, however, in which the muscular power is employed, the stimulus which excites it, if we except the mere power of distension, appears to be of the former description. Even those stimulants which maintain the functions of the alimentary canal, which, remotely depending on the stimulus of the food, may at first view be supposed to be the effect of a mechanical agent, appear to be wholly of a chemical nature. The

ingesta will not excite a secretion of gastric juice unless they possess chemical properties of a certain description, and the muscular coat of the stomach is not duly excited unless the food has been converted into a healthy chyme, the formation of which, it appears from direct experiments, depends on the healthy state of the influence supplied by the brain and spinal marrow*. In like manner, the healthy action of the intestines, as appears from a thousand observations, can only be maintained when their healthy stimulant has been duly prepared by the chemical processes which take place in the duodenum; which also depend on the influence supplied by the brain and spinal marrow. It is evident that all the other functions just enumerated are of a chemical nature. It thus appears that all the nervous functions are chemical processes, and consequently that there may be an expectation of finding an agent in inanimate nature capable of them.

It was found that in proportion as the nervous influence, properly so called, is withdrawn, all these processes fail. It is evident, therefore, that on this influence the changes observed depend. Whatever, therefore, that influence may be, all its functions, in their general nature, are identical with the effects of the chemical agent, whatever that agent may be, which operates in inanimate nature. This step, therefore, appeared to be gained. Further reasoning, however, was unnecessary, because it was not difficult to submit the question to the test of direct experiment.

I was thus led to consider what power of inanimate nature it was most probable might be successfully substituted for the nervous influence.

An important point had been ascertained. It had been found that of all the powers of inanimate nature, voltaic electricity is most capable of the excitement of the muscular fibre, that is, of one of the functions of the nervous influence. This, indeed, went but a short way towards establishing the identity of the two powers, so many other stimulants being capable of exciting that fibre. It is not to be overlooked, however, that feeble as this argument is towards proving the identity of the nervous influence and voltaic electri-

city, it is powerful respecting the general nature of that influence; because, on the supposition of the nervous influence being a vital power, properly so called, we have here a vital power possessing a property in common with a thousand inanimate agents. Is there any unequivocal instance in which any of the properties of a vital principle, properly so called, is not essentially different from those of any of the principles of inanimate nature? On the whole, the property in question was sufficient to suggest the trial how far voltaic electricity is capable of the other functions of the nervous influence.

No hope of success, of course, could be entertained, unless the artificial agent were employed under the same circumstances under which the nervous influence operates; that is, while the structure of the organs is entire, and their vital properties unimpaired.

Under such circumstances, I substituted it for the nervous influence in the various functions of secretion and assimilation, with success. It was admitted by those who witnessed the results, that these functions were as effectually performed by it, as by that influence itself; and the experiments were afterwards publicly repeated both in London* and Paris†; in the latter, on a great variety of animals, and in both instances with the same results. In the first of my papers published in the *Philosophical Transactions* for 1829, entitled, "Some Observations relating to the Function of Digestion," several circumstances are enumerated which it is necessary to keep in view in conducting such experiments; a want of attention to which has involved the subject in much confusion.

Only one of the functions of the nervous influence now remained which had not been effected by voltaic electricity—the process by which animal temperature is maintained. For the purpose of determining how far it is capable of this function, it was judged the most satisfactory means to expose the living blood to its effects, both in its arterial and venous state. If voltaic electricity operate on the same principle as the nervous influence, it will raise the temperature of the former, but not of the latter, which has already undergone the operation of that influence. Such was

* *Philosophical Transactions* for 1815 and 1822, and *Inquiry into the Laws of the Vital Functions*, Part II. In an animal which has survived the division and separation of the divided ends of the eighth pair of nerves till the contents of the stomach, from the failure of nervous influence, have become quite dry, however much distended with food it may be (the circumstances under which the greatest mechanical stimulus is applied to the muscular fibres of the stomach), not even the slightest degree of its healthy action is excited, no part of the undigested food being propelled into the duodenum.

* *Philosophical Transactions* for 1822. The *Journal of the Royal Institution of London* for 1822. See also the *London Medical and Physical Journal* for May, 1820, vol. xliii. p. 385.

† De l'Influence du Système Nerveux sur la Digestion Stomachale; par MM. Breschet, D.M.P. Chef de Travaux Anatomiques de la Faculté de Médecine de Paris, &c.; H. Milne-Edwards, D.M.P.; et Vavasseur, D.M.P. (Mémoire lu à la Société Philomatique, le 2e Août, 1823.) Extrait des *Archives Générales de Médecine*, Août, 1823.

found to be the case. The arterial blood immediately rose several degrees on coming into contact with the voltaic wires, but there was no increase of temperature in the venous blood, although, in both instances, the blood was subjected to them as it flowed from the vessels; it having appeared, from previous experiments, that the delay of even a few minutes, although no apparent change had taken place in the blood, and no elastic fluid had been disengaged from it, prevented any rise of temperature; so rapidly do some of the properties of living blood undergo a change after its removal from the vessels*.

Such being the facts, I could no longer doubt that the nervous influence and voltaic electricity are powers of a similar nature, and it appeared to me that this would be most convincingly illustrated, by causing the nervous influence to pass through other conductors than the nerves; because such a fact would, independently of all others, prove that it is not a vital power properly so called, it being acknowledged on all sides that no such power admits of separation from the texture to which it belongs in the living animal.

With this view I made many vain attempts, and hardly escaped the ridicule of my associates for expecting that the nervous influence could exist in any texture but that to which it belongs in the living animal.

In the third edition of my *Inquiry into the Laws of the Vital Functions*, the reader will find the circumstances detailed which led to the successful experiment, the result of which was publicly confirmed both in London and Paris; and those who in the first instance ridiculed my expectations, joined me in stating that such is the fact.

The cause of failure in my first experiments on this subject, was the circumstance of having made a wrong choice of the nerve on which I operated, which was a nerve of voluntary motion.

It will appear on reflection that this was a wrong choice. Before we can expect that the nervous influence can be made to pass through any other conductor than that to which it belongs in the animal body, there must exist a powerful cause soliciting it to some particular point. In a muscle of voluntary motion there can be no such cause. The nervous influence is not attracted to the muscle, it is sent to it by an act of the sensorium, carried into effect by the powers of the nervous organs, which are subjected to its influence; those organs which, on the one hand, prepare that influence, and those which, on the

other, convey it when duly prepared. The muscle is altogether passive till the influence is applied to it. But the case is wholly different with respect to the seat of many of the functions of the ganglionic system. We know, from direct observation, that in many of them there is a cause continually operating, which solicits the nervous influence to their organs.

In these organs the living blood and nervous influence co-operate in the functions of secretion and assimilation; and it is an acknowledged fact, that when an increased determination of blood to secreting organs takes place, there is, in the same proportion, an increase of their secreted fluids; a result which cannot arrive without a corresponding supply of nervous influence. Thus we know (as, indeed, we had reason to expect) that the presence of the living blood in the secreting organs solicits a proportionable supply of that influence; and thus it was, that whereas, while I operated on the nerves of voluntary motion, my attempts were wholly fruitless, the very first attempt with the ganglionic nerves was crowned with success; nor, since the repetition of the experiments in London and Paris, has the fact been questioned.

If the facts I have stated be correct, we can have little doubt that the nervous influence is of a nature similar to the inanimate agent which was substituted for it; for to say nothing of the circumstance of the nervous influence being capable of existing in a texture different from that to which it belongs in the living animal, we cannot suppose that there are two distinct powers, the one of which is capable of all the effects of the other; or I would rather say, that such a supposition amounts to a contradiction in terms, because as it is acknowledged that we know nothing of any principle of action but by its properties, it necessarily follows, that by these alone it can be distinguished.

In discussing the nature of the nervous influence, too much has been ascribed to electric tests, which are referred to as if they possessed a power equal to that of chemical tests. A correct chemical test will give evidence of what we are in quest of under all circumstances; and is therefore capable, in all instances, of detecting its presence, and consequently its absence also. This arises from there being but one counteracting power, that of affinity. If the affinity be stronger in the test than in any other substance, the effect of all other affinities is destroyed. We possess no such electric test, because here there may be other counteracting causes beside the

* See the second part of my *Inquiry into the Laws of the Vital Functions*, Experiments 80, 81, 82, 83, 84, and 85.

* See the second of my papers in the *Philosophical Transactions* for 1829.

power of affinity—opposing currents, for example. Besides, we know that the properties of electricity are so modified by the powers of life, as greatly to interfere with its relations to our tests. The electricity of the torpedo and other electric animals does not affect the common electrometer, yet no one has doubted its identity with the electricity of inanimate nature.

Although electric tests, therefore, give evidence of the presence of electricity, we cannot by their means prove its absence; a fact with which we should not have been acquainted, were it not, under certain circumstances, possible to prove the presence of electricity without their aid; that is, the presence of electricity may under certain circumstances be proved, where it is not indicated by any of the properties generally admitted to be peculiar to it.

Suppose it were said, for example, that we cannot admit that electricity is the agent in the combination of oxygen and carbon, because there is no test by which its presence can be detected; the reply of Dr. Faraday, I conceive, would be—we cannot at present, whatever we may do hereafter, make the electricity employed in effecting this combination evident to any of our tests; but I consider its presence as a necessary inference, because I have adduced facts which prove, either that electricity is the agent in such combinations, or that nature here deviates from the simplicity observed in all her other works. Either electricity is the agent in the combination in question, or there are two kinds of chemical affinity.

Under such circumstances, can any other reply avail except either disproving the facts, or pointing out the fallacy of the inference?

What I have done is strikingly illustrated by the late investigations of Dr. Faraday. It is more than twenty years since I found that voltaic electricity is capable of all the functions of the nervous influence; it now appears from the facts, on which he has founded his doctrine of electro-chemical equivalents, that electricity is the agent in all chemical processes*. According to the inferences of Dr. Faraday, therefore, the experiments, which prove that the nervous influence is the agent in the functions we have been considering, all of which we have seen are chemical processes, are sufficient to prove its electric nature; and we are now also, on the other hand, furnished with direct proof that the brain is capable of collecting and applying, even according

to the dictates of the will, the electric power.

Dr. Davy, in his last paper on the Torpedo*, observes, that “when the brain has been divided longitudinally, the fish has continued to give shocks†; when the brain has been entirely extracted, the fish instantly lost this power, though the muscles generally continued to act powerfully;” from which it appears that the electric power is not like the muscular, independent of the brain, but, on the contrary, immediately depending on it; proving that in this, as in all the other nervous functions, as appears from the facts stated in a paper which the Royal Society did me the honour to publish in 1833, and which was republished in my Inquiry into the Nature of Sleep and Death, the nerves are merely the passive, the brain one of the active, parts of the nervous system‡.

In the foregoing positions we here find, as in other similar instances, that when truth is once arrived at, other facts, beside those which led to it, arise (and still others will present themselves as we proceed) to give it their aid.

Dr. Davy made no experiments to determine how far the spinal marrow, the only other part of the nervous system concerned in the formation of the nervous influence, partakes of the function in question. Were we to reason from the analogy afforded by all the other nervous functions properly so called, we should expect to find the spinal marrow sharing it equally with the brain. It is not unlikely that the removal either of the brain or spinal marrow would destroy this function, as is found to be the case with respect to the more complicated functions properly termed nervous—a point which can only be determined by an appeal to direct ex-

* Philosophical Transactions for 1834.

† A fact analogous to the division of the spinal marrow leaving unimpaired its influence on the secreting and assimilating organs.

‡ The electric organs in the animals called electric are either the means of both collecting and applying the electric power, or of applying it only. As it appears from the experiment of Dr. Davy, referred to in the text, that the brain is essential to the electric function, it follows that this organ either itself supplies the electric power, or enables the electric organs to perform this office. That the former is the case, and consequently that the electric organs are only the means of the application of the electric power, appears from our finding from direct experiment that all the other nervous functions of the brain, properly so called, can be performed by the electric power supplied by other means, and that in all the nervous functions, the nerves (which so copiously enter into the composition of the electric organs, the great supply of nerves being proportioned to the intensity of the electricity required for the function of these organs) are only the means of conveying the influence supplied by the brain or spinal marrow.

* Dr. Faraday's papers in the Philosophical Transactions for 1832, 1833, 1834, and 1835.

periment; or, like the excitement of the muscles, it may belong to either organ separately, or it may, being a function of volition, belong to the brain alone.

In addition to the foregoing statements I may refer to the success which has attended the employment of voltaic electricity in those diseases which depend on a deficient supply of nervous influence*.

That we may have a clear view of the line of distinction between the sensorial and nervous powers, a more particular consideration of the former is necessary.

THE following points, we have seen, are made out from the phenomena of every day's experience, that the organs of the sensorial power and the nerves of sensation, in which, of course, are included the nerves of the organs of the external senses, are distinct organs; the former being the immediate organs of those powers, the latter the organs which excite them.

We have just seen reason to believe that the influence conveyed by the nerves which excite the muscles, and maintain the secreting and assimilating functions and the due temperature of the animal body, is a power which operates in inanimate nature; because, on the one hand, we have found such a power capable of all the functions of the nervous influence, properly so called; and, on the other, that this influence is capable of existing in other textures than those to which it belongs in the living animal, proving that it is not a vital power, properly so called.

Are the properties of the influence conveyed by the nerves of sensation the same with those of any of the powers of inanimate nature, or can this influence exist in any texture but that to which it belongs in the living animal?

It is enough to say that its only property is that by which it is enabled to co-operate with the immediate organs of the sensorial power. To such a property we not only find that there is nothing analogous in any of the properties of inanimate nature; but, as will more fully appear from what I am about to say, that the organs of the sensorial power are, in their healthy functions, unapproachable by any of its agents: it is therefore perhaps unnecessary to add, that we know of no texture in which the influence conveyed by the nerves of sensation can be supposed to exist, but that to which it belongs in the living animal.

The nerves of sensation, therefore, belong to the sensorial, not to the nervous

power. They convey an influence of a wholly different nature from that conveyed by the nerves of the latter power; and the only analogy which can be traced between their function and the operations of inanimate nature is, that it is excited by impressions received from the agents of the external world; to which we are indebted for all our knowledge of that world. The action of the immediate organs of the sensorial power, we have seen, being thus excited by one vital part acting on another, and by its vital properties alone, all analogy with the operations of inanimate nature here disappears.

While the other functions of the living animal are the results of inanimate agents acting on living parts, or living parts on them, in the sensorial functions we see the effects of vital parts acting on each other, and that by their vital properties alone. Hence the analogy between the former and the operations of inanimate nature, and, with the exception just pointed out, the total loss of all such analogy in the latter.

Whence is it possible to conceive that such analogy can arise, except from the operation of some of the agents of the inanimate world? As no analogy can exist where there is not some property in common, and where any property is observed, there the agent to which it belongs must operate, it necessarily follows that in all cases where any analogy can be traced between the functions of life and the operations of inanimate nature, there some of the agents of the latter must operate. When the phenomena of the living animal are carefully compared with the preceding facts, it will be found that in every instance in which any analogy between its functions and the operations of inanimate nature is observed, the interference of such an agent may be detected.

WE have now considered, individually, the various powers of the more perfect living animal. We have found in it, beside the mechanical powers which, it will be admitted on all hands, it evidently possesses in common with inanimate nature, four distinct powers; three of them vital powers, properly so called—that is, powers having properties essentially different from those of the agents which operate in inanimate nature. In the fourth alone we recognize one of these agents; for we find it can exist in other textures than those to which it belongs in the living animal, and that we can substitute for it one of the powers of inanimate nature, without deranging the functions of life.

As it is admitted that the living animal partakes of the mechanical, should it surprise us to find that it also partakes of the

* See my paper in the Philosophical Transactions for 1817, and Inquiry into the Laws of the Vital Functions, Part III., and my Treatise on Indigestion, 7th edition.

chemical powers of inanimate nature? It appears from the experiments of Dr. Faraday, above referred to, that it is only as it partakes of the electric, that it can partake of the latter powers.

All the foregoing powers are employed, although in a very different way, in the construction of two systems in a great degree distinct; the end of the one being the maintenance of our bodies, of the other our intercourse with the world which surrounds us.

In the remaining part of this paper, I am to consider the various relations those powers bear to each other in the maintenance of the foregoing systems; and the way in which these systems themselves are so related, as to form the animal body into a whole, in which no part can be affected without tending more or less to influence every other.

This part will appear in the next number of the GAZETTE.

SUCCESSFUL LABOUR,

WHERE THE PELVIS WAS GREATLY DEFORMED AND CONTRACTED.

To the Editor of the Medical Gazette.

SIR,

THE accompanying case will, I think, prove interesting to your readers.

Your obedient servant,

GEO. S. LILBURN, M.D.

24, Harley-street, March 10, 1837.

The wife of a respectable engraver was recommended, by a celebrated surgeon of this metropolis, to place herself under my care on her approaching confinement with her first child. She is a short woman, and has deformity of the pelvis, from protrusion of the sacrum anteriorly, which could be distinctly ascertained on a common examination per vaginam.

On the 4th April, 1834, the labour pains began, and lasted fifteen hours; during which time I bled her freely. When the child was born, its head was considerably elongated, the parietal bones overlapping, and the animation suspended: by bleeding it from the umbilicus, inflating the lungs, using the hot-bath, and external stimuli, it cried after little more than three quarters of an hour. The mother suckled her infant, and had not one unfavourable symptom during her convalescence.

She again became pregnant, and applied to me to attend her. The labour pains began on the 23d June, 1836. On examination, I found the deformity had considerably increased, the antero-posterior diameter of the pelvis measuring certainly *less than three inches*. She had neglected to send for me until the membranes were ruptured, and the child's head was fixed at the brim of the pelvis. The pains were severe, and having remained with her more than six hours with no advancement, and the head so firmly impacted that I feared rupture of the uterus, I determined, if no advancement took place within an hour, to perform craniotomy. I had bled her, and in some degree produced relaxation of the os uteri and vagina. After waiting the full time, I sent to my friend Mr. Wooldridge, of Jermyn-Street, to assist me in the operation, having experienced his valuable services on previous occasions. We had met but a very short time when the patient gave a most piercing shriek, and I dreaded what might have taken place (rupture of the uterus). To my great surprise and satisfaction, however, I found the child's head in the cavity of the pelvis, and in half an hour it was in the world—the animation suspended. We moulded its head (which was sadly mis-shapen), bled it from the umbilicus, inflated the lungs, used the hot-bath, &c. for upwards of an hour and a half before any signs of animation appeared; the child then gasped, the left eye opened, then the left arm twitched, then the left leg; the right side was entirely paralysed, and remained so five hours. I kept the mother upon water-gruel for five days; she suckled her child, and had no unfavourable symptom during convalescence. Both this and her first child are strong, and as fine healthy boys as any in London.

DEATH OF THE FŒTUS,

FROM WINDING OF THE UMBILICAL CORD
ROUND THE NECK.

To the Editor of the Medical Gazette.

SIR,

IN the MEDICAL GAZETTE, part the second, session 1836–7, p. 231, is a note from the Editor, desiring to be

favoured with the particulars of the case "where the child was strangled by the umbilical cord," &c. &c.

In consequence of which, I beg to furnish you with a case to the point, and which occurred to me 26th November last, in this town, where I have practised as an accoucheur for more than the last fifty years. On the day above-named, I was requested to attend on a lady, whom I found in labour of her third child, which labour was rather premature, as she did not expect to be confined, by her *own reckoning*, for six weeks. On examination I found the breech presenting, and between the pains I could to a certainty perceive the child move, and therefore alive, the lady herself noticing that her child was alive, that she felt it strong at the beginning of, and during labour. The os uteri being fully dilated, the child was soon forced down by the pains to the os externum, and there it rested (contrary to my hopes and expectations, the child being so small) for several pains; for I concluded its expulsion would be almost immediate, as one of the nates, or ischia, had protruded a little through the os externum: this circumstance was easily accounted for after the birth of the child, as the umbilical cord was tightly wound round its neck many times, which, in my opinion, retarded the expulsion of the child, and was the direct cause of its death. After I had separated the child from the placenta, I found it loose in the vagina. In my long practice I do not recollect such a clear case of strangulation at the birth, from the umbilical cord being twisted round the child's neck, as I have detailed to you; nor should I have taken notice of this one, had I not read your note at the foot of Mr. Thompson's case. I recollect pointing out to the husband of the lady, who is a young surgeon, and who was in the room at the child's birth, that the child was dead, and shewed him how the navil-string was wound round the child's neck so tight, and that it was the cause of its death.—I remain,

Your obedient servant,
W. C. HUNT.

Dartmouth, March 6, 1837.

In a subsequent note, Mr. Hunt writes:—

I beg to correct an expression in my letter, sent two days ago. I think the

word *strangulation* is misapplied; it ought to be, that the circulations of the umbilical cord round the child's neck, made such a pressure on the vessels of the funis as to stop the circulation of the blood; thereby destroying the child's life. Had the infant ever breathed, then the word *strangled* would have been properly used.

March 8, 1837.

BARK OF THE ROOT OF POMEGRANATE IN TAPE-WORM.

To the Editor of the Medical Gazette.

SIR,

FROM reading the account in your last number of the extraordinary case of the eighteen tape-worms, I observe the last medicine prescribed was—

Decoct. Granati, 3iij. ad. Oj.,

which brought away three entire worms.

My object in addressing you is to state, that the infusion of the fresh bark of the root of the pomegranate tree is considered as almost a certain cure for tape-worm in India, both with the Europeans and natives; and also to add the mode of preparing and administering it, as, if any practitioner, from the case related, should use the infusion of the bark of the fruit, which is known to be useful in chronic cases of dysentery and diarrhoea, he would feel disappointed, as I believe it is not of the slightest use in tape-worm.

R̄ Cort. recent. Radic. Punic. Granati, ʒviij., Coque in Oijj. Aquæ ad Oij. Cola.

Of this decoction the patient is to drink a wine glassful, and to repeat that quantity at longer or shorter intervals, as the sickness and faintness, which it generally produces, will allow, until he has drunk the whole. The worm is generally voided in a few hours after the patient has begun to take the medicine, and not unfrequently comes away alive.—I remain, sir,

Your obedient servant,
P. LESLIE, M.D., M.R.C.S.L.

Wilton-Place, Belgrave-Square,
March 14, 1837.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abrégé."—D'ALEMBERT.

Practical Observations on the Venereal Disease, and on the Use of Mercury.

BY ABRAHAM COLLES, M.D., Surgeon to Steevens's Hospital, and late Professor of Surgery in the Royal College of Surgeons in Ireland. 8vo. pp. 352.

MEDICAL authors are in general divisible into two classes—first, those who write to get a name, that it may be said—"Mr. so-and-so is an author;"—and secondly, those who write for the sake of communicating to the world the results of their experience, and so affording to others the means of participating in the benefits resulting from the opportunities which they may have enjoyed.

To this latter class belongs the author of the work before us. Dr. Colles has been long in the enjoyment of the highest reputation as a practical surgeon: not content with having, as Professor of Surgery to the Dublin College, communicated his precepts to a large number of the present and rising generation of Irish surgeons, he now comes forward, while yet in the full vigour of his intellect, to narrate what he has seen and learned in the course of a long and extensive practice among all ranks, for the benefit of his junior professional brethren.

It may be presumed that this is a purely practical book: we have here a good practical description of the various forms in which venereal symptoms, both primary and secondary, present themselves, and most valuable observations on the mode of treatment. The author's second chapter, "on the administration of mercury," highly deserves an attentive perusal: he insists upon every patient being put through a preparatory process prior to a course of mercury, and attributes much of the disrepute into which this remedy has fallen to the neglect of this process.

We have not space to give an analysis of the subjects treated of in this work, but we cannot omit a particular reference to the chapter on syphilis in infants, which contains the most complete and interesting history we are acquainted with of the phenomena of that disease at this early period of life.

A second part of the work is devoted to the use of mercury in diseases not venereal: this part might have been somewhat more extended without being tedious; nevertheless, it contains the narrations of several cases highly illustrative of the efficacy of the remedy. We can with perfect sincerity say that we have read every part of the book with much interest and instruction, and recommend it as highly deserving a place in every practical man's library.

MEDICAL GAZETTE.

"Licet omnibus, licet etiam mihi, dignitatem Artis Medicæ tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

PROSPECTS OF LEGISLATION FOR THE PROFESSION.

MR. WARBURTON'S LABOURS.

SEVENTEEN to four in a Committee of twenty-one, is a proportion which promises at least despatch of business. Seventeen Poor-Law supporters will make quick work with four opponents, while upon these four the task of bringing the merits or demerits of the medical arrangements of the system before Parliament, almost entirely devolves.

The Committee, it may be said, was formed in the usual way, and without any view to partiality. How odd, then, that upon its formation, when the real state of things was made manifest, a motion, expressly intended to balance inequalities, or at all events to approach such a desirable end, was discountenanced. Mr. Walter's simple and fair expedient of adding six members more to the Committee, whereby the friends of thorough inquiry would have been increased to ten, still leaving seven majority on the other side, was rejected on a division. But the numbers that divided on the occasion afforded a satisfactory demonstration. Allowing for the votes of the adherents of the party in power,

so tenacious of the present Poor-Law, and clinging to it as they do to other things much more substantial, the minority was sufficient to show that there is still hope of success, when the present aspect of affairs is altered. We have long since said that it was impossible to entertain any very sanguine anticipations from the embodiment of Lord John Russell's scheme; nor has any thing since occurred to induce us to modify our opinion. In the event of a dissolution, however, hopes must rise, and the prospect decidedly brighten.

In looking over the list of the Committee, many, we doubt not, will have been struck with the absence of Mr. Warburton's name. What has become of Mr. Warburton, that great patron of the profession, the late presiding genius of the Medical Education Committee? Is he laid up with the *grippe* or the gout; or why is he not forthcoming? Such must have been the affectionate inquiry after the honourable member for Bridport, by those who afar off were charmed and enchanted with the loudly-trumpetted exertions of the famous chairman — by those who fancy that a patriot and a great man ought never to slumber or sleep, but that he should persevere to the death in the glorious path in which for a time he moved.

But is human nature capable of this? Is it not possible that even the indefatigable Mr. Warburton should have changed his mind in the course of time, and that he may have formed the opinion that he has had quite enough of trouble with medical affairs, and of credit as much as he had any title to. It should not be forgotten neither, that he is now a regular senator—a Fellow of the University of London—while he still holds his shares and his proprietorship in the Gower-street College.

After such labours and such appointments, is it not natural that the honour-

able member should enjoy his “*ease in his inn*,” and trouble himself as little as possible in future with the perplexities of medical legislation? True, he is pledged to *report* on the mass of information gathered on that invaluable inquest at which he presided. But the whole of the evidence has not yet seen the light; a portion only of it has had that privilege, leaving behind all that relates to the profession in the provinces, and the education pursued in the provincial schools. Till this comes forth it would, of course, be premature to report: the evidence must first be laid, in its entire form, before the medical practitioners of the empire. To take this preliminary step Mr. Warburton has not yet had leisure,—which must be a source of considerable annoyance to him, as we happen to be aware of his having years ago promised several parties the almost immediate publication of their evidence; nor did the conflagration of both Houses of Parliament interfere to prevent his performing his promise.

By the way, we recollect the leveling part of the medical press about that time rang aloud the changes on the “providential” escape of the documents of the Committee: there would be no interruption of Mr. Warburton's labours; the evidence would be published; the report—the long-expected report, *diu multumque desideratum*—would appear in due time. How gratifying that the immense expense of time and money bestowed in collecting so splendid a mass of evidence did not go for nought, but that, as they said, we might still look forward with confidence to the sweeping changes to be effected by the member for Bridport, and the snug prospect of a “one Faculty.”

Patient waiters on Providence, what is it you any longer expect from Mr. Warburton? See you not the hon.

member comfortably settled in the council seat of the New University?—See you not his ill-disguised solicitude to become its MAJOR-DOMO, by procuring the place of *registrar* for a certain creature of his own?—And think you that he will pull down that house about his own ears, in order to set up for you a sort of “liberty-hall”? or that even if he would, he could, procure a charter for another establishment different from that which has been lately with so much difficulty obtained?

But in sober seriousness, what *has* become of the mass of evidence gathered from the lips of many of the most distinguished physicians and surgeons of Scotland, Ireland, and the provinces? Is this a time when such a heap of valuable information should remain in abeyance?—Now, when the constitution and character of the profession throughout the empire is subject-matter to be seriously considered in connexion with the yoke and brand which the Poor-Law potentates are endeavouring to fix upon it? Is this a time for such documents to be allowed to lie useless, as so much waste paper, while we are patiently to expect them hereafter when they come forth obsolete and flat? Will the *report* compensate us,—a report, of the possibility of constructing which we long ago expressed our doubts, and now entertain them more strongly than ever?

What report, we ask, can Mr. Warburton possibly draw up, having the least tendency to a remodelling of the medical grades, or levelling them all into one, when, in addition to his original position of proprietor and shareholder in the University College, he has accepted the appointment of a Councillor of the University of London; both establishments being recently chartered with his full concurrence? Let the honourable member for Bridport alone, when he has got into a comfortable

birth: *ibit qui zonam perdidit*, we doubt not, would be his reply, were he pressed on the subject, like that of the old soldier in Horace, who had got quite enough of warfare as soon as he stocked his purse. Had Mr. Warburton not succeeded in finding that “port” where he may “bid adieu to hope and chance,” we should have better expectations of his future exertions.

As it is, we despair of ever seeing a line of this once deeply-longed-for report, but which nobody now ever dreams of. Our despair is luckily not of a sombre cast; we are merely amused at the verity of our own predictions. Amusing, however, as may be the non-appearance of the report, it is otherwise in respect to the *evidence*; nor can we lay down our pen without once for all demanding to know why is not the *whole* of the medical evidence given to the public; for this is precisely the time, if ever, when its publication can be of any use?

DUTY OF THE MEDICAL CORPORATIONS

AT THE PRESENT CRISIS.

To the Editor of the Medical Gazette.

SIR,

YOUR correspondent Chirurgus, “who is manifestly in the councils of his order,” has taken some pains to convince your readers that the general practitioner, being placed between *two* stools, must inevitably come to the ground—that the natural relation between him and the medical corporations does not entitle him to look to either of them for protection and support; because—

“The child whom many fathers share,
Hath seldom known a father’s care.”

A gratifying announcement, truly!

There has long been, it must be confessed, a growing conviction in the minds of general practitioners, that such was the case; and recent events have forced the most moderate men to this unwelcome conclusion, and to the admission, that such a state of things urgently requires a remedy.

The College and the Hall had better look to this; the eyes of the profession are now upon them.

Stat sua cuique dies.

Why should either of these bodies waste any time in vain and fruitless disputes* with a pack of jesuits, on the literal meaning, or the spirit, of a clause relating to the qualification of medical officers? Could no better occupation be furnished? Have not all these bodies been officially and repeatedly informed, from respectable and authentic sources, of the injuries and insults received by their Licentiates from the Poor-law authorities? Do they doubt the representation of facts as notorious as the sun at noon-day; or have they no sympathy for men suffering such unmerited and intolerable grievances? Will they permit the profession to be deeply degraded, and its usefulness seriously impaired, without making one well-directed effort at resistance?

What they *will* do, remains to be seen. What they can do, has been stated. What they might and should do, you have properly indicated. Let us hope, then, they will arouse, at length, from their lethargy, and declare to the legislature, even in these dog-days of political economy, that the present system of medical relief to sick paupers is destitute of humanity, injurious to the community, and intolerably degrading to the profession.

Such a step must lead to the best results. It must command attention and ensure respect; it must raise the hopes and augment the efforts of the whole profession.

If, at any period, active union and cordial co-operation can be useful to the profession, now surely is the time. If it be desirable that one sentiment should animate the entire body of the profession, that sentiment should be—"He who allows oppression, shares the crime."—I am, sir,

Your very obedient servant,

A COUNTRY PRACTITIONER,
BUT NO SLAVE.

March 13, 1837.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, March 14, 1837.

DR. R. BRIGHT, THE PRESIDENT, IN
THE CHAIR.

Dr. Bostock on the Pathology of the Urine.

A PAPER was read containing some suggestions, by Dr. Bostock, of a plan for

* Vide 2d Annual Report of Poor-law Commissioners; Appendix C.

obtaining with greater precision a knowledge of the principal pathological conditions of the urine. The author adverts to the fact, that our knowledge of the changes in the chemical and physical properties of the urine, and of the relation which these bear to the morbid changes in the constitution, is less than might have been anticipated from the numerous experiments performed upon it. To obviate this defect, he suggests to practitioners to institute a series of what may be called statical experiments, made precisely in the same mode, and consequently admitting of direct comparison with each other. In the prosecution of this plan, an individual was selected, as the standard of comparison, of sound constitution and regular habits. The average healthy state of the urine of this individual was first ascertained, and afterwards the nature and amount of the occasional deviations, with the causes to which these were referrible. This object being first attained, we may compare this standard case with other individuals, noting the differences of constitution, habits, &c. The circumstances which the author has selected for experiment are the following:—External characters, including colour, odour, clearness, specific gravity, &c.; degree of acidity; presence and amount of albumen; amount of residuum after evaporation; proportion of this soluble in alcohol; amount of saline contents; of calcareous salts; and spontaneous changes. As a specimen of the tabular form, the author subjoins a synopsis of some experiments performed on the urine of the healthy individual, and also on that of the patient with exostosis, whose case was read at a late meeting.

A paper was then read, containing—

"A Description of two new Instruments,—the first for tying Polypi of the Uterus, Nose and Ear, and encysted Tonsils; the other for sewing together the edges of vesico-vaginal and recto-vaginal Fistulae. By William Beaumont, Esq., Surgeon to the Islington Dispensary."

The advantages attending the use of the former instrument, the author considers to consist in the greater facility of applying the ligature, in its exerting a greater power of constriction, and in its being capable of being removed as soon as the noose is tied, without any diminution in the degree of constriction. The author relates four cases—three of polypus in the meatus auditorius externus, the other in the nostril, in which he had operated with his instrument; in all, the relief remains complete as far as he is aware, and in the three former instances the hearing of the

patients was to a great degree restored immediately after the operations.

The paper was accompanied with diagrams of the several instruments; and the instruments themselves were exhibited and explained to the meeting by the author.

CLINICAL LECTURES,

DELIVERED AT THE

MEATH HOSPITAL AND COUNTY OF DUBLIN INFIRMARY,

During the Session 1836-7.

BY PROFESSOR GRAVES.

LECTURE VIII.

Glanders and Button-farcy in the human subject—Particulars of a case of Glanders, with the post-mortem appearances—Remark on the variety of Skin diseases produced by the introduction of an animal poison into the system—Case of Button-farcy—Analogous appearances, where, as in Typhus, an animal poison is sometimes generated in the body—Furuncular inflammation, or carbuncle, generated by animal poison—Also Tubercles—Sometimes a praternatural whiteness precedes the purple hue of mortification—Remarks on Phlegmasia dolens—Phlegmasia dolens of the Eye.

IN pursuance of my intention, as announced in a former lecture, I shall proceed to-day to the consideration of two affections resulting from animal poison, one of which has been but recently introduced to the notice of the medical profession; of the other, I am not aware that there are any published cases in existence. I allude here to glanders and button-farcy in the human subject.

The profession is chiefly indebted to the researches of Dr. Elliotson for the first accurate account of glanders in the human subject, a disease which has now excited a very large share of attention here and on the continent. Many other observations, published since Dr. Elliotson undertook the illustration of this disease, have established the fact, that the morbid matter secreted by horses labouring under glanders may communicate the infection to the human subject, and thus give rise to a loathsome, painful, and generally fatal disease. From the notices which I have been able to collect, it appears that glanders in man is of very frequent occurrence in Ireland—so frequent, indeed, that I think the legislature is called on to imitate the wise example of the Prussian government in placing glandered horses under the surveillance of the police.

Like many other animal poisons, that of glanders does not seem capable of affecting every individual indiscriminately;

indeed the average susceptibility must be small, for grooms and veterinary surgeons take few or no precautions in examining the diseased animals, and yet the proportion infected compared with the number exposed is by no means considerable. That such persons exhibit great carelessness in examining glandered horses, appears from the directions given in books on Farriery, "that the finger should be introduced into the nostrils for the purpose of ascertaining whether certain spots suspected to be ulcers are so or not." Now when the viscid gluey nature of the discharge from the nostril is taken into account, we cannot but conclude that this operation of introducing the finger into such a mass of vitiated and poisonous secretion would more frequently prove the means of infection, were the human constitution very susceptible of the poison, for we are to recollect that the fingers of such persons are seldom free from scratches and abrasions.

I shall now read the following case of glanders in the human subject. It is one of extreme interest, and has been most faithfully and graphically detailed. It occurred in the Richmond Hospital, and has been communicated to me by Dr. M'Donnell. You will find in it many points of resemblance to a series of cases translated from a German journal, and published in a late number of the Medico-Chirurgical Review.

Patrick Wallace, a healthy, muscular man, aged 20, was admitted into the Richmond Surgical Hospital on the 6th October, 1836. It was stated that he had been in care of a glandered horse, driving, cleaning, &c. and that he had been in the habit of drinking out of the vessel from which the horse drank. It appeared also that he had had an abrasion on one of his ears. On admission he had much of the appearance of a person labouring under cynanche tonsillaris: he could only open his mouth to the extent of half an inch; this was the only uneasiness complained of. The left tonsil was very much enlarged, red, hard, and projecting towards the middle line; no fluctuation could be felt. There was a general fulness about the angle of the jaw, extending upwards nearly as far as the zygoma. The submaxillary gland on the same side was also enlarged and indurated. These symptoms had been ushered in by feverishness, a few days previous to admission. He was ordered to have eight leeches to the throat, to be followed by a poultice, and a bolus composed of calomel and jalap.

Next day the external swelling was found to be increased; greater difficulty of opening the mouth; the tonsil still hard and swollen. Twelve leeches were applied to the fauces, and the patient took

the tartar emetic mixture of the hospital, with sulphate of magnesia.

On the 15th of October the disease is reported to be on the increase. Tonsil still hard, but no fluctuation; left side of the face greatly swollen; eye of same side nearly closed from tumefaction of the lids; general inflammatory appearance over the cheeks, and great hardness of the tissues about the angle of the jaw of the same side extending towards the chin; several circumscribed spots of redness, varying in extent from the size of a sixpence to that of a halfpenny, with irregular margins, scattered over different parts of the body. Two pustules observable on the left leg.

19th.—A vesicle containing a yellowish serum observable on the left tonsil; the same inability of opening the mouth continues; increase of swelling over the left side of the face; a small abscess has formed on the posterior part of the left forearm; some delirium during the night; three evacuations from the bowels. The tonsil to be brushed over with a solution of nitrate of silver; a blister to the fauces: the tartar emetic mixture to be continued.

17th.—Some sleep during the night, interrupted by delirium of a low muttering character. Patient appears willing to answer questions, but cannot, from obstruction in the mouth. This, however, lasts but for a moment, and he then lapses into a state of incoherency. Mouth open to the extent of half an inch; left eye closed; considerable swelling of the left side of the face, which is indurated, hot, tense, and shining; all the glands on both sides of the jaw, but particularly on the left, are swollen and hard; same state of tonsil; nares dilated; breathing stertorous, somewhat hurried, about 28 in the minute, and interrupted by frequent sighs. Pulse very small, rapid, intermitted, and cannot be counted; skin hot, tongue furred, teeth covered with sordes. He complains of great thirst, but says he feels no pain; it is evident, however, that he feels great uneasiness in the joints and limbs when moved. There is, however, no swelling or redness of the joints. There is no discharge from the nostrils, nor is there any perceptible ulceration of the mucous membrane of the nose. No apparent affection of the absorbent glands in any other part of the body.

During this period vesicles and pustules of various sizes and at various stages of growth had made their appearance on different parts of the body, particularly on the back. They varied in size from the head of a pin to the section of an almond. In the first stage they resembled very minute vesicles, scarcely surrounded by any inflammatory border, and containing a limpid serum. In the second stage, the serum was replaced by pus; there was a

considerable blush of redness around each pustule, which at this period became greatly increased in size. When one of the vesicles was punctured, the serum appeared to come from a single cavity under the cuticle; this operation did not produce any subsidence of the tumor, a considerable hardness still remaining in the cutis or beneath it, with a cavity in the centre in which the serum was contained. A number of *achores* existed in various parts, congregated together, and not much larger than the head of a pin. These clusters were surrounded by ~~the~~ raised margins, having much the appearance of wheals, and about a line and a half or two lines in breadth; between these margins and the *achores* there existed a line of redness. The whole taken together are rather of an oval shape. There also existed numerous inflammatory spots on the right shoulder, left arm, and other parts of the body. These were of a dark brown, approaching to a livid colour; when pressure is made on them the colour disappears, but returns immediately when it is removed. On running the finger over them a small hard tumor was felt in the centre: the margins of these spots were irregular.

On the 17th the character of the disease became more plainly developed: at 3 o'clock P.M. pus in considerable quantity was observed to issue from both nostrils. The patient was ordered to take the solution of chlorate of soda internally in drachm doses, three times a day, and also a mixture composed of carbonate of ammonia, liquor ætheris oleosus, and camphor mixture. At 5 o'clock P.M. he was found half out of bed, his head resting on the pillow; still able to express his wants; pulse not to be counted; legs and feet cold; breathing stertorous; numerous stigmata scattered over the surface of the body. The purulent discharge from the nostrils has ceased, but there is a discharge of mucus from the mouth, with considerable *stertor* of breath.

8 o'clock P.M.—A copious perspiration has broken out over the body; face red, tense, shining, and very much swelled: swelling has now extended to the right side of the face; right eye nearly closed; can open the left better; a few pustules have made their appearance at the inner canthus of the eye. Pulse, tongue, and skin, as in last report; delirium and muttering continue.

Died at 4 o'clock A.M. October 18th.

On examining the body ten hours after death, the redness was found to have disappeared from the face; the glands about the left angle of the lower jaw as before mentioned: they were found matted to the surrounding parts. The cellular tissue covering the submaxillary and parotid

glands was infiltrated with serum, and indurated; numerous depositions of pus were found in the tissue of the submaxillary and parotid glands. The brain was firm, but its ventricles contained a considerable quantity of fluid; the arachnoid membrane was opaque in many places; several patches of vascularity were observed on the pia mater. The lungs presented a congested appearance; numerous pustules were scattered over their surface, some separate, yellow in the centre, and surrounded by an ecchymosed border, others existing in clusters. They resembled in every respect those found on the surface of the body. The lining membrane of the larynx was very much inflamed, especially about its upper part and about the epiglottis. The inflamed parts in this situation were of a livid hue. There was some appearance of vesicles in the trachea, but this could not be satisfactorily ascertained. The bronchial tubes were filled with mucus. The stomach contained a quantity of yellowish green mucus; its lining membrane presented an ecchymosed and inflamed appearance. The liver was somewhat enlarged, and adhered by its inferior margin to a few folds of intestine. The periosteum did not exhibit any appreciable deviation from the normal state.

One of the chief things to be noticed in the foregoing case is the variety of inflammatory affections observed in the skin, as the result of the introduction of an animal poison into the system. There was in the first place the general diffused redness of the face, then superficial inflammatory spots on the shoulders and arms resembling erythema nodosum; in the next place, scattered pustules of various sizes, commencing in the form of a vesicle, which afterwards became a pustule surrounded by an inflammatory zone; and lastly, *achores* congregated together and surrounded by an elevated white margin, within which there existed an inflammatory ring of a red colour. Another point worthy of notice is the state of the lungs and bronchial mucous membrane. The lining membrane of the larynx, particularly in the vicinity of the epiglottis, was inflamed and of a livid colour, and there was an indistinct appearance of vesicles in the trachea. But what was particularly deserving of note in the lungs, was the existence of pustules on their surface, bearing the closest resemblance to those found on the surface of the body. It is not stated whether there was any appearance of vesicles or pustules in the nose, pharynx, or oesophagus, but we are told that the stomach was ecchymosed and inflamed.

The following case was witnessed by myself and Dr. Halahan, and seems more

nearly allied to the variety of glanders termed button-farcy. I regret that want of time has prevented me from arranging its details in a form more worthy of your attention, and were not the disease one of comparatively rare occurrence, I should not have ventured to lay the case before you in its present imperfect state.

The subject of this case was a gentleman residing at Rathmines, an extensive proprietor of horses, and who, having originally graduated as a surgeon, exhibited much skill in the veterinary art. About the time of his illness he had had some horses in his establishment labouring under glanders and button-farcy, to which he paid particular attention. After having laboured for some days under considerable lassitude and derangement of the stomach and bowels, he was attacked on the 8th of July with rigors, followed by great thirst, excessive heat of skin, and pains in his limbs. The moment he felt himself attacked in this way, he said he was sure that he had got some dangerous infection from the horses, and would never recover. He took some blue pill and colocynth, which produced a few dark and very foetid evacuations. On the 9th, his pulse was 94, his urine very high coloured, his thirst and feverish symptoms rather increased, and he suffered greatly from constant nausea and vomiting. A tumor now began to appear about three inches above the inner ankle of the right foot. He applied a poultice over it, but was obliged to remove it in a short time in consequence of the pain occasioned by its weight. The tumor was about the size of half a walnut, of a dull red colour, tense, shining, and exquisitely painful. Its external aspect was peculiar, and might be compared to something intermediate between a boil and a spot of erythema nodosum. On the 10th, another tumor of the same character appeared near the outer ankle of the same leg; and in this way the disease went on, tumor after tumor appearing on different parts of the body, with an increase of the feverish symptoms, until the 20th of July, when he was first seen by Dr. Halahan. At this time several tumors had appeared on different parts of his body; there was one of an extremely painful character on his head, and he complained of great tenderness and pain along the right clavicle. His thirst was still urgent; his restlessness excessive; the slightest motion gave him exquisite pain, and sleep had completely abandoned him. He had endeavoured to regulate his bowels by purgative medicines, and had applied leeches to the tumors and to the clavicle at various times, but without any decided benefit. There were eight or nine tumors on different parts of the body, of the cha-

racter before mentioned, without any tendency to suppuration, and so exquisitely painful that he could only bear a single sheet over him. The inflammation about the clavicle, which was of a diffuse character, had extended up the neck and over the right shoulder; there was not much swelling except about the clavicle; the colour of the affected parts was a peculiar dusky red. Immediately over the clavicle two vesicles were observable, filled with a transparent fluid. Three dozen leeches were ordered to be applied over the clavicle and shoulder, and the patient was directed to use chicken-broth, beef-tea, and other light nutritious articles.

On the 21st, all symptoms are stated to be on the increase. His fever, thirst, and sleeplessness, are undiminished; his tongue furred and dry; his teeth covered with sordes; his pulse small, weak, and rapid; his nausea and vomiting not so troublesome. He had received no benefit from the application of the leeches; the swelling and stiffness of his neck was increased, and he had now some difficulty of swallowing. The erysipelatous surface of the neck, clavicle, and shoulder, were lightly brushed over with lunar caustic, which gave the patient an agreeable sensation, and from which he stated that he derived much relief. This was repeated the next day at his own request, and with equal benefit; the difficulty of deglutition diminished, and for two days he went on pretty well. On the 25th, there was an evident increase of fever; the tumors over the body and limbs were increasing in size and number; and his anxiety, restlessness, and sufferings unabated. He had taken alterative doses of calomel and James' powder, and his bowels had been regulated by mild aperients and enemata. I saw him for the first time on the 28th. His pulse was then 98, small, and easily compressed; his thirst excessive; his restlessness and agony such as would strongly excite the pity of persons most conversant with scenes of human suffering. He had several tumors over different parts of his body, all exquisitely painful, and in their aspect something between boil and erythema nodosum. Some of them were hard to the touch, others which appeared more advanced, were softer, and had a boggy feel. There was however, no appearance of any thing like suppuration. He was ordered sulphate of quinine, chicken broth, &c, and other light nourishment, and an opiate at night. On the 31st, a tumor appeared on the right side of his forehead, larger and more painful than any of the rest. Another of a similar character showed itself on the right clavicle, which had been previously affected. Shortly after their appearance, vesicles

were observable on their surfaces, such as generally precede mortification in cases of anthrax and malignant carbuncle. Next day he was evidently worse: his pulse was 106, his fever, pain, and restlessness unabated; and a miliary eruption began to make its appearance over his chest and abdomen. The vesicles now began to increase on the surface of the tumor, his fever and restlessness were aggravated, and his mind, which had been hitherto collected, began to wander. His restlessness was so excessive that he could not remain for a moment in the same position, and being a person of much mechanical ingenuity, he had a set of pulleys constructed and fastened to his bedstead, so that he could move himself in various directions. His medicines and diet, with the addition of claret, and opiates at night, were continued as before.

On the 6th of August he was still worse; the tumor on the head continued to enlarge, and decided sloughing had taken place. The tumor on the clavicle presented the same aggravation in appearance and character, and a fresh tumor had appeared on the back of his head. A pustular eruption now began to make its appearance over his body, chiefly over the abdomen and limbs, his symptoms became aggravated in every respect, the delirium and watchfulness increased, and he died on the 10th of August, about thirty-three days from the commencement of the disease. He attributed his illness to attending horses, four of which had died of button-farcy; and what is also curious, his nephew, who had also been engaged about the diseased animals, had fever of a typhoid character, with petechiæ of a larger sort than usual, but ultimately recovered.

The symptoms of glanders in the human subject have been so fully detailed by Dr. Elliotson and others, that it only remains for me to make a few observations connected with this subject. In the first place it may be observed that most diseases produced by the deleterious effect of animal poisons on the economy show a tendency to cause not only fever often of a malignant character, but also various forms of external disease, chiefly limited to the superficial glands, subcutaneous cellular tissue, and skin. In urticaria, small-pox, and measles, the external disease is chiefly limited to the skin: in scarlatina, we have often swelling of the parotid gland, with infiltration of the adjacent cellular tissue in addition to the cutaneous eruption: in syphilis and cases of dissecting wounds, we have disease of the skin frequently combined with an affection of the superficial lymphatic glands. The same observation applies to typhus, many cases of which are characterized by an eruption of

spots over different parts of the body, or by the occurrence of what are termed petechiæ. On these matters I need not enlarge, as you are all well acquainted with them, but that vesicles and pustules very similar to those observed in dissection wounds, and other diseases produced by the direct introduction of animal poison into the system, may arise from the action of morbid changes spontaneously occurring in the body, is a fact which admits of being proved, and opens to us a new and interesting field of inquiry. Thus, in cases of typhus, where the effect of pressure or some other accident has occasioned bed-sores of a bad character, and even where there are no bed-sores present, I have on several occasions seen low secondary fever produced, and have observed vesicles or pustules appear on the skin, similar to those described by Mr. Colles as accompanying the fever of dissection wounds. An example of this occurred some time ago at this hospital, and you have recently witnessed another in the case of a young man recovering from typhus. It might be argued that the secondary fever and eruption in such cases arise from the absorption of morbid matter into the system, and I am willing to admit that there is some colour of argument for this statement where the patient labours under bed-sores of a bad and gangrenous character, but that this explanation is not the true one appears from the case of the young man to which I have alluded. He had no bed-sores to account for the secondary fever and eruption; and we can only explain by supposing that it is the result of a poison generated in the system during the course of fever. This is particularly deserving of notice, as I am not aware that any author on typhus has noticed this symptom, or pointed out the circumstances under which it occurs. The same phenomenon is occasionally observed where, in consequence of external injury, diffuse cellular inflammation has taken place. Thus, several years ago, a woman was admitted into the Meath Hospital, who had diffuse cellular inflammation in consequence of receiving a kick on the chest. After a few days, Colles's pustules appeared on different parts of the body, and she died with symptoms of croup. On dissection, the croupy symptoms were found to depend on an eruption of vesicles filled with opaque serum, over the lining membrane of the larynx and trachea. Something analogous to this was observed in the case of Wallace; and the coincidence is further strengthened by the frequent occurrence of disease of the lining membrane of the larynx and trachea in many other febrile affections accompanied by cutaneous eruption, as small pox, measles, syphilis, and scarlatina.

Another point which is deserving attention with reference to the phenomena of external disease in cases where animal poisons have been generated in the system, or arisen from infection, is the occurrence of tumors in different parts of the body partaking of the characters of furuncular inflammation or carbuncle, and running through a somewhat similar course. These tumors formed a very prominent feature in the case of Wallace; and in the gentleman who laboured under button farcy, they constituted one of the most important symptoms of the disease. We also observe something similar to this in that form of venereal which Mr. Carmichael terms tubercular, and which is characterized by the appearance of small, hard, dark red tumors, on various parts of the body, which exhibit a very imperfect tendency to suppuration, and frequently give rise to sores of a bad and unfavourable character. Another circumstance observed in Dr. M'Donnell's case deserves some share of attention; I allude to the white elevated margins, like wheals, around the redness which more immediately encircled each cluster of aches, and which we are to look upon as in a less advanced stage of its progress, being as it were only the first stage of the latter. It is a curious fact that on many occasions a preternatural degree of whiteness precedes the redness and congestive purple hue which ushers in mortification. This is generally known in the case of the nose when frost-bitten, and which always appears preternaturally white in the commencement. Something analogous to this was observed in some cases of bad typhus treated here in 1826 and 1827. The nose sometimes assumed a peculiar white colour, and not unfrequently exhibited a tendency to mortification. When first seen it had a preternatural whiteness, and looked very like a nose made of white wax; in the course of a few hours it changed to a purplish red, and exhibited symptoms of approaching gangrene. Again, in urticaria, we often see some portions of the inflamed skin assume a white colour, and the same occurrence may be noticed likewise in the wheals caused by nettles or the stings of bees. In general we connect the idea of integumental inflammation with the appearance of redness, and this phenomenon is explained on the hypothesis that a preternatural quantity of blood is circulating in the inflamed parts. How then are we to account for the facts I have mentioned? To what cause are we to attribute the co-existence of increased vascularity, and a remarkable whiteness or pallor of the parts? a state displayed in a very remarkable manner in *phlegmasia dolens*. I think the explanation is not very difficult when we recollect that the capillary vessels of

LECTURES

ON

MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

By JON. PEREIRA, Esq., F.L.S.

LECTURE LIX.

I PROPOSE to commence, in this lecture, the examination of

LEGUMINOSÆ, OR FABACEÆ,

one of the largest, and, in point of structure, one of the most natural families of the vegetable world; and one also which offers many points of interesting inquiry.

Botanical characters.—Leguminous plants present themselves under three forms; some are herbaceous, some are shrubby, while others form large trees. The leaves are usually alternate, with stipules, often compound, and in some instances, as in *Mimosa pudica*, are very irritable. The flowers are usually bisexual, rarely polygamous, or dioecious. The calyx is five-parted, toothed or cleft, inferior, with the odd segment anterior. The petals are five, or by abortion, four, (rarely less than this number, or wanting) inserted into the calyx or torus. A considerable number of the plants of this family have papilionaceous flowers; the large upper petal of which forms the *vexillum* or *standard* ; the two lateral ones are called *alæ* or *wings* , while the two lower ones are united by their margins, forming what is called the *carina* or *keel* . Although all leguminous plants have not this kind of flower, yet all plants with papilionaceous flowers belong to this family. The stamina are usually

486.—XIX.

FIG. 161.—*Papilionaceous flowers.*

(not invariably) ten in number, and they may be distinct, monadelphous, diadelphous, or occasionally, though rarely, triadelphous. The ovarium is simple, superior, one-celled, with a simple style and stigma. The fruit is either a legume or a drupe.

FIG. 162.—*Legumes of Ceratonia Siliqua.*

The term *leguminosæ*, used to designate this order, is evidently objectionable, since all the plants have not leguminous fruit; and, on the other hand, all plants which have leguminous fruit do not belong to this order, for some *Amyridaceæ* have legumes.

The seeds are (with one or two exceptions) destitute of albumen: the embryo

3 P

is either straight, (*rectembriae*) or the radicle is bent on the cotyledons (*curvembriae*).

FIG. 163.—Common garden bean.

- a, Plumule.
b, b, Cotyledons, or seed lobes.
c, Radicle bent on the cotyledons (*curvembriae*).

Division.—Decandolle thus sub-divides this extensive family into four sub-orders.

Legumi- nosae.	{	Curvembriae.	{ 1. Papilionaceae
			{ 2. Swartziaceae.
			{ 3. Mimosaee.
	{	Rectembriae.	{ 4. Cæsalpiniee.

Properties.—Notwithstanding the remark already made, that with regard to structure, leguminosae form one of the most natural families of the vegetable creation, yet it must be confessed that, considered with reference to their chemical, dietetical, and medicinal properties, they offer little uniformity. To illustrate this, we may compare the properties of similar organs (seeds, for example) of different leguminosae: and we shall find that some are valuable articles of food, as peas and beans; while others are medicinal, or even poisonous. Thus the seeds of *Spartium junceum* in small doses are diuretic, in larger ones, emetic and purgative; and in some other instances we find leguminous seeds having a specific influence over the nervous system: for example, the seeds of *Cytisus laburnum* are narcotico-acrids, or in some cases almost pure narcotics. Five grains of *Cytisine*, the active principle of these seeds, act as powerfully as three grains of tartar emetic; eight grains acted on Chevallier in a very alarming manner. Bread made of flour containing the seeds either of *Lathyrus cicera* or *Ervum ervilia* has in several instances operated in a poisonous manner, giving rise to paralysis or convulsions.

Even plants of the same sub-order will hardly admit of comparison. Thus among *Papilionaceae* we find nutrients, demulcents, tonics, astringents, emetics, purgatives, diuretics, narcotico acrids, and pure narcotics. *Cæsalpinieae*, for the most part, possess purgative properties, yet with many exceptions; and so with respect to *Mimosaee* (from the stems of

which we obtain gum and astringent matters), substances of varied properties are procured.

SUB-ORDER.—PAPILIONACEAE.

Spartium junceum.

History.—Theophrastus and Dioscorides speak of a plant which they call *σπάγρον*, or *σπάγρον*, which was probably what Pliny terms *Genista*, though the Roman historian was himself doubtful on this point. The plant referred to is commonly supposed to be the *Spartium junceum*, or Spanish broom, which, according to Dr. Sibthorp, is now termed in Greece, *σπάγρον*.

Botanical characters.—Spanish broom is a deciduous shrub, a native of the south of Europe, having opposite round branches, flowering at the end, leaves lanceolate, but few in number, papilionaceous yellow flowers, in terminal racemes, stamens monadelphous, legumen plano-compressed, many-seeded, glandless.

FIG. 164.—*Spartium junceum*: Spanish broom.

In the Linnean classification, this plant belongs to class *Diadelphica*, order *Decandria*.

Physiological effects.—The seeds are emetic and purgative in large doses, and diuretic in smaller quantities. The two first of these effects are stated by Dioscorides to be those of *σπάγρον*. Dr. Pearson calls broom a tonico-diuretic, since it improves the appetite, and invigorates the whole system.

Uses.—They have been employed by Dr. Eccles, of Birmingham, in dropsical cases. Their advantage over other diuretics is their tonic operation, in consequence of which they may be persisted in for an indefinite length of time.

Administration.—The best method of exhibiting these seeds is in the form of tincture, prepared at the Birmingham hospi-

tal, of two ounces of the bruised seeds to eight ounces of proof spirit. The dose of this preparation is from one to three drachms. The *powder* of the seeds may be taken to the extent of ten or fifteen grains three times a day, in cold ginger tea, or mint water.

Cytisus scoparius.

History.—Some have fancied that the *σταγθιον* of the Greeks was our common broom, (*Cytisus scoparius*), but it is much more likely to have been Spanish broom (*Spartium junceum*) as already mentioned. Common broom is termed in some botanical works *Spartium scoparium*, in some, *Genista scoparia*, in others, *Cytisus scoparius*.

Botanical history.—This indigenous shrub grows in great abundance in dry gravelly thickets and fields. It is from three to six feet high. Its branches are numerous, long, straight, angular, smooth, and green: the leaves are ternate, stalked, the upper ones simple, the leaflets oblong. The papilionaceous flowers are axillary, stalked, large, of a bright yellow colour: calyx two-lipped; standard large and broad, ovate, keel blunt: stamina ten, connected at the base, and, therefore, really monadelphous, though the Linneanists place this plant in *Diadelphia*: pistillum solitary. The legume is flat, hairy at the margin, and contains fifteen or sixteen seeds.

In the Linnean classification, it is placed in class *Diadelphia*, order *Decandria*.

Officinal.—The fresh tops of this plant are officinal in the new London Pharmacopœia: they have a bitter nauseous taste, and when bruised, a remarkable odour.

Chemical properties.—Cadet de Gassicourt has analysed the flowers of this plant, but I am not acquainted with any analysis of the stems or leaves.

The ashes of the plant contain carbonate of potash, which, when procured from this source, is termed *salt of broom*, or *sal genistæ*. Hill says, a pound of the green twigs of broom, with the leaves and flowers, yields a drachm and a half of this salt. Hence, therefore, some vegetable salt of potash exists in broom, and which, by incineration, is converted into the carbonate.

Physiological effects.—(a). *On animals generally.* In some part of Europe broom is employed as winter food for sheep; and Withering says that it prevents the disease called rot, and is salutary in dropsy, to which sheep are liable. According to London, it is apt to produce disease of the urinary organs,—to prevent which, some recommend the plentiful use of water.

(b). *On man.* Broom has been celebrated as a diuretic by Mead, Cullen, and others. "Though very little in use," says

Dr. Cullen, "I have inserted this in my catalogue from my own experience of it. I found it first in use among our common people; but I have since prescribed it to some of my patients in the manner following:—I order half an ounce of fresh broom tops to be boiled in a pound of water till one-half of this is consumed, and of this decoction I give two table-spoonfuls every hour, till it operates by stool and urine; and by repeating this exhibition every day, or every second day, some dropsies have been cured." Having very frequently employed broom in dropsies, I can add my testimony to its powerful effects as a diuretic. I cannot call to mind a single case in which it has failed to act powerfully on the kidneys. In some cases it produced a most marked and beneficial effect on the dropsical effusion. According to my experience it is the most certain of all diuretics in dropsies. In large doses, broom is emetic and purgative.

Uses.—It has been principally or solely employed in dropsies, and, as already mentioned, sometimes with great benefit. Of course its chance of cure depends on the nature of the cause of the dropsical effusion. I am not aware of any contraindications to its use, though it is not improbable that it might be prejudicial in inflammatory cases, or dropsy depending on diseased kidney.

Administration.—The infusion of broom of the Pharmacopœia is prepared with an ounce of broom and a pint (20 ounces) of water. The simple decoction may be prepared in the way recommended by Dr. Cullen. There is a compound decoction in the London Pharmacopœia: it is composed of broom, juniper berries, and root of dandelion, of each half an ounce, water a pint and a half (30 ounces): boil down to a pint. The dose of all these preparations is one or two ounces. The extract of the Dublin Pharmacopœia is given to the extent of half a drachm or a drachm. The seeds of *Cytisus scoparius* may be given in tincture or powder, as *Spartium junceum*. Dr. Pearson remarks "broom-seed is not adapted to thoracic dropsy, especially when that form of dropsy is combined with pulmonary congestion, or with any degree of inflammatory affection of the chest."

Glycyrrhiza glabra.

History.—The *γλυκυρρίζα* of Hippocrates and of Dioscorides are doubtless identical; the latter is supposed by Sprengel and others to be our *Glycyrrhiza glabra*, by Dierbach to be *G. glandulifera*, but by Dr. Sibthorp it is said to be the *G. echinata*, which is now termed in Greece *γλυκόριζα*.

Botanical characters.—*Glycyrrhiza glabra* is a native of the south of Europe. It is a perennial plant, with an erect, smooth

stem, four or five feet in height. The leaves are pinnate, with a terminal leaflet: the leaflets are ovate, blunt, petiolated, of a yellowish-green colour, clammy on the under side. There are no stipules. The inflorescence is a pedunculated raceme (Decandolle calls it a spike.) The papilionaceous flowers are bluish or purplish. The fruit is a smooth, oblong, three or four-seeded legume. The Linnean class of this plant is *Diadelphia*, and the order *Decandria*.

Officinal.—The officinal part is the root, or rather the underground stem (*rhizome*), commonly termed in the shops *liquorice root*, and which has been latinized into *radix liquiritiæ*. Its physical properties are too well known to need description.

Extract of liquorice.—By boiling the roots (or rhizomes) in water (generally in copper vessels), and evaporating the decoction, we obtain an extract called in the shops *liquorice juice*, or, according to the countries from whence it is brought, *Spanish* or *Italian juice*. In Spain it is said to be procured from the roots or underground stems of *G. echinata*. It occurs in cylindrical or flattened rolls, of five or six inches long, and about one inch in diameter. When pure it is black and dry, with a shining fracture, and a sweetish taste: it is completely soluble in water. As met with in commerce, however, it is rarely pure. Neumann obtained 460 of watery extract from 480 of Spanish liquorice. It contains the soluble principles of the root, with some copper scraped off from the boiler by the spatula employed to stir the extract during its preparation. Féc says that four pounds of this extract yield two drachms and a half of metallic copper; but I suspect there must be some exaggeration in this statement. Several preparations of refined liquorice are kept in the shops: one is sold in a pipe form, (*pipe*, or *refined liquorice*) which is an inferior substance, a second is the Pontefract lozenges, and a third has been recently introduced under the name of quintessence of liquorice.

Composition.—Two analyses of liquorice root have been made: one by Robiquet, another by Trommsdorf. The constituents, according to the first of these chemists, are—

Wax.

Acrid soft resin.

Asparagin (Desvaux's *Agedöite*).

Glycyrrhizin (Glycion).

Starch.

Ligneous fibre.

Brown nitrogenous substance.

Albumen.

Malates, phosphates, and sulphates of lime and magnesia.

The substance termed *Glycyrrhizin*, or

liquorice sugar, is remarkable for its tendency to form difficultly soluble compounds with acids. It is not susceptible of the vinous fermentation.

Physiological effects.—Liquorice root and its extract are emollient, demulcent, and nutritive.

Uses.—The powder of the root is employed in the preparation of pills, either to give them a proper consistence or to prevent their adhesion. The decoction is employed as an emollient in irritation of the mucous membranes,—especially in catarrh,—and as a vehicle for the exhibition of other medicines. There is a formula for its preparation in the Dublin Pharmacopœia. On account of its emollient properties and saccharine taste, the root enters into several officinal preparations—as the compound decoction of barley, compound decoction of sarsaparilla, compound infusion of linseed, &c.

The extract of liquorice is employed in the form of lozenges, to allay tickling cough. It is also used to cover the unpleasant flavour of certain substances—as of aloes, in the compound decoction of this substance.

Tephrosia Apollinea.

The leaves and legumes of this plant are frequently found in Alexandrian senna.

Astragalus verus.

History.—Dr. Sibthorp tells us that the *τραγάκανθα* of Dioscorides, and of the modern Greeks, is the *Astragalus aristatus*, the gum from which is a species of tragacanth annually sent to Italy.

Botanical history.—The tragacanth of commerce is the produce of several species of *Astragalus*. Tournefort says that on Mount Ida, in the Island of Crete, it is procured from *A. creticus*; on Mount Lebanon, in Syria, the *Astragalus gummifer* yields it, according to La Billardière; while in Asia Minor, Armenia, and Northern Persia, Olivier tells us it is procured from *Astragalus verus*.

Astragalus verus is a small shrub, not more than two or three feet high, with a stem about an inch in thickness. The branches are covered with imbricated scales and spines, the remains of former petioles. The leaves are pinnate, composed of from six to eight pair of opposite, small, pointed, villous leaflets. The yellow papilionaceous flowers are axillary.

Astragalus gummifer has leaves composed of from four to six pair of oblong, linear, smooth leaflets. The flowers are from three to five, axillary, sessile. The pod is woolly.

In *Astragalus creticus* the leaves consist of from five to eight pair of oblong, acute,

tomentose leaflets, with axillary sessile flowers.

FIG. 165.—*Astragalus creticus*.

The Linnean class of the genus *Astragalus* is *Diadelphia*, the order *Decandria*.

Production.—Tragacanth is a natural exudation from the stem of the before-mentioned plants. The cause of the exudation of this as of other gums, is thus explained by Decandolle. The gummy matter of the stem resides in the bark and albumen; it is the nutritive juice of the plant; and its escape, therefore, is analogous to hæmorrhage in animals: hence plants in whom it spontaneously occurs are always in a sickly state. The mechanical cause of the expulsion of this juice is dependent on the unequal hygrometric properties of the different parts of the stem. The wood absorbs more moisture from the air than the bark, and hence it swells more. In consequence of its enlargement it distends the bark, which, by the internal pressure of the wood, gives way, and the gummy matter escapes. This explanation is quite in conformity with the facts mentioned by La Billardiére,—that tragacanth flows only in abundance during the night, and a little after sunrise. A cloudy night, or a heavy dew, is, he thinks, necessary for its production; for the shepherds of Lebanon only go in search of this substance when the mountain has been covered during the night with thick clouds.

Varieties and physical properties.—Two kinds of tragacanth are met with.

(a.) *Flaky Tragacanth*: *Smyrna Tragacanth* (Martius): *Tragacanth of the Astragalus verus?*—This is the tragacanth usually found in English commerce. It occurs in moderately large, broad, thin pieces, marked with arched or concentric elevations.

(b.) *Vermiform Tragacanth*: *Morea Tragacanth* (Martius): *Tragacanth of the Astragalus creticus?*—This variety is rarely met with in this country, but is common on the continent. It occurs in small, twisted, filiform, spiral pieces. There is more starch in it than in the first variety.

Both sorts occur of a white, yellowish, or yellowish-brown colour. Both are hard, tough, odourless, tasteless, very slightly soluble in water, though they swell considerably in this liquid, forming a thick tenacious mucilage. The fracture is dull and splintery.

Chemical composition and properties.—The following is the ultimate analysis of dry tragacanth, according to Hermann:—

Carbon	40.50, or 10 atoms = 60
Hydrogen . .	6.61, or 10 atoms = 10
Oxygen	52.89, or 10 atoms = 80
	100.00
	150

With respect to the proximate analysis some difference of opinion exists among chemists. According to both Bucholz and Guerin, tragacanth consists of a gum soluble in water, analogous to gum arabic, and, therefore, called *Arabine*; and a gum insoluble in water, analogous to gum bassora, and, in consequence, termed *Bassorine*.

	Bucholz.	Guérin.
Arabine	57	50
Bassorine	43	33
Water and oxalate lime . . . }	—	14
	100	100

Starch is also a constituent of tragacanth; the quantity, however, is small. It is recognizable by iodine.

According to Guibourt, tragacanth contains neither arabine nor bassorine, but is essentially formed by an organized gelatiniform matter, very different to gum Arabic both in its physical and its chemical properties, and which swells and divides in water, so as in part to pass through a filter. The insoluble part of tragacanth is, according to the same authority, a mixture of starch and lignin, which has nothing in common with bassorine. Decandolle suggests that the insolubility and swelling of tragacanth in water may arise from the gummy matter being contained in cells.

Mucilage of tragacanth is precipitated by alcohol, subacetate of lead, protochloride of tin, protonitrate of mercury, and infusion of galls. Oxalate of ammonia indicates the existence of a calcareous salt.

Physiological effects.—Tragacanth is emollient, demulcent, and nutritive.

Uses.—The powder of tragacanth is used rather as a vehicle for active and heavy medicines, than on account of its own

proper effects. Mixed with gum Arabic and starch, it constitutes the *compound powder of tragacanth* of the Pharmacopœia. *Mucilage of tragacanth* may be employed as an emollient in irritation of the mucous membranes. It is likewise used for the suspension of other substances.

Mucuna pruriens: Cowhage.

This plant, called by Linneus, *Dolichos pruriens*, by Persoon, *Stizolobium pruriens*, is a native of the East Indies, and perhaps also of the West Indies. Its root is perennial and fibrous; its stem is herbaceous and climbing, rising to a considerable height by twisting round the neighbouring trees. The leaves are ternate, stand upon long foot-stalks, and are placed alternately at the distance of a foot from each other. The papilionaceous purple flowers are in racemes. The fruit (called in the shops *siliqua hirsuta*) is an oblong pod, shaped like the letter *J*, four or five inches long, covered with brown bristly hairs (the *setæ siliquæ hirsutæ* of the shops), and containing from four to six seeds, of a brownish colour. In the Linnean classification the plant belongs to class *Dicladophia*, order *Decandria*.

The officinal part of the plant is the hairs of the pod. They have been celebrated for their anthelmintic properties. The best mode of exhibiting them is in treacle, syrup, or honey. The quantity of hairs should be sufficient to give the syrup, or treacle, the consistence of honey, or of an electuary; and of this mixture a tea-spoonful may be given to children, and a table-spoonful to adults: this dose should be taken twice a day—namely, at going to bed, and in the morning, an hour before breakfast. Chamberlaine says it usually operates more effectually where a gentle emetic has been premised. After continuing the electuary for three or four days, a brisk purgative of jalap, or senna, should be taken, which will in general bring away the worms. This remedy has been principally celebrated for the expulsion of the large round worm (*Ascaris lumbricoides*), and the small thread-worm (*Oxyuris vermicularis*). It is not equally serviceable against the tape worm.

The action of the hairs is thought to be mechanical—that is, they are supposed to pierce and torment these parasites, and thereby to oblige them to let go their hold. In support of this explanation, Mr. Chamberlaine tells us he sprinkled some of the hairs in a calabash full of very large round worms (*Ascaris lumbricoides*), and that in a little time the animals began to writhe and twist about, evincing thereby extreme torture. On examining them with a magnifying glass, the hairs were

found sticking loosely in various parts of their bodies.

The intolerable itching caused by the contact of these hairs with the skin, is also referrible to their mechanical operation. Their want of action on the internal coat of the intestines is ascribed to the mucous secretion which defends the subjacent membrane from injury. In one case, diarrhœa followed the use of a very large dose of the electuary, and in another instance enteritis came on, after taking this preparation once; but it is not certain that these were the consequences of the operation of the hairs.

Mucuna urens.

This is a native of the West Indies. The hairs on the outside of the pods are used as a vermifuge, like those of the last mentioned species. The pods are distinguished by their transverse lamellæ. The seeds are called *Yeur bourrique*, or *assè's eyes*.

Butea frondosa.

It is probable that this tree yields one kind of Catechu, termed, by the French, "*Cachou en masse*," or "*Cachou lûide*." The grounds for this opinion are, 1st, that from natural fissures and wounds made in the bark, there exudes during the hot season an astringent juice, which soon hardens into a ruby coloured, brittle, astringent gum, which has been confounded with kino; 2dly, that the kind of Catechu before alluded to, is imported enveloped in leaves, which Professor Guibourt has ascertained to be those of *Butea frondosa*; and lastly, that this kind of Catechu is not obtained from either *Acacia Catechu* or *Nauclea Gambir*, since the astringent extracts of these trees possess very different physical properties, as will hereafter be shown. In deciding on the validity of these circumstances, we ought also to take into consideration the fact that the *Butea* being a common tree in India, and its leaves being large, they might be employed to envelop the extract of other trees, whose leaves were not sufficiently large for the purpose.

I propose to notice all the varieties of Catechu when we speak of the tree mentioned in the Pharmacopœia as yielding Catechu—namely, *Acacia Catechu*.

Butea frondosa is a middling-sized tree, common in Bengal and in the mountainous parts of India. The leaves are alternate, petiolated, ternate, from eight to sixteen inches long; the leaflets are emarginate, or rounded at the apex, the pair obliquely oval, the exterior one obovate. The papilionaceous flowers are in terminal racemes; their colour is deep-red, shaded

with orange and silver-coloured down. The legume is pedicelled and pendulous.

FIG. 166.—*Butea frondosa*.

In the Linnean classification, *Butea* belongs to class *Diadelphis*, order *Decandria*.

Pterocarpus santalinus.

This tree is a native of Ceylon and Comorandel. It belongs to class *Diadelphis*, order *Decandria*, in the Linnean classification. Its leaves are ternate, with subrotund smooth leaflets; the flowers are in axillary racemes.

The wood of the stem is the red saunders' wood, the *lignum santali rubri* of the shops. It is imported in angular billets, blackish externally, but of a blood-red colour internally: it is compact, heavy, and of a fibrous texture.

The colouring matter of the wood is of a resinoid nature, and is termed *santalin*. It is hardly soluble in cold water, more soluble in boiling water; very soluble in alcohol, æther, acetic acid, and alkalies. It is almost insoluble in the fixed and volatile oils; the volatile oils of lavender and rosemary excepted.

This wood is employed in medicine only as a colouring agent. Thus it is one of the ingredients of the compound tincture of lavender.

Pterocarpus Draco.

This tree is said to be the source of what has been termed American or Carthagena Dragon's blood.

Pterocarpus erinaceus.

This plant is erroneously inserted in the London Pharmacopœia, as the source of the kino of the shops. Kino is now brought to us from Amboyna; whereas this tree is a native of Senegal. In some works there is an African kino described, which is said to be the produce of this species of *Pterocarpus*.

In the warehouse of an old drug firm in London, I met with a substance marked *gummi rubrum astringens*, and which I was told formerly fetched a very high price.

It is probably the *gummi adstringens gambiense* of Fothergill, and which Murray calls kino. I sent specimens of it to Professor Guibourt, who has described it as *Gomme astringente de Gambie*. It consists of small elongated tears, having an astringent taste,—externally blackish, with fragments of bark adhering: if small pieces be examined by transmitted light, they are observed to be ruby red. It is partially soluble in water, and appears to be a mixture of a gummy with a red astringent juice. It is probably the produce of *Pterocarpus erinaceus*.

SUB-ORDER: SWARTZIEÆ.

None of the plants of this sub-order yield any pharmacological agents; and their medicinal properties are but little known.

SUB-ORDER: CÆSALPINIÆ.

This is an important tribe, and contains several plants deserving of notice. To it belongs

Ceratonia Siliqua.

This is the Carob tree, or *St John's Bread*, a native of the south of Europe and of Asia. Its leaves are abruptly pinnate, its leaflets oval and obtuse. The flowers are racemose and small; the fruit is an indehiscent legume, four or five inches long, an inch broad, of a brownish-grey colour, and containing several seeds.

FIG. 167.—*Ceratonia Siliqua*.

It belongs to class *Polygamia*, order *Triecia*, in the Linnean arrangement. The pods contain extractive, gum, sugar, tannic and gallic acids: they have been used as fodder for horses. The tree received its name, *St. John's bread*, from a supposition that the so called wild honey on which *St. John the Baptist* fed, was the pulp of these pods. Moreover, it has been suggested that the shells of the pods might be the husks which the prodigal son desired to partake of with the swine.

ON THE
POWERS ON WHICH THE FUNC-
TIONS OF LIFE IN THE MORE
PERFECT ANIMALS DEPEND,

AND ON THE
MANNER IN WHICH THEY ARE ASSOCIATED
IN THE PRODUCTION OF THEIR MORE
COMPLICATED RESULTS.

By A. P. W. PHILIP, M.D. F.R.S. L. & E.
&c.

[From the Philosophical Transactions, with
large additions*, communicated to the MEDICAL
GAZETTE by the Author.]

[Concluded from page 933.]

*Of the manner in which the Powers of Life are
associated in the production of their more
complicated results.*

IN order to ascertain the seat of the power on which muscular contractility depends, it was necessary, in an early part of this paper, to enter on the relation which subsists between the muscular and nervous systems; and it appears from what is there said, that the nervous influence, whether in its effects on the muscles of voluntary or involuntary motion, stands only in the relation of a stimulus or directly debilitating power to the muscular fibre, according to the manner in which its organs are impressed; a result, I may observe in passing, peculiarly in accordance with all the other facts which have been stated respecting the nature of that influence, because the same observation, we shall find, applies to all the agents of inanimate nature which are capable of influencing the muscular fibre. For a similar reason it was necessary to point out the independence of the nervous on the sensorial power.

The relation which next demands our attention is that which subsists between the organs of the nervous influence and the living blood.

The first thing which here strikes us, is, that the blood-vessels and nerves uniformly accompany each other; from which we are led to infer that they co-operate in functions of very general necessity.

The powers of the nervous system, properly so called, we have seen, are all of a chemical nature. Of this nature, therefore, must be all processes in which they immediately co-operate. It is evident, that where such powers are employed, to render them efficient, materials must be provided on which they may operate; and

there must also, of course, be means by which these materials are duly exposed to their action.

The materials we find in the blood; the means, employed for the purpose of duly exposing them to the action of the nervous influence, in the capillary vessels, on which the minute extremities of the nerves (which we know, from numberless observations, are those parts of the nervous system by which its powers are immediately applied in the functions of secretion and assimilation, as well as the maintenance of animal temperature, and the excitement of the muscular fibre,) are distributed. As we find from experiments above referred to, that the central are the only parts of the nervous system properly so called, employed in the formation of the nervous influence, it appears from numberless observations that the extremities of the nerves are the only immediate organs of its powers in all its functions.

The motion of the fluids in the capillary vessels, as appears from many experiments related in the Philosophical Transactions for 1815 and 1831, and my Inquiry into the Laws of the Vital Functions, depends on a power which resides in themselves, in no degree depending on the power of the heart or arteries, except as far as is necessary for the due supply of blood to the latter, which form the reservoirs, from which the capillary vessels draw their supply. When, in the newly dead animal, a ligature is thrown round all the vessels attached to the heart, and this organ is removed, the motion of the blood in the capillaries continues unimpaired, and only fails in proportion as the supply from the large arteries fails*; the cause of the emptiness of the latter some time after what we call death.

By such means the materials on which the nervous influence operates are supplied and presented to it; and the means of supply, namely, the power of the heart and arteries, as well as that of the capillary vessels themselves, being, as we have seen, under the immediate influence of the same power which effects the chemical changes†, the supply is proportioned to the demand under the various conditions of the ever-changing functions; and under the same influence are the means of removal, whether of secreted fluids or solid parts become unfit for the purposes of life. Such are the circumstances above referred to, which

* See a paper On the Powers of Circulation, in the Philosophical Transactions for 1831, republished in my Inquiry into the Nature of Sleep and Death. See also my Inquiry into the Laws of the Vital Functions, Part II.

† See experiments detailed in the Philosophical Transactions for 1815 and 1822, and my Inquiry into the Laws of the Vital Functions, Part II.

* The additions were also intended for the Philosophical Transactions, but were too late for insertion in the new volume.

render it necessary that the muscles, whether directly or indirectly, employed in these functions should be subjected to the same power on which depend the functions of secretion and assimilation, namely, all muscles of involuntary propulsion, that is, with a very few exceptions, all muscles of involuntary motion.

It appears from some lately ascertained facts* that the secreted fluids are formed from the blood while still in its vessels, and not in the act of their separation by the secreting organs. That such must necessarily be the case appears from what has been said. The act of separation must be posterior to the changes effected by the chemical powers of the nervous influence. It is only while the blood is still in its vessels that it can in its entire state, or only mechanically divided by the diminishing size of the vessels, (a division which, taking place in every secreting organ, we must regard as necessary to its function,) be exposed to their operation; and we have reason to believe that it is only as the due changes have been effected, that is, only as the secreted fluid has acquired its due properties, that it applies the due stimulus to the particular vessels by which it is discharged: on the same principle that the due action of the intestines, by which they discharge their contents, is not excited if these contents have not acquired their due properties by the chemical processes which take place in the stomach and duodenum. Thus we have reason to believe that all secretions are formed in the circulating fluids, and are separated by the different secreting organs, in consequence of the action of the secreting vessels of each of these organs being excited only by the fluid which it is their function to convey.

Such are the nature and functions of the nervous power, and its relations to the muscular power and the powers of the living blood.

When we turn to the sensitive system we find ourselves in a new world. Here voltaic electricity, which we so successfully substitute for the nervous influence, can do nothing. The immediate organs of the sensorial power, we have seen, are as it were hedged in and defended from contact with any of the agents of inanimate nature.

On the one hand, we find the nerves of sensation, which so far partake of the nature of the external world that they are capable of receiving and propagating impressions from its agents, but in all other

respects are allied to the organs with which they are associated. By their vital powers they influence the immediate organs of the sensorium, and the functions thence resulting are the effects of one vital organ influencing another, and that by its vital properties alone; for it is evident that the properties operating here have nothing in common with those of any of the principles of inanimate nature. In the results consequently, we have seen all analogy with the phenomena of these principles, for the first time, lost; and necessarily so, none of the properties of the external world being immediately employed in their production.

The nerves of sensation, it appears from what has been said, convey not the nervous influence properly so called. The influence they convey is of a nature essentially different from that by which the muscles are excited, and the functions of secretion and assimilation maintained. They sufficiently partake of the nature of the sensorial organs to be capable of directly impressing them, and thus the latter receive all their impressions whether originating from without or within our own bodies.

On the other hand,—that is, that the sensorial organs may, without contact with any of the agents of the external world, impress those agents,—a more complicated machinery is required. The various nerves of sensation are the only means required for conveying impressions to these organs; but so simple an apparatus is not sufficient to convey to, and impress on, the materials of the external world, the dictates of volition. The powers of the nervous system are here called into operation by the sensorial powers, to which they are subjected; for it appears from many experiments, detailed in the *Philosophical Transactions* for 1815, and in my *Inquiry into the Laws of the Vital Functions*, that as the muscular is independent of the nervous power, but subjected to its influence, the nervous is independent of the sensorial power, but, in like manner, subjected to the influence of this power. In the case before us the nervous, influenced by the powers of the sensorial organs, supply a certain set of nerves with the stimulus which excites the muscles of voluntary motion, the immediate agents by which the materials of the external world are impressed.

I have had occasion to refer to the great variety of the phenomena of life, as one cause of their apparent obscurity. Such is their variety that we are at first view lost in attempting any arrangement or even enumeration of them. An essential step towards their arrangement, as appears from what has been said, is their division into those which are the immediate results

* See a paper by MM. Prevost and Dumas, *Ann. Chim. et Phys.* tom. xxiii. p. 90, et seq.; and Mr. Phillips's paper on the Secretion and Uses of the Bile, read at the Royal Society, Dec. 20, 1832, of which an abstract is given in the *Proceedings of the Royal Society*, vol. iii. p. 160.

of the cooperation of, the principle of life with the principles of inanimate nature, and those which have no immediate dependence on the latter powers; for all our functions mediately or immediately depend on the operations of the agents of inanimate nature. All are more or less directly excited by impressions originating in their agency.

The most purely sensorial functions, our pleasures and pains, are as dependent, though more remotely, on the excitement maintained by them, as the functions of the organs immediately impressed by them. Have not the excitements of memory, for example, as much originated in their impressions, as their more direct effects on the part impressed? And when the nature of our bodies and the circumstances in which we are placed are duly considered, what other result could be expected? Our organs, being composed of the same materials as the world which surrounds us, can only be directly influenced by agents of their own nature; and from that world, and by the medium of those organs, all the materials, not only of our acquired knowledge*, but of our enjoyments and our sufferings, are derived.

And as on the one hand, all our functions are more or less immediately excited by impressions made by the agents of the external world on organs composed of materials of their own nature, on the other, we have no power of influencing them, but through similar means. The only means of exciting our mental functions are the impressions of those agents on the organs of sense, and our only means of operating beyond our own bodies are through our organs of motion. Even when by our mental powers we influence those of other sentient beings, it is as much, though not so directly, by impressing the agents of the external world by the latter organs, as when we raise a weight or throw a stone.

SUCH is the general outline of the vital and sensitive systems; and the manner in which the various powers of the living animal are related in the formation of these systems. By the foregoing means, the nervous power maintains the vital functions properly so called; and the sensorial power is brought to cooperate with the powers of inanimate nature, powers which have no properties in common.

The functions by which these objects are effected include the more complicated functions which belong to the individual

systems. But the most complicated remain to be considered—those functions in which both systems so co-operate that they can hardly be said to belong to either. Before entering on them, however, it will be necessary to make some observations on the differences of the laws which regulate the two systems, and consequently essentially modify all the functions in which they co-operate.

It appears from the facts adduced in my paper on the Nature of Death, published in the Philosophical Transactions for 1834, that the vital and sensitive systems obey very different laws, the difference depending on the vast difference in the nature of the sensorial and nervous powers, the leading powers which pervade all their departments, and to which all their other powers are subservient.

These other powers, it appears from what has been said, are the same in both, namely, the muscular power and the powers of the living blood, and, in the sensitive system, the nervous power itself; for in this system all the other powers of the living animal are directly subjected to the sensorial power, while none of the powers of the vital system have any direct influence on it, their influence on the sensorial power being through the medium of its organs, the structure and well-being of which immediately depend on the vital powers.

In other respects also the laws of the two systems essentially differ. Nor will these differences surprise us, when it is recollected, as appears from the facts which have been stated, that while the leading power in the vital system is one of those powers which operate in the external world, that of the sensitive system not only possesses no properties in common with the agents of inanimate nature, but depends on a set of organs unapproachable in their healthy functions by any such agents.

When the facts adduced in the paper just referred to, and that on the Nature of Sleep published in the Philosophical Transactions for 1833, are duly considered, it will appear that a principal cause of difference in the laws of these systems depends on the difference of the laws of excitability in the organs of their leading powers. In those of the leading power of the sensitive system, all degrees of excitement are followed by a rapid proportional exhaustion of excitability; so that the effect of the usual stimulants of life for a few hours, renders a state of inactivity essential to the maintenance of their health: while the exhaustion of the excitability of the organs of the leading power in the vital system by those stimulants, is the operation of many times as

* We are born with the knowledge which is immediately essential to our existence. The infant knows as well how to suck and how to breathe as the adult, and these are as much acts of volition as those which are the results of experience. See my paper on the Nature of Death.

many years, the one determining the recurrence of sleep, the other the natural duration of life.

The properties of the muscular fibre, and the relations it bears to the other organs*, admirably adapt it to cooperate with the leading powers of both systems. This fibre, it appears from many of the phenomena of life, experiences no sensible exhaustion from moderate excitement*. In health its excitement in the vital system is always such; and it is evident from what is said in the papers just referred to, that, were not this the case, the continuance of life would necessarily be of very short duration. We know from the phenomena of disease that even in slight degrees of exhaustion of the muscular fibre employed in the vital system, its due excitability is restored with difficulty; and that no great degree is necessary to prove fatal. That its due excitability may be restored, it must still retain such a degree of it as is necessary to the continuance of the vital functions, however feebly performed. Under such circumstances, if the operation of the offending cause be removed, the organs of those functions gradually though slowly, in proportion to the degree of exhaustion which has taken place in the muscular fibre employed in the vital functions, and the organs of the nervous power properly so called, regain their due excitability.

The moderate effect and uniformity of the stimuli which, in health, excite the muscular fibre in the vital system, secure it against sensible exhaustion. It is otherwise in the sensitive system, because there this fibre is often exposed, in the ordinary functions of life, to a stimulus exceeding in its effects the limits of moderate excitement; but the exhaustion consequent on this excitement is here attended with little inconvenience, because the organs of the only stimulus which excites it in this system suffering a corresponding exhaustion, its stimulus is withdrawn; and thus it is allowed to recover its excitability, its continued action here not being essential to the continuance of life, and means being provided in the healthy functions of the system for the restoration both of its excitability, and that of the organs which supply the stimulus which excites it.

In those, in whom, from habits of dissipation, extreme labour, or other causes, the excitability of the vital system is to a certain degree exhausted, but who, as they approach middle life, cease to be exposed to such causes, and during that portion of life, that is from thirty to fifty or fifty-five, feel little incon-

venience from the effects of their early habits, there still being in the vital system sufficient excitability for the usual functions of life; after this period, when the defect of excitability begins to be felt sooner or later by all, feel the effects of its expenditure which had been so profuse in early life: many striking instances of which I have witnessed. Similar observations apply to long protracted illness, severe misfortunes, or any other cause which at any period of life in a great degree, and for a considerable length of time, tend to exhaust the excitability of the vital system, although for a certain time the individual may enjoy his usual health after such causes have ceased to operate*.

The organs of the leading power in the vital system, as appears from the facts stated in my paper on the Nature of Death, possess at birth a high degree of excitability, a degree beyond that proportion which constitutes the firmest state of health—the cause, as there pointed out, on which the growth of the body appears to depend, and the source of many of the most fatal diseases of infancy—which is by the operation of the usual stimulants of life gradually reduced till it bears a due proportion to those stimulants, by which the powers of the constitution are confirmed. At length from their continued operation the fault is a defect, not a redundancy, of excitability, to which every day necessarily adds, till they can no longer excite the organs on which that power depends; for in every instance the immediate cause of absolute death, which is very different from what we call death, is the failure of that power†. And here as there are no means in the constitution, as in the case of the organs of the leading power in the sensitive system, of restoring the excitability of its organs, they at length finally cease to be excited. Thus it is that in almost all cases of great longevity we find that there has been little exposure during life to powerful causes of exhaustion of either body or mind, for we have seen that the nervous is immediately under the influence of the sensorial power; and that such instances are most frequent in the colder of the temperate climates; heat, on the one hand, tending to exhaust excitability, and extreme cold, on the other, to render us less capable of excitement.

In considering the laws of excitability it is necessary to bear in mind an essential property of all those agents which are capable of calling it into action, and

* My papers on the Nature of Sleep and Death.

• See what is said of the excitability of the two systems in my papers on the Nature of Sleep and Death.

† My paper on the Nature of Death. Philosophical Transactions for 1834.

which has obtained less attention than its great importance in the treatment of disease demands. There is no agent capable of influencing either of the two systems into which the functions of the living animal arrange themselves, whether it be such as makes its chief impression on the mind or body, which is not capable of acting either as a stimulating or directly debilitating power according to the degree in which it is applied. There is none which may not be applied in so small a degree as to act as a stimulant, and in so great a degree as to act as a directly debilitating power. The most depressing passion in a comparatively small degree will excite, the most exciting in an excessive degree directly debilitate; and the same stimulus by which either the nervous or muscular fibre is directly excited, will by its excessive application directly deprive it of power. I know of no exception to this law. All medicines within a certain range, excite, and unless the excitement exceeds the degree which produces no correspondent depression, (for such a degree of excitement, we have seen, is compatible with the laws of the vital though not with those of the sensitive system*,) it acts as a permanent tonic. All, beyond their stimulant range, act as directly, and although within that range, if of a certain intensity, as indirectly debilitating powers with respect to both systems†.

Thus it is that tonics never produce much immediate excitement. They have little of the effect of mere stimulants. Their peculiarity is in the permanence, not the power, of their stimulant effect; and on this both their good and bad effects depend; and thus also it is, that a medicine, debilitating in the usual dose, in a lessened dose acts as a tonic. This I have found to be, in a striking degree, the case in the instance of mercury‡, by which means we are enabled permanently to re-

lieve a class of diseases which have hitherto resisted all our means. I have been at much pains to ascertain the largest dose of mercury which acts as a permanent tonic; that is, provided it is not allowed to produce salivation, which, for evident reasons, however produced, is itself debilitating, and which the following doses are as capable of as larger ones, and under certain circumstances more so*; but from their use it never suddenly supervenes; there is always, under whatever circumstances, sufficient warning to prevent it by discontinuing the minute doses for one or two days; nor, indeed, do any of the other bad effects of a course of mercury attend their use. They neither open the skin as a course of mercury does, nor does the sudden closing of the skin, under their use, from cold or any other cause, ever do harm, the quantity of mercury at any one time in the habit never being such as to cause inconvenience to whatever part directed. The doses here referred to, I found, in most constitutions, to be the twentieth part of a grain of calomel, or half a grain of blue pill, according as best suits the constitution, repeated three times in twenty-four hours. These doses possess about the same power, the former perhaps being rather the more powerful. Many circumstances detailed in my treatise on these doses must be attended to in order to secure their good effects.

We have hitherto been employing mercury in its debilitating doses only; that is, doses which either produce a directly debilitating effect, or such excitement as, in the vital system, is followed by a corresponding depression; and hence has arisen the prepossession against it, which, however, such are its healing powers, has not prevented its being more generally employed in this country than any other medicine; in which the best informed countries of Europe are gradually following our steps.

It is evident from many facts, stated in my papers on the Nature of Sleep and Death, that each of the foregoing systems is a whole, which cannot be influenced in any one part without a tendency to be affected in all others; a property which perhaps more than any other influences the progress of their deviations from the healthy state; for every part more or less feeling the change effected in any one, if there be any from accidental causes more liable to disease than the rest, this part particularly feels the cause which operates on all; and, as I shall soon have occasion to point out more particularly, is even the means of diverting its effects from every

* My paper on the Nature of Sleep in the Philosophical Transactions for 1833.

† See what is said on this subject in my treatise On the Influence of Minute Doses of Mercury in restoring the Functions of Health, and my Gulstonian Lectures on the more obscure affections of the Brain, also in the recapitulation at the end of this paper. All my treatises, to which I have occasion to refer, are more or less founded on the principles here recapitulated; and consequently in them more or less copious references to the facts on which these principles rest, became necessary. In order to arrive at the conclusions of the present paper, it was necessary to state the whole of those facts with their various bearings, which I have done in as concise a manner as the requisite perspicuity appeared to admit of. In the less familiar parts of the subject, it requires some care to avoid being misunderstood.

‡ See my Treatise on the Effects of minute doses of Mercury in restoring the Functions of Health.

other part. Thus it is that diseases of continuance often become complicated, and that an affection, attended with little risk in the part first impressed by the offending cause, may become formidable by its secondary effects.

The power which operates here has been termed the sympathy of parts, the effects of which I have considered at length in a treatise on the more obscure diseases of the brain, being the Gulstonian Lectures delivered at the College of Physicians in 1835. I am now, after referring to its more prominent effects, to consider the nature of this function, and the powers on which it immediately depends; which will lead us to the last part of the subject of this paper,—the means by which the most complicated functions are effected.

As it appears from the experiments above referred to that the organs of the sensorial and nervous powers, the leading principles of the two great systems, the functions of which comprehend all the functions of life, although both belonging to the brain and spinal marrow, are distinct sets of organs; the one set being confined to a comparatively small portion of these organs, the other distributed through the whole of them, from the uppermost surfaces of the brain and cerebellum to the lowest portion of the spinal marrow; and as numberless observations evince that the immediate cause of sympathy exists in the central organs alone*, it follows that these systems must have different centres of sympathy, that if the different parts of each system sympathize, it cannot be through the same centre.† Now it appears from the phenomena of disease, compared with the results of the experiments just referred to, that each of the centres of these systems is often influenced with so little disturbance to the other, that disease of either system, especially when of a chronic nature, often spreads to distant parts of the system in question, without much affecting the other; a favourable result in the sensitive system, because it is only in proportion as the organs of the vital system are implicated that life is endangered; but in the vital system the most fruitful of all causes of obscurity, and that in diseases of the most formidable nature, to which many have fallen, and still fall a sacrifice; for so ill supplied are some of the vital organs with nerves of sensation, that in them diseases of sympathy often make a fatal progress without the state of the part originally affected having attracted attention, and without its restoration, that of the part

secondarily, but more prominently, affected is impossible*. Thus also it is,—that is, in consequence of the one system often suffering with little disturbance to the other,—that extreme suffering not unfrequently continues for years without materially impairing the functions of life, the organs of suffering belonging to the sensitive system; while in other instances immediate danger presents itself with so little previous suffering, that even the medical attendant is unprepared for it.

The latter evil can only be obviated by a careful study of the laws of sympathy in the vital system, and particularly by ascertaining what organs are most inclined to be affected by what others; for although the function of sympathy is, like other functions, influenced by causes peculiar to the individual, it is in a great degree regulated by principles which more or less prevail in all†.

From the facts just referred to we easily perceive the cause of the sympathy by which every part of each of the foregoing systems is capable of influencing every other. Each is regulated by a leading principle, and in consequence of this, under an influence by which the affection of any one part tends to affect all others; because as all parts of each system both influence this principle, and are influenced by it, it necessarily follows that all must, through it,—that is, through the central organs of each system, which alone are the immediate organs of its leading principle,—feel the affections of each. Such, together with the laws I am now to consider, is the source of the function to which the term sympathy has been applied, a principle, as I have just had occasion to observe, which perhaps more extensively than any other regulates the course of disease.

As each of the preceding systems is formed into a whole by its leading principle, the relation which these systems bear to each other have a similar effect with respect to the whole frame; for the affection of any one of its parts tends more or less, though much less powerfully than in the individual systems, to influence all

* The internal water in the head of children, for example, has till within the last thirty years, been almost uniformly fatal, having been treated as an original affection of the brain. Dissection having now proved it to be a secondary affection depending on the state of the liver, there are few serious diseases in which the treatment is more uniformly successful, if it has not been allowed to arrive at its last stage. The original affection, which does not betray itself by any prominent symptom, being removed, its consequences yield to the means, which are powerless while it continues to operate. Other affections of the head, certain forms of pulmonary consumption, and many other diseases, might be adduced as illustrating the same principles. Ibid.

others. The means by which the relation between the sensitive and vital systems, and consequently the most complicated functions, are maintained, we are here to consider; to some of them I have already had occasion to refer.

WE have seen that the nervous power properly so called, the leading power in the vital system, is immediately under the influence of the sensorial power, the leading power in the sensitive system, and constitutes the medium through which all that part of our intercourse with the external world, by which the latter power influences it, is maintained. This therefore is the first bond of connexion to which I shall refer between the sensitive and vital systems. The second is the means by which the organs of both systems are maintained; for, as I have already had occasion to observe, the sensitive has a dependence on the vital system, for the maintenance of its organs, as the latter, we shall find, has a more remote dependence on the former, for the maintenance of its organs; the connexion thus established between them being increased by both systems equally depending for the maintenance of their organs on the muscular power and the powers of the living blood; both of which are in their turn subjected to the nervous, and the former certainly, and the latter, we have reason to believe, through the nervous, also to the sensorial power.

The sympathy which prevails through all parts of each system also contributes to the influence of these systems themselves on each other; because the state of the parts secondarily affected in consequence of the power of sympathy, more or less influences both systems, all parts being more or less supplied with nerves from both.

But we have sufficient evidence in the symptoms of disease, compared with the results of the experiments referred to, that in the phenomena of sympathy, as in the instances just pointed out, the central organs of the sensitive directly influence those of the vital system. A sympathetic pain it is well known referred to any part will at length produce actual inflammation of the part. Now while the pain alone exists, we know that the derangement which produces it is in the central organs alone of the sensitive system, and in no degree in the part to which it is referred; and we also know from the facts which have been stated, that there is no channel through which this derangement can influence either the vital nerves or the vessels of the part, but through the central organs of the vital system.

When the affection of the nerves or

vessels of the part is the original disease, it influences the central organs of both systems by the actual disease of the part, every part being supplied with nerves belonging to both systems; but in the former case there is no other channel of communication than that just referred to. The central organs of the sensitive, having no direct power over either the vital nerves or the vessels, can only influence them through the central organs of the vital system. Thus arises a double bond of connexion between the two systems, the central organs of the sensitive system directly influencing those of the vital system, and the nerves of the sensitive system being necessarily influenced by all deviations from a state of health in whatever part, for all parts may be affected through the central organs of the vital system, the degree to which the effect in the sensitive system takes place being proportioned to that in which the part is supplied with nerves of sensation. As the central organs of the sensitive, directly influence those of the vital system; the latter, through the extremities of the different nerves with which the two sets of organs are associated, influence the former. Hence we have just seen the fatal obscurity of many diseases of those vital organs, which are ill supplied with nerves of sensation; and as the more chronic the disease, the less it disturbs the sensitive nerves, it is in the more chronic cases that the obscurity is greatest, and consequently attended with the greatest risk.

Different parts of the central organs of the sensitive system correspond to different parts of the general frame. This is perhaps sufficiently proved by our being enabled by experience to refer our sensations to the seat of the cause which excites them; but in many of the inferior animals, where both the brain and spinal marrow partake of the organs of the sensorial power, it may be proved by direct experiment, because after the removal of the brain we find the sensorial power lost only in those parts which derive their nerves from that organ.

But how comes it that the central organs of the vital system also have a peculiar relation to certain parts of the general frame, the nerves associated with these organs conveying, as appears from what has been said, their combined influence, which is bestowed alike on all vital organs?

It is a law of the animal economy, amply illustrated by the phenomena of disease, that when an impression influencing the system generally is, by previous debility or any other cause, directed to a particular part, its operation is diverted from all others. Now it appears from a thousand

phenomena that the suffering of the sensitive system, referred to any particular part, is sufficient, under certain circumstances, in consequence of the influence of the central organs of the sensitive, over those of the vital system, and, through the latter system, over all parts of our frame, to direct to that part the effects of derangement excited in this system. Thus even a diseased organ will often regain its healthy state, when the disease has spread to another, particularly if in the latter, it takes deeper root, if I may use the expression. It is a daily occurrence for a disease of function to be finally removed by a disease of structure being established in another organ. Hence the good effects of artificially exciting disease in external parts to relieve those more immediately essential to life; and the still more salutary effect, when the laws of our frame themselves produce the same effect, because here it is the uninfluenced result of those laws, whereas in the former case their tendency is constrained by artificial means. Thus for example it is that the inflammation of a gouty joint or other external disease often relieves the derangement of a vital organ, and that artificially repelling this effort of the constitution to save a vital part, has so often proved fatal.

On the facts that the central organs of the vital system directly influence the functions both of the vital nerves and of the vessels of every part, while those of the sensitive system have no direct influence on either, many of the phenomena of disease depend; because it is only in proportion as these nerves and the vessels of the part are influenced, that any disease of the part itself exists, and consequently that there is any tendency to derangement either of function or structure in the part; of function alone if the nerves alone are affected, of structure also as soon as the vessels partake of the disease. Hence it is that the tendency to change of structure, except where it takes place by imperceptible degrees, is, *ceteris paribus*, always proportioned to an inflammatory tendency which may be detected in the part, this tendency being the first indication that the vessels partake of the disease; and hence the importance of carefully watching and checking its approach, if the part be one essential to life, in all cases of deranged function of, or even of painful sensations referred to, particular parts; for the long continuance of either may through the foregoing channels excite the most formidable diseases in vital parts, which will generally be obstinate in proportion to the length of time the previous symptoms have lasted. The longer continued the habit of disease of whatever nature and

whatever part, the more obstinately the parts concerned retain the morbid action.

EXTENSIVE as the foregoing relations of the vital and sensitive systems are, they are not the only ones. To determine the whole of them it is necessary to review the functions of the more perfect animals, and in particular correctly to ascertain the line of distinction between those of the two systems; in order to ascertain whether there be any beside those just pointed out in which they cooperate, and which consequently contribute to their dependence on each other.

I made many experiments with a view to draw the line of distinction between the vital and sensitive functions; and that the result might be the more certain, the attempt was made by two sets of experiments, conducted on different principles. By the one it was attempted to ascertain what functions remain when the sensorial power is withdrawn; by the other, what functions fail with the failure of the nervous powers; and the correspondence of the results of these sets of experiments tends to confirm the inferences from both*.

Much confusion had arisen from physiologists having neglected to ascertain this line. M. le Gallois, one of the most acute, soon found his difficulties from this cause such, that he was obliged to confess himself unable to proceed, and leave to his successors the task of removing them. He had adduced sufficient proof of the spinal marrow, to which the nerves of respiration belong, being capable of its functions independently of the brain; yet on the removal of a part of the brain, the medulla oblongata, respiration ceases. This difficulty he acknowledges he sees no means of removing, calling it "*un des grands mystères de la puissance nerveuse, mystère qui sera dévoilé tôt ou tard, et dont la découverte jettera la plus vive lumière sur le mécanisme des fonctions de cette merveilleuse puissance.*"

If the preceding facts be kept in view, it is evident without much consideration that none of the functions of the sensitive have any other dependence on the powers of the vital system, but for the due structure and wellbeing of their organs. The nature of the functions of the vital system here requires more consideration. They include respiration; circulation; those processes by which the secreted fluids are formed; those, namely the more immediately assimilating processes, by which our food is converted into the various organs of our bodies, and such parts of them as have become unfit for the pur-

* Inquiry into the Laws of the Vital Functions, Part II.

poses of life are separated and expelled, for all are in a state of change; and those by which the due temperature is maintained.

Does the sensitive cooperate with the vital system in any of these functions?

From the line of distinction, determined by the experiments just referred to, it appears that in one of them only is there such a cooperation.

I have in the last of my papers published in the *Philosophical Transactions* for 1829 considered at length the nature of respiration, and have, as far as I am capable of judging, adduced such facts as prove that the muscles employed in this function are, in the full sense of the word, muscles of voluntary motion. The first act in respiration is the impression made on the sensorium, the sensation excited by the want of fresh air in the lungs. We are enabled to supply it and remove the uneasiness, by exciting, through the nervous system properly so called, certain muscles subject to the will.

Respiration thus depending on the combined operation of both systems, is as effectually destroyed by a failure of the sensation which makes us will to inspire, as by that of the nervous or muscular power by which the will effects its object. Thus the difficulty of M. le Gallois disappears. It is true that the spinal marrow and its nerves are capable of their functions independently of the brain, and that the nerves which excite the muscles employed in respiration are supplied by the spinal marrow, but in this function it is an act of volition which excites them. They are quiescent till this act takes place. Hence it is that respiration ceases on the removal of the medulla oblongata, because by the removal of this part of the brain the power of sensation in all parts below the head and consequently of volition, as far as relates to those parts, is destroyed. Hence also the fact, above referred to, that the vital has a remote dependence on the sensitive system, independently of the means of obtaining nourishment, for the maintenance of its organs. If the muscles of respiration were not in the strictest sense muscles of voluntary motion, our powers of volition would in an essential respect be imperfect; for the due regulation of their action is essential in the formation of articulate sounds, the chief means by which our sensorial powers are enabled to influence those of other sentient beings. In many of the less perfect animals, respiration like circulation is performed by powers of involuntary motion, as in the still more imperfect, sustenance is obtained by the same means, the functions of the lowest class of animals thus in their nature approaching to those of the vegetable. In

proportion as the animal ascends in the scale of being, the vital have a greater dependence on the sensitive powers; that is, in proportion as the latter powers improve, the former become more dependent upon them.

In the papers on the *Nature of Sleep and Death*, published in the *Philosophical Transactions* for 1833 and 1834, I have pointed out how much the functions of the more perfect animal are influenced by this peculiarity of respiration, the only vital function, properly so called, in which the sensorial power cooperates; a circumstance which more generally perhaps than any other, which is equally of a local nature, influences the phenomena both of health and disease. In this function therefore we find a powerful bond of connexion between the sensitive and vital systems, and one, as appears from the papers just referred to, of the most extensive operation.

SUCH are the means by which the frame of the more perfect animal is formed into a whole, and the function of sympathy and its other more complicated functions above enumerated effected. A powerful connexion is established among all parts of each of the systems into which the functions arrange themselves, depending on each being regulated by a leading power which influences every part of the system to which it belongs, and in its turn is influenced by every part of it: and these systems themselves are intimately related in consequence of the nervous, the leading power in the vital system, by means of the control which the organs of the sensorial power exercise over it, being employed in the accomplishment of many of the sensitive functions; and the sensorial power, the leading power in the sensitive system, being employed in one of the most important of the vital functions; by both symptoms not only depending for the maintenance of their organs on the same powers, but more or less directly on each other; by the powers common to both systems being under the influence of the leading principles of both; and by all affections of whatever part, whether original or sympathetic, necessarily influencing both its sensitive and vital nerves, and consequently the central organs of the systems to which they belong.

FROM the whole of the facts referred to in the preceding paper, the great outline of the laws which regulate the functions of the more perfect animal is derived. The parts of which it consists, from the complicated nature of the subject, being very numerous, it is necessary, in order to place it in a clear point of view, concisely

to recapitulate them; and as in the preceding paper, I commenced with the more simple, and was, by their intimate connexion with the more complicated powers, led to them; I shall in the recapitulation, that they may be viewed in both directions, begin with the more complicated, which by the same means will lead us to the more simple powers.

BESIDE the mechanical powers, of which the living animal evidently partakes in common with inanimate nature, it possesses, we have seen, four distinct powers, apparently peculiar to itself, having no direct dependence on each other, but each depending on the other three, for the maintenance of its organs; the sensorial, the nervous, and the muscular powers, and the powers of the living blood.

By these powers are maintained the two systems into which the various functions arrange themselves, the vital and sensitive systems, the object of the one being the maintenance of our bodies, of the other, our intercourse with the external world.

THE organs of the sensorial power in man have their seat in the brain. They can be excited by no other means than the influence conveyed by the nerves of sensation, in the most extended sense of the expression, in every instance called into operation by impressions made on their extremities by agents which belong to inanimate nature, either existing within our own bodies, or making their impression from without; and, on the other hand, there are no means by which the sensorial organs can influence those agents but through the intervention of the powers of the nervous system properly so called. The nature of the sensorial power, we have seen, admits of no direct intercourse between its organs and the agents of inanimate nature, because none of the properties by which it operates have any thing in common with those of such agents; and as these organs can only receive impressions from the external world through the nerves of sensation, with which they are associated, they can only impress the agents of that world through the muscles of voluntary motion, excited by the nerves associated with them. Thus it is necessary, as we have by direct experiment found to be the case, that the organs of the nervous system should be placed under the control of the sensorial power. Through the same channel, we have seen, this power also, in some of their functions, controls the muscles of involuntary motion; and we have reason to believe, although the point has not been ascertained by direct experiment, all the powers of the living blood. And such, as

appears from facts above referred to, is its influence on the nervous, and through it, on the muscular power, and we have reason to believe on the powers of the living blood, that it can not only excite, but impair and instantly destroy all these powers, according to the nature and power of the causes which influence its organs.

The circumstance of the muscular, as appears from facts above referred to, being the moving power of the blood in the vessels as well as the heart, greatly extends the influence of those powers which control it, namely, the nervous power properly so called, and the sensorial power acting through it.

The only respects in which the sensorial power is related to the subject of this paper, are in the impressions it receives from the nerves of sensation, and the functions in which it co-operates with the nervous and muscular powers. Sensation and volition are the only sensorial powers employed in the maintenance of life.

While the organs of the sensorial power are thus capable of more or less directly influencing all the other organs of the living animal, they more or less feel in their turn, through the medium of the nerves of sensation, which, we have seen, convey an influence of wholly a different nature from that conveyed by the nerves associated with the organs of the nervous power properly so called, all changes effected in any part of our frame. By these means, this power constitutes the leading principle in the sensitive system, of which its organs form the central parts.

THE organs of the nervous power properly so called, have their seat equally in the brain and spinal marrow, and throughout all parts of them; and are excited, on the one hand, by the direct influence of the sensorial power, and on the other, by agents influencing the vital organs throughout every part of the frame; all of which, as in the case of the impressions made on the nerves of sensation, whether existing in our own bodies or making their impressions from without, are agents of inanimate nature.

The immediate functions of the unaided nervous power are the excitement of the muscles of voluntary motion in all their functions, of the muscles of involuntary motion in some of their functions; and the immediate functions of this power in co-operation with the muscular power and the powers of the living blood, all the powers of both of which are directly subjected to its influence, are the formation of the secreted fluids, the maintenance of animal temperature, and the various more

immediately assimilating functions, — namely, the functions by which, on the one hand, our food is converted into our various organs, and, on the other, those parts of them which have become useless, are separated and expelled,—which renders it necessary that the muscles of involuntary motion as far as they co-operate in these functions, which with few exceptions include the whole of these muscles, should, as we have seen from direct experiment is the case, be under the immediate influence of the nervous power.

Neither the brain nor spinal marrow in the functions of the vital system acts through the other of these organs, as the brain is found to do through the spinal marrow in many of those of the sensitive system; each directly influencing every part.

The direct influence of the nervous power, it appears from what has been said, extends to all the functions of the system, with the exception of those of the sensorial power, which it only influences through other functions. It directly influences, and is directly influenced by, all the vital functions properly so called, and hence constitutes the leading principle of the system to which they belong, therefore termed the vital system, of which its organs form the central parts.

THE circumstance of each of the foregoing systems being under the influence of a leading power, which is both capable of influencing and being influenced by every part of it, is the cause of that powerful sympathy which exists among all its parts, and which we have seen often essentially influences either system with but little disturbance to the other, on which many of the most important phenomena of disease depend.

THE muscular power, which has its seat, we have seen, in the muscular fibre itself, and the powers of the living blood, which have their seat in the blood itself, perform subordinate parts. They are equally employed in both systems for the maintenance of their organs. The latter supplies the materials endowed with the principle of life on which the nervous power operates in the formation of the secreted fluids, the maintenance of animal temperature and the various more immediate functions of assimilation; while the former, to which the vessels as well as the heart owe their power, supplies the means by which these materials are duly exposed to the operation of the nervous power, by which their necessary changes are effected; that is, to the influence of the extremities of the nerves, by which the nervous power operates in all these functions, as well as in the excitement of the muscles; for as

the brain and spinal marrow, as we have seen proved by direct experiment, are the only parts of the nervous system employed in preparing the nervous influence, the minute extremities of the nerves are the only immediate organs of its functions; as the extreme parts of the sanguiferous system, the capillary vessels, are the organs by means of which the blood is immediately exposed to its influence.

That the capillary vessels may be, as little as possible, influenced by adventitious causes in functions of such importance in the animal economy, we find on the one hand, as appears from experiments above referred to, that the motion of their blood depends wholly on their own powers, the larger arteries which depend for their supply of blood on the heart, being only the reservoirs from which they draw their supply; and that, on the other, they are not controlled by the nervous influence through the medium of the heart, but receive this influence directly from its source: and so correct are these positions, that even the removal of the heart, if effected without any considerable loss of blood, produces no immediate effect either on the action of the capillaries, or the control which the nervous power exercises over them.

SUCH are the individual powers of the living animal, their seat, the relation they bear to each other, and the manner in which their several functions are effected.

BUT the most complicated functions, it appears from what has been said, depend on the relations which subsist between the two systems themselves, into which the functions of all these powers are arranged.

They are related to each other, we have seen, by the nervous, the leading power in the vital system, in consequence of the control exercised over it by the sensorial, the leading power in the sensitive system, being employed in many of the functions of the latter; by the sensorial being employed in one of the most important of the vital functions, this peculiarity of respiration, for in no other of those functions is there any such co-operation, extensively influencing the phenomena both of health and disease; by both systems depending for the maintenance of their organs on the same powers, and more or less directly on each other; by the powers common to both systems, the muscular power and the powers of the living blood, being under the influence of the leading powers of both; and by all affections of whatever part necessarily influencing both its sensitive and vital nerves, and consequently the leading powers of both systems.

As the various parts of each system are

formed into a whole by all parts of each influencing and being influenced by its leading principle, so all parts of the animal body are formed into a whole, no part of which can be affected without tending more or less to affect all others, by the means just enumerated, by which these systems influence each other. Such are the foundations on which the laws of sympathy depend, a principle which, as I have endeavoured in a cursory way to point out, more than any other, influences the course of all deviations from a state of health.

THE functions of all the powers of the living animal, we have seen, are mediately or immediately excited by organs belonging to inanimate nature. Our organs are composed of the same materials with the external world, and can only be immediately impressed by agents of their own nature. It is true that the sensorial functions are the results of one vital part acting on another, the sensitive nerves on the immediate organs of the sensorial power; but the impression these nerves convey is in every instance received from the agents of inanimate nature. Here both the agent and the organs impressed are of the same general nature, being composed of similar materials with our other organs. The peculiarity of the results depends on vital properties alone being employed in their production, whereas in all other functions of the living animal, the vital properties of the organ co-operate with the properties of the inanimate materials of which it is composed. Hence it is that its functions admit of being immediately excited by the agents of inanimate nature, which, having no properties in common with the only properties employed in the sensorial functions, cannot directly co-operate in their production; and hence, we have seen, the analogy, which all the functions of the living animal, with the exception of the immediate functions of the sensorial organs, bear to the operations of inanimate nature, and the total loss of all such analogy in the latter.

Every agent capable of exciting any of the functions of the living animal, we have seen, acts as a stimulant or directly debilitating power, according to the degree in which it is applied. In the sensitive system their stimulant effect is always followed by a proportional exhaustion of excitability; in the vital system, only when the excitement exceeds a certain limit. I speak in the latter case of a sensible exhaustion, an exhaustion beyond that produced by the usual stimulants of life, which, in the vital system, is too gradual to be perceived, and as far as relates to any particular stimulant employed within

such limit, is so trifling that it may be safely overlooked. Hence it is that the vital system appears to possess an excitability which is not exhausted by stimulants except when applied in excess. It is essential, we have seen, in the treatment of disease, to keep in view these properties of all agents capable of influencing the functions of life, that we may, as much as the nature of the case admits of, keep within the stimulant range of our remedies; and within that range, as far as possible, avoid the degree of excitement which produces sensible exhaustion of the vital organs; under which circumstances medicine always operates as a permanent tonic, more or less powerful according to its peculiar properties.

WITH respect to the nature of the powers of the living animal which we have been considering, the sensorial and muscular powers, and the powers peculiar to living blood, we have found to belong to the living animal alone, all their peculiar properties being the properties of life. The functions of life may be divided into two classes, those which are effected by the properties of this principle alone, and those, by far the more numerous class, which result from the cooperation of these properties with those of the principles which operate in inanimate nature. The nervous power we have found to be a modification of one of the latter principles, because it can exist in other textures than those to which it belongs in the living animal, and we can substitute for it one of those principles without disturbing the functions of life.

Late discoveries have been gradually evincing how far more extensive than was supposed, even a few years ago, is the dominion of electricity. Magnetism, chemical affinity, and (I believe, from the facts stated in the foregoing paper, it will be impossible to avoid the conclusion) the nervous influence, the leading powers in the vital functions of the animal frame, properly so called, appear all of them to be modifications of this apparently universal agent; for I may add, we have already some glimpses of its still more extensive dominion*.

IN the preceding paper my objects have been to review the whole of the functions of the more perfect animal, to ascertain the nature of the powers on which they depend, the seat of each of these powers, the manner in which they are employed in effecting their several functions, and the manner in which they are associated in

* See Dr. Roget's Treatise on Electricity.

producing their more complicated results. Nothing in any part of the subject has been taken for granted, no position having been advanced without a reference to the observations or experiments on which it is founded.

I have here for the first time made an attempt, which could not be done till all the facts on the subject had been ascertained, to point out the manner in which the different powers of the living animal influence each other, and thus conduce to their more complicated results; by which, being enabled to analyse these results, it might easily, were this the proper place, be shown, that we better see the operation of its different powers in the various deviations from a state of health, and can, under certain circumstances, better regulate the means of obviating them.

STRYCHNOS NUX VOMICA IN DYSPEPSIA.

To the Editor of the Medical Gazette.

SIR,

IN a late communication to your journal, by Mr. Mellor, of Manchester, upon the curative effects of the strychnos nux vomica in certain diseases of the digestive organs, that gentleman observes, "that the late Dr. Belcombe, of York, was in the habit of using it for the relief of indigestion, but in what particular form of this complaint, I am not at present prepared to say." I beg to state that my late father prescribed the strychnos very generally, and with almost constant success, in those forms of stomach affection denominated pyrosis and gastrodynia, particularly when the disease appeared to proceed from some morbid irritability of the nerves of that organ; and that he was preparing a detailed account of his observations upon this medicine when he was attacked by a severe illness, from which he never recovered.

I promise myself some time the pleasure of laying this and other details of his successful practice before the medical profession.

Since the introduction of the alkaloid principle, which I am happy to see has obtained a place in the Pharmacopœia, I have been in the habit of employing it in doses of $\frac{1}{12}$ to $\frac{1}{6}$ of a grain with the same unvarying effect; and I can safely second Mr. Mellor's remarks, and re-

commend it to the profession as a serviceable and excellent remedy.

I remain, sir,
Your obedient servant,
H. S. BELCOMBE, M.D.

Minster-Yard,
March 18, 1837.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALFERNET.

1. *A Translation of the Pharmacopœia of the Royal College of Physicians of London, 1836; with Notes and Illustrations.* By RICHARD PHILLIPS, F.R.S.L. & E., &c. (By permission.) Highley.
2. *The Pharmacopœia Collegii Regalis Medicorum Londinensis. Translated, with a Commentary, Chemical, Pharmaceutical, and Medicinal,* by D. SPILLAN, M.D., &c.

THE above are the only translations of the new London Pharmacopœia which have as yet made their appearance, though a third has been most pompously announced, and subscriptions for it solicited.

Mr. Phillips's work deserves on all hands to be first noticed. Dr. Spillan very properly observes, that "no one is better qualified than Mr. Phillips to give a translation of, and commentary on, the Pharmacopœia. His well-earned reputation as a scientific chemist, and the fact of his having been appointed by the College a member of the Committee for its arrangement, peculiarly entitle him to the right of explaining the *rationale* of processes in conducting which he himself acted so considerable a part." When, however, we compare the present position of Mr. Phillips, with respect to the College, with that he formerly occupied (a few years back), we cannot help exclaiming—

"Tempora mutantur et nos mutamur in illis."

The principal value of Mr. Phillips's book consists in the notes and illustrations. They are concise, and for the most part very clear, accurate, and valuable. We cannot, however, compliment him on his diagrams explanatory

of the theory of the processes; they are bad and confused. It would have been much better had he constructed them on the plan followed (we believe not invented) by Dr. Boswell Reid. Meissner's diagrams (in his *Handbuch d. Allgemein und techn. Chemie*) are much superior to those used by Mr. Phillips.

There is an omission in these diagrams which we much regret; we mean the number of the reacting equivalents. By the way, why has Mr. Phillips omitted to give diagrams illustrative of the chemical changes which occur in the manufacture of hydrocyanic acid, oxysulphuret of antimony, &c.? They could be readily formed, and ought not to be left out.

We congratulate Mr. Phillips on the alteration of his opinion with respect to the existence of the oil of wine. In the translation of the last edition of the Pharmacopœia, he told us he was unable either to manufacture or purchase this compound, though to our certain knowledge it has been manufactured and sold at Apothecaries' Hall for many years (we believe for at least half a century). And here we may remark, that we think Mr. Hennell has behaved very generously in furnishing what Mr. Phillips acknowledges to be "highly useful information," after the (as we believe, unfair) charges brought by Mr. Phillips against the chemical operators at the Hall.

We strongly advise Mr. Phillips to have the medical information contained in his translation carefully revised and corrected for the next edition: we can assure him there are numerous errors in it. For example, the account of the effects of Aconitina is very incorrect. Mr. Phillips tells us that its "taste is at first bitter, and afterwards acrid; but this is not permanent, and appears to be derived from another principle (anemonia), from which it may be separated by repeated solution in, and precipitation from, acids." Now we beg leave to tell the author, that one of the essential characters of aconitina is intense and permanent acidity, and we challenge him to produce us aconitina by the process in the Pharmacopœia, devoid of this property.

Mr. Phillips is equally in error when he says, that "applied to the eye, it occasions a temporary dilatation of the pupil;" aconitina causes contraction of

the pupil, even in old amaurotic cases. For further information on this point, we would refer to Dr. Turnbull's late publication.

Another error, and one of a gross kind, occurs under the head of iodide of lead. This substance, Mr. Phillips says, is "used only in the form of ointment"!! We presume every member of the profession must have either seen or heard of the internal employment of iodide of lead; and therefore we can only attribute this error to Mr. Phillips not having consulted any physician or surgeon on the subject: we advise him to peruse Dr. O'Shaughnessy's translation of Lugol's Essays, pp. 205, *et seq.* 1831, before his next edition appears.

Again, there is surely a mistake in the dose of the *compound solution of iodide of potassium*. Mr. Phillips says the dose is "from $\mathfrak{m}\nu$. to $\mathfrak{m}\chi$." Now ten minims of this solution contain only $\frac{1}{12}$ of a grain of iodine, and $\frac{1}{24}$ of a grain of iodide of potassium.

We could refer to several other analogous errors, but we have said enough to convince the author of the necessity of revising this part of his work.

On a former occasion*, we took notice of Mr. Phillips's statement with respect to the nature of Prussian blue; and we may here add, that, in a work like the present, we conceive Mr. Phillips ought either to explain the composition of the different substances, and the changes in the various processes, according to the present received and approved doctrines of chemistry,—or at any rate, to give his reasons for taking different views of them. We wish he had followed either of these plans with respect to Prussian blue. In his translation there appears to us to be a singular lack of information on the composition of the double salts,—a want of those comprehensive views so necessary to the proper understanding of the nature of these compounds.

Notwithstanding the preceding strictures, Mr. Phillips' translation is certainly a useful and valuable work; and we strongly recommend it both to practitioners and pupils.

Dr. Spillan's production is neatly and shewily got up; but we regret we cannot speak favourably of its contents.

* MEDICAL GAZETTE, p. 791, present volume.

The translation is frequently bad or even erroneous: thus the word *rhizoma* is translated *root*; "concretum in propriis capitis cellis repertum" is rendered "a concrete substance found in cells of the head" (the important word *propriis* not being translated). Short sentences are often left out: thus, under *Lacmus*, "*thallus præparatus*" is omitted, and the sentence "*quantum fieri potest*," at page 25 of the *Pharmacopœia*, is not translated.

These, be it remembered, are only a few of the errors we have observed on examining about half a dozen pages selected at random.

The *notes* abound in the grossest errors. The author is evidently ignorant of chemistry, and totally unfit, therefore, to criticise the processes, or to offer explanations thereof. There is not a single statement on chemical subjects that can be relied on. The account of the effects and uses of the substances is not better than that contained in Mr. Phillips' translation, and oftentimes not so good. Mr. Phillips, besides, almost invariably gives the doses of the preparation, whereas, in a large number of instances, Dr. Spillan has omitted to do so.

We are sorry to have had occasion to speak thus severely of his translation, for we can assure Dr. Spillan we were *a priori* disposed to report favourably of it.

Medicinische Phænomenologie; ein Handwörterbuch für die ärztliche Praxis. (Medical Phenomenology; or a Dictionary of the Practice of Medicine). Von ROBERT KÜTTNER, M.D. 2 Bände. Leipzig; Schloss.

THE title of this dictionary is sufficiently explicit: the work embraces all the signs and tokens of disease, arranged in encyclopædia fashion; presenting, in short, a kind of medical *conversations-lexicon*. In an art so conjectural as ours, the advantage of having a good book of ready reference, on the phenomena which present themselves, often very unexpectedly, cannot fail to be appreciated by practitioners; particularly by those who have not yet acquired an extensive experience. The *Phænomenologie* differs from an ordinary medical dictionary, inasmuch as it gives, in an alphabetical arrange-

ment, all the symptoms of disease, as well as diseases themselves manifested by their symptoms. Thus we find the face considered in reference to its varied expressions indicative of disease; the appearances of the eyes, the phenomena of the pulse, &c.; and all treated in a compressed aphoristic style, exhibiting at once brevity and clearness. There is an acuteness, we would also say a profundity, in some of the prognoses attached to certain symptoms, which cannot fail to strike the reader. We have been tempted to wish, in perusing some parts of the work, that the author had given references to his sources; but on reflection, such a proceeding must have swelled the two volumes to a very inconvenient size.

Pathologie und Therapie der psychischen Krankheiten. (Pathology and Therapeutics of Mental Diseases.) Von FRIEDRICH BIRD, M.D. Berlin.

THE author of this work has been distinguished for several years back, by the number of his contributions to medico-psychological science, but has here concentrated himself in the production of a book purely practical. We must content ourselves with recommending it in strong terms, as our limits at present preclude an analysis. In the dearth of good books on the treatment of mental disorders in our own language, we should be disposed to wish that this of Dr. Bird's were translated by some experienced hand.

Medicinischer Almanach für das Jahr 1837. (Medical Almanack for 1837.) Von DR. J. J. SACHS. Berlin. Schloss.

So large a mass of useful and interesting information, collected together in a Medical Almanack, we have never before seen. Biography, the state of the Universities, original articles on subjects of general importance, and abstracts of the best articles which have appeared in the German periodicals during the last year, form a miscellany of much attraction; and the spirit of the whole is excellent: no dogmatic or impertinent obtrusion of the editor's opinions are any where observable.

MEDICAL GAZETTE.

Saturday, March 25, 1837.

“Licet omnibus, licet etiam mihi, dignitatem
Artis Medicæ tueri; potestas modo veniendi in
 publicum sit, dicendi periculum non recuso.”

CICERO.

THE

WARBURTONIAN UNIVERSITY.

SOME curious reader may ask which University we mean by the title prefixed?—Whether the University College, which so long affected the superior appellation, and in which Mr. Warburton has from the first been a prime mover?—or can it possibly be the new establishment recently chartered for giving degrees, and at the Council board of which the member for Bridport has also secured for himself a seat? We mean precisely the latter.

But it should be some very simple reader who would ask the question,—some “Shallow,” who would be put to his wits’ ends by the interrogatory—

“Under which king, Bezonian? speak, or die!”

Every one knows that there are two potentates connected with the newly-chartered University—one the noble Earl, “our beloved cousin,” who is duly and regularly placed at the head of the institution; the other a personage who is well disposed, and nothing loath, to take upon him the whole virtual direction. Now who does not see that, at least in the arrangements of the medical department, the unobtrusive authority of Lord Burlington must fall prostrate before the renowned attainments of the great patron and guardian of the medical profession, the illustrious chairman of the Committee of Medical Education? It is in this way that merit of a peculiar kind always works out for itself a suitable seat in which to conduct its operations.

“Coming events,” they say, “oast their shadows before.” We lay no claim to second sight, or to be seers into futurity: we only watch the “shadows,” and it is thus that in our mind’s eye we have traced out, without much difficulty, what is yet to be,—unless the predetermined object of certain parties, which looks very like a plot or an intrigue, be defeated.

We last week alluded to a scheme which is on foot to institute an office—that of Registrar—requisite, doubtless, to a certain extent, but one should think not essentially demanding much personal service in the present instance,—certainly not at the outset of the speculation. Well, what thinks the reader is the modest endowment sought to be fixed upon this office, in these times of economy and retrenchment, by a certain member or members of the Council? Why, the little round sum of 700*l.* or 800*l.* a-year (“say 800*l.*”) has been slyly solicited; but, fortunately for the public, not yet awarded. The hint is worth attending to; for if the scale of expenditure be commenced with a little item of this kind, the public had need to look cautiously how their money is voted away in passing the next supplies.

What may be the duties of Registrar in the new establishment, we cannot exactly say; but we dare to conjecture that they cannot be very onerous for some time. The 800*l.* a-year, therefore, appears to us very much to resemble a job.

Candidates, we understand, of very various orders of merit, have offered themselves; among them, a learned physician of the provinces, a *ci-devant employé* of the College in Gower-street, and an official person, whom we should have thought sufficiently provided for already. The latter person is the useful *factotum* to whom we alluded last week, and who is backed by Mr. War-

burton against all comers. Does this render the transaction less like a job?

Such is the auspicious commencement of business in the newly-chartered institution: it exhibits, in a strong light, the earnestness with which certain of its functionaries wish to identify its interests with their own; and in a council, where all were intended to be placed on an equal footing, the anxiety of at least one to rule and govern the rest. Let that one only have his own registrar—an *attaché*, bound in gratitude for some valuable favours already conferred—and the University is virtually in the hands of the wily councillor.

Let it not be supposed that we bear any hostility to the institution abstractedly: we have long advocated the propriety—the expediency—of having in this great metropolis a corporate body, endowed with the power of granting degrees to London students. But in the present instance, as we have on other occasions fully explained, we soon found ourselves obliged to withhold our confidence and approbation: the miscellaneous group of Fellows suddenly appointed, after their chairs had been going a begging for many months, were far from impressing us with respect for the nascent establishment; while the name of one at least of the well-beloved Councillors or Fellows was of itself sufficient to stamp the character of the institution. Add to this what we have observed among the very first acts of the University—their intriguing, or permitting intrigue, in order to create an expensive sinecure, and the pertinacious exertions of one of them to thrust his well-known factotum into the office:—who of fair, candid, and honest principles, must not be disgusted with the whole affair?

To those of the council who wish well to the establishment, and who pre-

fer that it should be regulated on straightforward rather than jesuitical principles, we earnestly recommend a steady consideration of these things. They will soon see the danger likely to arise from the predominance of an intriguing influence amongst them. An exclusive denomination will be fastened on the University: it will be called after the individual who monopolizes the functions of his colleagues, and who, by his pernicious interference, brands the institution with an indelible impression. We warn the steady well-intentioned members of the council—for we know there are some such—to guard against and strenuously resist this influence. Let them, as they value the institution to which they belong, set their faces against jobbing and intrigue, the very imputation of which in the outset were enough to stifle all hope of future respectability.

This week we have just glanced at the job of the registrarship: we have something to say on another occasion, when we have more room, concerning certain other curious proceedings of the Council, and their virtual President. Ostensibly only a few days have been devoted to business at Somerset House; but, from the issue, we suspect that all has not been done above board. A little time, no doubt, will open up the mystery.

ROYAL INSTITUTION.

Friday, March 17, 1837.

New mode of exciting the common Voltaic battery.

MR. FARADAY gave a lecture this evening on Mr. De la Rue's method of exciting the common Voltaic apparatus, by a solution of sulphate of copper, instead of the dilute acid ordinarily employed. The lecturer stated that this salt had been applied to the voltaic apparatus, first by Mr. Daniel, afterwards by Mr. Mullens, and,

subsequently by Mr. De la Rue. The two former gentlemen, however, use a peculiar form of apparatus, and insert animal membrane between the zinc and copper plates, whereas Mr. De la Rue employs the ordinary apparatus, making use of no membrane.

Mr. Faraday then proceeded to perform various experiments, in order to show the power of the battery when charged with the cupreous solution. These consisted of the decomposition of water (in the voltmeter), and the ignition of charcoal, and various metallic leaves. Until the termination of the lecture, he failed, however, in igniting platinum wire. The deflagration of the metallic leaves was, in our opinion, not equal in brilliancy to what is observed when the battery is charged with acid. Indeed the exhibition was altogether not a very successful one, and which Mr. Faraday admitted, but stated that he had not previously tried some of the experiments.

It appears to us, that this new method of exciting the common voltaic apparatus is more curious than useful. It is more expensive, we believe, than the ordinary method: the battery is put in action very slowly—an hour or two, at least, being required to get it into a working state; and, lastly, it is uncertain in its action, as proved by the fact that even in the hands of Mr. Faraday it was not completely successful. Twice, during the lecture, Mr. De la Rue was obliged to put acid into the cells of the troughs, so that the effects shown by Mr. Faraday were not produced by the sulphate merely. Indeed, after the lecture, Mr. De la Rue admitted, that unless the plates were perfectly clean (a condition rarely met with in large batteries), some acid must be employed.

In noticing the theory of the action of the sulphate of copper, Mr. Faraday, in the first place, showed the efficacy of the solution as a conductor of electricity, and then stated that it was at present somewhat uncertain on what the efficacy of the sulphate, as an excitant, depended: whether on its obviating the evolution of hydrogen, or by its putting the zinc in a new condition.

A pretty little piece of apparatus for subjecting points of various substances to the galvanic influence, invented by Mr. De la Rue, was shown. Silver was ignited by it, and produced a beautiful green light; and the colour of the light evolved by the ignition of charcoal points was variously altered by strontian, soda, and boracic acid.

At the conclusion of the lecture, Mr. Faraday very feelingly alluded to the murder of Mr. Davidson, who had been a pupil of his and Mr. Brande's.

SIR BENJAMIN BRODIE'S HUNTERIAN ORATION.

AN oration of this nature can scarcely be considered a fit subject for critical analysis, but we have made a few extracts, with appropriate headings, which we think will be interesting to our readers:—

Dr. W. Hunter's Museum.—If we inquire into the private life of Wm. Hunter, we find that he was never married; that his domestic establishment was on a very limited scale, and that his habits were of the most frugal kind. But let us not suppose that this was in any degree the result of avarice. He had no taste for those luxuries, or for that display, for which wealth is usually exchanged; or, at all events, he had another object in view, which he prized more highly than these: and, in whatever related to this, he was liberal even to extravagance. I need scarcely say that I refer to his museum. I have already had occasion to mention that part of it which related to anatomy. It was collected for the purpose of illustrating his lectures, and its chief value consisted in the preparations illustrative of the changes of the gravid uterus, in those relating to diseased structure, and in the catalogue. The latter is replete with the most interesting pathological information on a great variety of subjects; and I am greatly deceived by my juvenile recollections of it, if I am not justified in asserting that the publication of it, even at the present time, would be of the greatest service to our profession.

But many present remember, as I do, that the anatomical department occupied only the gallery of the building in which the museum was placed. A most valuable and extensive library, and a costly collection of medals and minerals, filled the lower part of it, and served to demonstrate that the collector of these treasures could well estimate the value of other branches of knowledge, as well as those in the pursuit of which he was himself engaged. There was a collection of paintings also, by the first masters, but deposited in other apartments. It is said that the expense of forming the museum did not amount to less than 100,000*l.*, the whole of which was derived from the savings of a laboriously earned professional income.

This museum is now deposited in the University of Glasgow. We cannot grudge the possession of it to that institution which had the honour of forming the young mind of him who has done us so much honour since. But some persons

may be of opinion that, as it would have been more accessible, so it would have been more useful, if placed in this metropolis of the world rather than where it now is. Such seems to have been William Hunter's opinion also. How it happened that he altered his original intentions respecting it, is so well known, that it may seem almost superfluous to say a word on the subject. He pointed out to the government of that day, a vacant piece of ground belonging to the crown lands in the vicinity of Charing-cross, on which, if it were granted to him for that purpose, he offered to erect a suitable building, and establish his museum, at the same time endowing a professorship, and to bequeath the whole to the public. The minister to whom this proposal was made, scarcely condescended even to answer William Hunter's letter!

Cuvier and Hunter. — The study of comparative anatomy (that term being intended to designate the anatomy of animals generally, as contradistinguished from the anatomy of any single species) is of very ancient date. It is one of those many branches of science which occupied the comprehensive mind of Aristotle; and since the revival of the love of knowledge from the torpor of the dark ages, there have been always individuals who pursued it to a greater or less extent. But, up to the middle of the last century, these inquiries were carried on in a vague and desultory manner. A master-mind was wanting, capable of grasping the entire subject; of analysing, combining, and arranging the apparently heterogeneous and discordant materials of which it is composed; and of exhibiting them in their mutual relations, forming one harmonious system, worthy of the Creator of the universe. Those who attribute the glory of having first accomplished these objects to Cuvier, do great injustice to our own countryman. The labours of John Hunter preceded those of the French philosopher. In Cuvier's work on Comparative Anatomy, we find recorded an immense number and variety of facts connected with the structure of all kinds of animals; but we need only to walk into the museum of this College to see the facts themselves, displayed by the hand of John Hunter, or under his immediate superintendence. I was acquainted formerly with a most intelligent Greek, who having received the best education which Greece afforded, passed some years in this country. This gentleman was accustomed to describe one of the advantages which he had derived from his visit to England, in something like the following terms: — "I had acquired in Greece a good deal of the learning which is to be obtained from books; but I now

know how much inferior the study of books is to the study of things." Such is the difference, in one respect, between the lectures of Cuvier and the museum of Hunter.

But that museum is not merely a great collection of anatomical specimens: the distribution and arrangement of them indicate the most philosophical views of physiology. The mind of the student is gradually led from the elementary to the most complicated forms of animal existence. The simple functions of one race of creatures serves to illustrate what would be otherwise incomprehensible in the functions of others. It cannot be doubted, that the arrangement of the Hunterian Museum suggested to Cuvier that which he adopted in his lectures, although he deviated from it in some particulars.

Although between forty and fifty years have elapsed since the death of John Hunter, there is one part of his labours in anatomy and physiology which has only lately become known to the public. He left behind him some manuscript notes, intended to be introductory to the study of the several departments of his museum. These are now being published in the catalogue; and they exhibit, in a remarkable degree, those powers of observation, of tracing resemblances and analogies, and of generalisation, which belong to genius, and lay the foundation of discoveries. It cannot be doubted that an accomplished writer would readily convert these notes into essays, not less interesting and instructive, and certainly containing more original matter, than the introductory chapters which we read with so much delight in Cuvier's lectures.

I trust that, in the comparison which I have now made between Hunter and Cuvier, I shall not be suspected of any want of respect for the last-mentioned of these distinguished philosophers. Such are the riches of Cuvier's reputation, that there can be no inducement to claim for him any part of the wealth of others; and his most zealous admirers cannot reasonably complain, if we concede to John Hunter the superiority as a comparative anatomist and physiologist. In other matters Cuvier stands without a rival. He was deeply versed in natural history, which Hunter cultivated merely as subsidiary to anatomy. By his researches respecting the fossil remains of animals, he became the inventor of an entirely new science; of that science, which the genius of Buckland has made one not only of universal interest, but, I may say, of practical importance, by applying it to the illustration of the great truths of natural theology.

John Hunter's Industry.—The first thing which it occurs to me to notice in the character of John Hunter, is his unrivalled perseverance and industry. His life was one of incessant labour. He slept a little after dinner, and four hours were devoted to sleep after midnight; otherwise he was constantly employed in some one of his pursuits. When my friend Mr. Thomas brought him a letter of introduction on his coming as a student to London, Mr. Hunter appointed him to call upon him at five o'clock on an October morning. Mr. Thomas was punctual to his appointment, and found him already busily engaged dissecting an insect under the light of a lamp. Undoubtedly much of this was to be attributed to his physical construction. He could dispense with a portion of that sleep which is indispensable to others. His animal frame enabled him to make exertions which others were incapable of making. But much was to be attributed also to the operation of a vigorous and energetic mind, triumphing over the weakness of the body. For some years before he died, he had laboured under the symptoms of complicated bodily disease, including those of *angina pectoris*, and his sufferings were often severe and alarming. But this, which would have reduced most others to a state of inaction, made little difference to him. His pursuits were scarcely interrupted by it. When Mr. Thomas visited him at five o'clock in the morning, he was in that state in which any sudden and violent emotion of the mind might have endangered his life.

His Experiments on Vegetables.—When I was formerly giving lectures as Professor of this College, I found in a drawer of the museum what appeared to be some pieces of dried sticks. Mr. Clift said that he did not know what they meant; but he was sure that they meant something, and therefore that he had preserved them. When I examined them, I found that they were the result of some interesting experiments in vegetable physiology. It appeared, from one of them, that he had made the first and most important of the experiments made many years afterwards by Mr. Andrew Knight, proving the descent of the sap through the vessels of the bark. Yet these specimens had no ostensible place in the museum; and they would have been swept away as rubbish but for the care of Mr. Clift.

Character of Home.—There was another distinguished individual, the last of the school of the Hunters, who was joined with Dr. Baillie in instituting this annual commemoration of his relative and preceptor: and whom I feel myself the more called upon to mention, as I was indebted to him for many acts of kindness in the early part of my professional career, and

as I cannot doubt that some circumstances, to which it is painful for me even to allude, and into the consideration of which I certainly do not feel myself called upon to enter, have tended to cast a shade over the merits which he really possessed. I shall endeavour to describe Sir Everard Home, such as he appears to me to have been, when I first became acquainted with him. He was a great practical surgeon. His mind went directly to the leading points of the case before him, disregarding all those minor points by which minds of smaller capacity are perplexed and misled. Hence his views of disease were clear, and such as were easily communicated to his pupils; and his practice was simple and decided. He never shrunk from difficulties, but, on the contrary, seemed to have a pleasure in meeting with them, and overcoming them: and I am satisfied that to this one of his qualities many of his patients were indebted for their lives. Much valuable information is to be found in his surgical works, and his observations on ulcers, and those on the diseases of the prostate gland, may be perused with advantage by the best educated surgeons of modern times. He possessed the art of employing every instant of his time; and could, with perfect ease, transfer his attention at once from one subject to another quite different from it. Hence it was that he was enabled, although engaged in a large private practice, to pursue the study of comparative anatomy to a considerable extent. His earlier papers on this subject, communicated to the Royal Society, are of great and acknowledged value. But, unfortunately for his reputation, his ambition rather increased than diminished, while his mental powers were gradually declining under the influence of an indifferent state of health, and increasing years. In his latter days he had an overweening anxiety to appear before the world as a discoverer; and his friends in the council of the Royal Society too readily inserted whatever he offered to them in the Society's Transactions; and the result has been, that many of his later communications are of such a nature that his best friends must now regret that they were ever published.

Character of Blizard.—Sir Wm. Blizard retained his faculties but little impaired, even when he had entered his ninety-third year; and this and other circumstances combined to render him an object of interest with us all. He stood among us like the remnant of a former age, and we are always to bear this in mind, when we form our estimate of his professional character.

It is not to be supposed that, at his advanced period of life, he could have kept

himself on a level with the increasing knowledge of the day; and it is but justice that we should compare him, not with those among whom he died, but with those who were his competitors in the meridian of his life. We find that he then occupied a considerable station in society, and he retained his reputation for so long a time, that we cannot but suppose that it rested on a substantial basis. He possessed extraordinary zeal and energy; unbounded activity in a great degree supplied the place of steady industry, and these qualities mainly contributed to his elevation. Of a sanguine and enthusiastic turn of mind, he carried something like the spirit of chivalry into the sober pursuits of his profession. To this College, especially, he had a kind of romantic attachment, and I have no doubt that he believed that all the world joined with him in his admiration of it:—

Nil oriturum alias, nil ortum tale fatentes.

It was curious and pleasing to see so much of the simplicity of a boy remaining in the old man, after more than seventy years of incessant occupation in this busy world!

Sir William Blizard was distinguished for a remarkable degree both of physical and of moral intrepidity. Of the former, many examples were well-known to his acquaintance; and the whole tenor of his life was a demonstration of the latter. Where he had made up his mind that a certain line of conduct was the proper one for him to pursue, (and in this it was with him as it is with most of us, that his judgment was sometimes right and sometimes wrong), nothing could turn him from his purpose. His own private interests never entered into his calculations. Indeed, with respect to these he was careless in an almost extreme degree. Many years ago he lost nearly the whole of the savings derived from his professional labours, by coming forward to assist a near relation who was in embarrassed circumstances; and he never redeemed his fortune to any considerable extent, although he certainly might have done so, if that had been his object, and he had no habits of personal expense to prevent him.

A College Examination.—At a meeting of the Court of Examiners, not long before he died, he (Sir William Blizard) began his examination of a candidate in the following manner:—"Be so good, sir, as to explain to me the difference between schindylesis, synarthrosis, diarthrosis, and ginglymus?" The young man hesitated, evidently not comprehending the question, when some one suggested to Sir William that these terms were not much in use among the modern teachers of anatomy. He shook his head, lamenting, as much in

earnest as in joke, the degeneracy of the age.

Appoinment of a Hunterian Professor.—The lectures illustrative of the museum have hitherto been consigned to different members of the College, none of whom have found it convenient to retain the office of professor for more than three or four years; and who, being engaged in other laborious duties, were seldom able to do full justice to the task which they had undertaken. Those lectures will now be delivered by the junior conservator, Mr. Owen, whose zeal and talents are known to you all; and who, devoting himself entirely to anatomy and physiology, will prove, as I venture to predict, a more efficient professor than any of us, who have preceded him. Thus there will be established, by means of this great museum and the lectures, a school of what may be called the "science of life," such as has never existed in this metropolis before, and we may reasonably conclude that this will ultimately be productive of great practical results. The wards of the hospital and the dissecting-room will enable the diligent student to obtain an adequate knowledge of what has been already done in surgery, and to become a good practical surgeon; but those who would earn for themselves pre-eminence, by adding to our stores of knowledge and improving the science of their profession, must carry their views further, contemplating the phenomena and laws of life generally; not as they are exhibited in our own species only, but as they exist in the whole animal creation. If John Hunter had confined himself to a knowledge of human anatomy, however minute, and to mere clinical studies, his treatise on the Blood and Inflammation could never have existed. I need go no further than this. This indisputable fact is in itself sufficient to convict those of ignorance and error, who hold that medicine and surgery are but empirical arts, and that physiological researches, and scientific views of disease, are of little importance to the practical physician and surgeon.

FATAL ENTERITIS PRODUCED BY LUMBRICI.

DOCTOR PETRENZ, of Schandau, has published the following case in *Clarus and Radius's Journal*:—

A girl, aged nine years, of feeble habit, and pale, cachectic appearance, and, from the poverty of her parents, accustomed to poor and insufficient diet, was attacked with pains in the abdomen, and periodic thirst. After these symptoms had lasted for some time, she was seized with vomiting, and threw up a lumbricus. She then

got rigors, followed by heat of skin, pain in the bowels, and violent thirst. When seen by Dr. Petrenz, her face was covered with a cold perspiration; her hands cold and blue; feet moderately warm; belly distended and painful; bowels confined for two days; urine suppressed; tongue moist; great bodily weakness; but no affection of the sensorium. The usual remedies were promptly applied, but three hours afterwards the whole body became cold, the respiration laboured, and the patient, having discharged a lumbricus, with a large quantity of blood, per anum, suddenly expired.

On opening the abdomen, the intestines were found in a state of gangrene, particularly the cæcum, colon, and rectum. The right and left flexures of the colon were distended with a mass of lumbrici; in the former, Dr. Petrenz counted fifty worms, in the latter, nearly as many. The remaining portion of the large intestine contained also a considerable quantity. The number found in the whole intestinal tube was computed to be about 200. No trace of mucus, or any of the usual contents of the intestines, could be discovered. The rest of the abdominal organs were in the normal state. There were no worms in the stomach. There was no perforation in any part of the digestive tube, nor were there any worms found in the cavity of the peritoneum.—*Dublin Journal.*

AWFUL MISTAKE IN MIDWIFERY PRACTICE.

MALIGNANT soft tumors, whether of the uterus or ovarium, when they present themselves in the vagina at an advanced period of utero-gestation, give to the less experienced medical attendant the idea of a *placenta prævia*, and many have acted under this erroneous impression. One of the most extraordinary cases I ever was summoned to, proved to be of this description; the operator passed his hand through the soft tumor in the vagina, and missing the uterus, entered the abdominal cavity, seized and ruptured the gall-bladder, and actually delivered numerous biliary calculi *per vaginam*! I communicated this case some time since to Professor Naegle, for publication in a foreign journal. I was not summoned until after the decease of the patient; and in the presence of three practitioners I opened the body. Numerous fungoid tumors arose from the right ovarium, and one of them, descending into the pelvis, had presented in the vagina, and being torn, furnished the hæmorrhage; pieces of this soft tumor were removed, and appeared to be the placenta, and some loss of blood continuing,

delivery was determined upon, but no foetus could be found; the hand of the accoucheur had passed through the soft tumor occupying the vagina, into the peritoneal cavity, and the gall-bladder, filled with biliary calculi, had been seized in the search for the foot of the foetus. Dissection verified the occurrences as I have stated them; the uterus and its appendages are in my pathological collection.—*Mr. Crosse's Retrospective Address.*

A GENERAL BILL

OF THE

BURIALS, WITHIN THE CITY OF LONDON, AND BILLS OF MORTALITY,

From Dec. 15, 1835, to Dec. 13, 1836.

GENERAL OBSERVATIONS.

The mode of keeping these registers is as follows:—

At *Edmonton*, the warmth of the day is observed by means of a thermometer exposed to the north in the shade, standing about four feet above the surface of the ground; the extreme cold of the night is ascertained by a horizontal self-registering thermometer, in a similar situation. The daily range of the thermometer and barometer is known from observations made at intervals of four hours each, from eight in the morning till the same time in the evening. The weather and direction of the wind are the result of the most frequent observations. The rain is measured every morning at eight o'clock.

At *Cheltenham*, the temperature is ascertained by a horizontal self-registering thermometer, suspended about five feet from the ground, in a north-east aspect; and the observations made at eight o'clock A.M. The pressure of the atmosphere, and the direction of the winds, are registered at eight o'clock A.M., and eight o'clock P.M. The quantity of rain which has fallen is registered at eight o'clock A.M.

CHARLES HENRY ADAMS.

CHELTENHAM.—Kept by Mr. SAMUEL MOSS, Chemist.

MANSLAUGHTER BY MORISON'S PILLS.

ANOTHER of Morison's agents, a man of the name of La Mott, residing at Hull, was tried and convicted lately at the York Spring Assizes, for having administered to a Mrs. Russell a quantity of Morison's pills, and thereby caused her death. This case exhibited as gross quackery as any of its predecessors. Mrs. Russell had been a stout healthy woman, but suffered occasionally from constipation. For two years before her death she was in the habit of taking Morison's pills, for what she called "windy dropsy," and a pain in the kidneys. On the 9th August last she complained of illness, and the prisoner was applied to. From that moment the pills were perseveringly administered, until the patient sunk under her sufferings. The morbid appearances of irritant poisoning were found in the stomach, and particularly at the pyloric orifice. The mucous membrane of the intestines was softened throughout. For the defence witnesses were called as usual, who said they had taken the pills with benefit. The prisoner was found *Guilty*, and sentenced to nine months' imprisonment.

REMUNERATION FOR MEDICAL ATTENDANCE ON PAUPERS.

It becomes a matter for consideration, whether the power of appraising these professional services should not be left to some impartial tribunal, which might decide according to any peculiar circumstances appearing to dictate a variation either in the rate or in the form of such remuneration.

If this were considered desirable, the valuation might be entrusted to a Board, consisting of three medical men; two of whom should be appointed by the government, the third by the medical faculty: or if, instead of a Medical Board acting *per se*, two or three medical Commissioners or Assessors, acting in conjunction with the Poor-Law Commissioners, were preferred, it would be equally necessary that these should, partly at least, be appointed by, and responsible to, the profession. An analogous arrangement exists in the Tithe Commutation Act, where one of the Tithe Commissioners is appointed by the Archbishop of Canterbury.

Another question arises on this point,—whether the right of appointing such representatives or agents should be vested in the *heads* of the profession, or in the whole faculty.

The former arrangement would prove the most simple, speedy, and practicable,—the right of appointment being entrusted to the President of the College of Physicians, the President of the College of

Surgeons, and the Master of the Apothecaries' Company, jointly;—but supposing it were deemed essential that the whole medical faculty should possess the right of appointment, the following would be the readiest mode of effecting it:—

Every legally qualified medical practitioner, whether physician, surgeon, or apothecary, to possess the power of *nominating* a candidate, as well as of *voting*.

The nominations and votes to be in writing, and to be forwarded by post to the Secretary of State: the legal qualification of each nominator, and of each voter, to be appended to his name, and his signature to be attested by competent witnesses. The majority of votes to decide the election.—*Appendix to Observations, &c.*

 Rain fallen, .025 of an inch.

NOTICES.

A correspondent requests us to inquire of Mr. HUNT, of Dartmouth, who contributed the interesting case of "death of the foetus from twisting of the funis round the neck," in last GAZETTE, whether he noticed the state of the integuments of the neck, as to their being ecchymosed or not? Also, whether he examined the condition of the subcutaneous parts? Information on these points would certainly render the case, in a medico-legal point of view, far more valuable than it can possibly be in its present shape.

"CHIRURGUS RUSTICUS" in our next.

INDEX TO VOL. XIX.

(VOL. I. FOR THE SESSION 1836-7.)

A.

- Aberdeen**, Dr. Macrobin's report for the last year of the Lunatic Asylum at, 336.
- Abscess**, extensive encysted hepatic, Dr. Allnatt on a case of, 699.
- Acid**, iodic, Mr. L. Thompson on a new mode of preparation, 183; case of poisoning with, 349.
- Ad captandum surgery**, 829.
- Affections**, neuralgic, Dr. Griffin on the means by which they may be distinguished from inflammatory, 73.
- cerebral, Dr. Grantham on, arising from deficiency of cranium, 495.
- Age**, the subject of, medico-legally considered, by Dr. Cummin, 65.
- Alcock**, Dr. on the determination of the question, which are the nerves of taste, 295; his reply to Mr. Noble's opinions on this subject, 535.
- Aldis**, Dr. C. J. B. on Baron Sloet's method of treating epilepsy, 142.
- Aldred**, Mr. on the inefficacy of the recent act for remunerating medical witnesses, 376.
- Allan**, Mr. on a case of obstructed ureter, with ulceration of the kidney and abscess, 888.
- Allnatt**, Mr. account by, of a case of extensive encysted hepatic abscess, with hydatids, 699; on a case of abscess of the liver, 818.
- Almanack**, British medical, reviewed, 339; the Stationers' Company's, ib.
- Almonds**, bitter, Mr. Everitt's analysis of, 718.
- Aloes**, Dr. Greenhow on the use and abuse of, 269.
- Anatomy**, surgical, notice of some wax models of, recently imported, 32.
- order with respect to the lectures on, in the University of Dublin, 384.
- Anatomy act**, operation of the, in Dublin, 717.
- Aneurism**, case of, of the thoracic duct, 63.
- popliteal, Mr. Busk on a case of, rapidly and perfectly cured, 185.
- Annales d'hygiène publique et de médecine legale**, review of, 418.
- Antimony**, tartarized, Dr. Kemp on the employment of, in inflammation of the mucous membrane of the lungs, 300.
- Aorta**, Mr. Bullock on an anomalous distribution of the branches of the, and an unusual course of the right subclavian artery, 702.
- Apologist**, an homœopathic, 90.
- Apothecaries' hall**, observations on the late affray at, 146, 480; remarks, by Scrutator, on the examination and conduct of the examiners, 558; list of gentlemen who have received certificates, 64, 128, 160, 208, 256, 288, 352, 383, 432, 560, 592, 640, 672, 720, 752, 880, 912, 944, 976.
- Apothecaries**, society of, and the new university, 639; adjudication of the annual prizes given by the, with a list of the prize questions, 277; correction of a statement respecting the examination, 320.

General practitioners, proceedings at the dinner of the, 150.

German works recently published, review of, 239, 371, 583, 706, 966.

Girdwood's, Mr. report of the medico-legal examination of the trunk of a human body, which was lately found in the Edgeware Road, under mysterious circumstances, 551 ; of the head, with remarks, 587 ; on the lower extremities, 748.

Glanders and button farcy, Dr. Graves on, in the human subject, 939.

Globule, the organic, Dr. Hake on, 574.

Gout, Dr. Seymour on the various forms of, 311.

Gout and rheumatism, Dr. Seymour on, 327.

Grant, Dr. on the glandular system in the various classes of animals, 749.

Grantham's, Dr. case illustrative of the ill effects of the indiscriminate employment of the ergot of rye, 141 ; on certain cerebral affections arising from deficiency of cranium, 495.

Graves, Dr. clinical lectures by, delivered at the Meath Hospital, and County of Dublin Infirmary:—on the connexion of diseases of the different organs, 149 ;

arthritis, jaundice, and urticaria, *ib.* ; periostitis from mercury, and hypertrophy of the liver, *ib.* ; hypertrophy of liver from scrofula, 450 ; scarlatina, 452 ; importance of noticing these facts, *ib.* ; connexion between disease of the liver and disease of the heart, 521 ; chronic hepatitis, from this source, curable in young persons, *ib.* ; enlargement of the spleen, and superficial ulceration of the legs, 522 ; noticed by Aretæus, 523 ; symptomatology of the ancients, *ib.* ; erysipelas and gangrene sometimes of a pseudo-inflammatory character, requiring stimulant treatment, *ib.* ; remarkable case in illustration, 524 ; epidemic erysipelas as it prevailed lately, 568 ; peculiarity of erysipelas spreading symmetrically, 569 ; maculated fever, and typhus without maculæ, 570 ; treatment of fever—improved method, 571 ; choice of proper assistants—ventilation, 572 ; necessity of attending to diet and nourishment, 573 ; treatment of fever, 665 ; necessity of employing a good nurse, *ib.* ; discrimination requisite in the choice of food, 666 ; drinks to be preferred, 667 ; on the treatment of typhus fever, 727 ; tympanites from want of food or too much purging, 728 ; causes of thirst in fever, *ib.* ; blisters—their action on the capillaries, 729 ; effects of blisters in approaching cerebral symptoms, 730 ; signs of approaching cerebral disease, *ib.* ; state of the pupil during sleep, 732 ; tartar emetic ointment effective in some desperate cases, *ib.* ; management of delirious fever patients, 808 ; advantages of tartar emetic in form of enema, 809 ; subsultus tendinum from disturbance of the nervous extremities, independently of the brain or spinal cord, 810 ; vomiting and purging at commencement of fever indicative of cerebral affection, *ib.* ; scrofulous inflammation of the brain, 811 ; scarlatina without eruption, followed notwithstanding by desquamation, 842 ; thoughts on the nature of desquamation, *ib.* ; latent scarlatina, followed by anasarca, *ib.* ; general proposition respecting the symptoms of animal poisons, 843 ; morbid appearances after delirium in fever, *ib.* ; treatment in anticipation of cerebral symptoms, 845 ; great advantage of blisters judiciously employed, *ib.* ; notice of the old mode of blistering, 847 ; glanders and button farcy in the human subject, 939 ; remark on the variety of skin diseases produced by the introduction of an animal poison into the system, 941 ; furuncular inflammation, or carbuncle, generated by animal poison, 943 ; remarks on phlegmasia dolens—phlegmasia dolens of the eye, *ib.*

Greenhow, Dr. on the use and abuse of aloes, 269.

Greenhow, Dr. on the diseases of North Shields and the surrounding district, 623.
Green, Dr. Jonathan, on a case of lepra and psoriasis treated with sulphur fumigations, 890.

Griffin, Mr. account by, of a case in which living earwigs were found in the alimentary canal, 48.

———'s, Dr. medical problems:—how are neuralgic affections to be distinguished from inflammatory, 73; how symptomatic from idiopathic intermittent, 104, 138.

Gulliver, Mr. on necrosis, 250.

H.

Hake, Dr. on the physiology of salivation, 302; on the virtues of hydriodate of potass, as a remedial agent in disease, 497; on the organic globule, 574.

Halford, Sir Henry, on the effects of cold on the human frame, 902.

Hall's, Dr. Marshall, reflex action of the spinal marrow, 828.

Hancock, Dr. on the Corrowatti, 718.

Hargrave, Dr. of Dublin, note from, 640.

Harrison, Dr. Edwin, propositions by, for the ascertainment of the physical signs indicative of diseases of the chest, 369; on signs observed by auscultation, with some remarks on pectoriloquy, 457; on the height of the diaphragm, 543; on the mode and the amount of clinical and other medical instruction at Paris, 703; on certain errors of Laennec and others respecting the regions of the chest, 776; on certain phrases and expressions in Laennec's celebrated work, 893.

Hassall, Mr. on the operation of the Anatomy Act in Dublin, 717.

Heart, report of the London Committee of the British Association on the motions and sounds of the, with an account of the experiments, 360; Dr. Watson on the second sound of the, being a contribution to the pathology of that organ, 526.

Hemisphere, left, case of destruction of the, without affecting the intellect, 583.

Hernia, strangulated, Mr. Koehler on the employment of the stomach pump in, 382.

———, strangulated inguinal, Mr. Taynton on a case of, operated on with success, 624.

———, treatment of, 799.

Heygate, Dr. account by, of an extraordinary accumulation of fæces in the lower part of the rectum, 413.

Hibernicus on the present state of the Irish medical charities, 27.

Hill, Mr. on a case of lithotomy, 424; note from, respecting an omission in the report, 469.

Hilles, Mr. on the functions of Meckel's ganglion and the glosso-pharyngeal nerve, 577.

Hird, Mr. account by, of an anomalous distribution of the branches of the aorta, and an unusual course of the right subclavian artery, 702.

Homœopathy, Mr. Forbes Winslow on, 83; remarks on, suggested by some recent discussions at the London Medical Society, 116; Mr. Wakefield on, 190; sketched in its own colours, 241; further illustrations of its nature, 305.

Homœopathist, a reverend, 148.

Hooker's, Sir W. J. *Icones plantarum*, reviewed, 191.

Hope, Dr. on the nature and treatment of rheumatism, 812.

Hospitals, small, advantages of, or certificates *versus* knowledge, 92.

Hufeland, Professor, notice of a portrait of, lately published, 203.

Hughes, Dr. on two cases of pericarditis, with auscultatory diagnosis and remarks, 222.

Hulbert, Mr. on local hysterical affections, 406; on a case of typhus fever, &c., 850.

Hunt, Mr. on a case in which the death of the foetus was occasioned by winding of the umbilical cord round the neck, 933.

———, Mr. T. on the functions of the muscles and nerves of the eye-ball, 20, 191.

Hunter, John, portrait of, 751.

———, works, by Palmer, reviewed, 744, 792, 821.

Hunterian oration, editorial observations on the, 794; extracts from, 972.

Hutchison, Mr. Copland, on the infrequency of calculus among seamen, 424; reply to Dr. James Johnson's remarks, 468; account by, of a case of extra-uterine pregnancy, in which a full-grown foetus was removed by an operation fourteen months after conception, 739.

Hydatids, Dr. Ward on, and their origin, 856.

Hydrocele, Mr. Travers on a new mode of operating for, 737; Mr. Lewis on the treatment of, in reply to Mr. Travers, 788; Mr. Kente on the treatment of, by puncture and absorption, 789; Mr. Caswall on the treatment of, by iodine, 855; treatment of, by puncture, by a Constant Reader, 866.

Hygiène publique, review of Parent-Duchatelet's work on, 304.

Hysteria, Dr. Seymour on, 506.

Hysterical affections, Sir B. C. Brodie's lectures on, 197, 246, 279; Mr. Hulbert on some cases of, 406.

I.

Ichthyosis, Dr. Buchanan on a case of, treated by iodine, 82.

Infanticide, alleged, medical evidence in a case of, 92; Mr. Porter on the medical evidence in another case of, 110; case of, and concealment of the birth, 376; Dr. Cummin on, 721, 753, 801.

Inflammation, remarks on some new-fangled doctrines respecting the treatment of, by Investigator, 202, 636.

————, incipient, Dr. Burke on the use of opium in, 228.

————, Mr. Searle on the opposite modes of practice which prevail in the treatment of, 453; challenge to Investigator, 752.

————, Dr. Hume Weatherhead on, 630.

Influenza, notice of the, and its more prominent symptoms, 586; Mr. Bullock's remarks on, and on the nature and treatment of the present epidemic, 700; Mr. Wakefield's observations on, as it has prevailed in the House of Correction, 705; Dr. Clendinning on, 780, 819; Dr. Macleod on, 784; remarks on, by R. J. P., 786; Mr. Morgan on, 816; treatment of the, Investigator's reply to Mr. Searle, 877.

Ingleby's, Dr. facts and cases in obstetric medicine, reviewed, 270.

Instruction, public, in France, 142; organization of the Parisian hospitals, 144.

Instruction, clinical, at Paris, Dr. Edwin Harrison on the mode and amount of, 703.

Intermittent, symptomatic, Dr. Griffin on the means by which it may be distinguished from idiopathic, 104, 138.

Investigator, remarks by, on Mr. Searle's views respecting the treatment of inflammation, 202, 636.

Iodine, Dr. Buchanan on the therapeutical effects of, given in very large doses, 41, 80.

Irish medical charities, Hibernus on the present state of the, 27.

Iron, Mr. Squire on the bromide and iodide of, 339; Mr. Kemp on its preparation, 412.

J.

Jardin des Plantes, great extent of the, and value of the specimens, 150.

Jeffreys, Mr. on the construction and use of the respirator, reviewed, 581.

Johnson, Dr. James, on the prevalence of calculous disorders among seamen, in reply to Mr. Copland Hutchison, 552.

Joints, scrofulous affections of the, Dr. Buchanan on the employment of iodine in cases of, 44.

K.

Keal, Mr. account by, of a case of supposed rupture of the inner coats of the bladder, without injury to the investing peritoneum, 621.

Keate, Mr. on the treatment of hydrocele by puncture and absorption, 789.

Kemp, Mr. on the employment of tartarized antimony in inflammation of the mucous membrane of the lungs, 300; on the preparation of bromide of iron, 412.

Key, Mr. Aston, on the nature and treatment of ganglion, 380.

Kidgell, Mr. account by, of a case of dislocation of the elbow-joint, 112.

Kiernan, Mr. on the minute anatomy of the liver, 169.

Kingston, Dr. abstract of a paper by, on the pathology of pulmonary tubercle, 379.

Knee-joint, Mr. Samuel on a case of lateral dislocation of the, 52.

Knighton, Sir William, biographical notices of, 115, 288.

Koehler, Mr. on the employment of the stomach-pump in strangulated hernia, 382.

L.

Labour, premature, Dr. Ashwell on the induction of, in pregnancy complicated with tumor, 398.

Labour, Dr. Lilburn on a successful case of, where the pelvis was greatly deformed and contracted, 933.

Lecturers, pluralist, at the North London Hospital, 124.

Lee, Dr. Edwin, on the watering places of the continent, reviewed, 273; *coup d'œil sur les hôpitaux de Londres*, reviewed, 371.

Leg, amputation of the, by Sir Benjamin Brodie, 908.

Legislation, prospects of, for the profession, 935.

Lens, dislocated, Mr. Middlemore on the operative proceedings required for the removal of the, 236.

Lepra and psoriasis, Dr. Buchanan on the treatment of, by iodine, 82; Dr. Green on a case of, treated with sulphur fumigations, 890.

Lewis, Mr. on the treatment of hydrocele, in reply to Mr. Travers, 788.

Ley, Dr. Hugh, notice of the death of, 752.

Life, Dr. Philip on the powers of, 921, 952.

Light, Mr. Woodward on the polarization of, 910.

Lilburn, Dr. on French midwifery practice, 859; on a case of successful labour, where the pelvis was greatly deformed and contracted, 933.

- Lithotomy, Mr. Hill on a case of, 424, 469 ; operation for, by Sir Benjamin Brodie, 908 ; by Mr. Hawkins, 909.
- Lithotripsy, as practised by the late Philip Fernandez, Esq., 108.
- Liver, concise and popular view of the minute anatomy of the, as described by Mr. Kiernan, 169 ; Mr. Allnatt on a case of abscess of the, 818.
- Liverpool Northern Hospital, Mr. Banner's report of the surgical cases admitted into the, 49.
- Lloyd, Mr. E. A. on the treatment of vascular nævi materni, 13.
- Lonsdale, Mr. on the functions of the muscles and nerves of the eye-ball, 400.
- Lupus, Mr. Ure on the nature and treatment of, 328.

M.

- Macleod's, Dr. third report of cases treated at St. George's Hospital, with rough notes from his case-book, 691.
- Maclure, Mr. on infanticide by poisoning, 880.
- Macnish, the late Dr., decease of, 672.
- Macrobin's, Dr. medical report, for the last year, of the Lunatic Asylum of Aberdeen, 336.
- Malibran, Madame, editorial observations on the mystery concerning the decease of, 195.
- Marylebone Self-supporting Dispensary, Dr. Copland's resignation, 638.
- Materia medica, or pharmacology, and general therapeutics, Mr. Pereira's lectures on:—*Strychnos nux vomica*, 440 ; historical account of the substance, ib. ; physiological effects on vegetables and animals, 442 ; effects on man—three degrees, ib. ; post-mortem appearances, 444 ; *modus operandi* of *nux vomica*, ib. ; uses in various diseases, 445 ; modes of exhibition, 447 ; tests for it as a poison, ib. ; on strychnia, its history, ib. ; theory of its preparation, 489 ; tests of strychnia, and its salts, 490 ; physiological effects on man and animals, 491 ; on brucia, its history, ib. ; properties and physiological effects, ib. ; uses and mode of administration, ib. ; *strychnos ignatia*, its history, 492 ; false *Angustura bark*—tests and uses, ib. ; *Upas* poison, 493 ; account of its physiological effects, 494 ; snake-wood and Tanghin poison, ib. ; on rhubarb—*rheum polygonaceæ*, 600 ; history of rhubarb—botany, ib. ; characters of the genus *rheum*, 601 ; physical properties and varieties, 603 ; chemistry and physiology, 606 ; on *rumex acetosa*, and *polygonum bistorta*, 608 ; on the umbelliferæ or apiacæ, 680 ; *anethum graveolens*, or dill, 681 ; *pimpinella anisum*, or anise, 682 ; characters, effects, and uses, ib. ; *carum carui*, or caraway, 683 ; properties and uses, ib. ; *fœniculum—asafoetida*, 685 ; characters and properties of *asafoetida*, ib. ; physiological effects and uses, 687 ; *galbanum*, *sagapœnum*, *ammoniacum*, 688 ; *opoponax chironium*, its effects, 690 ; on *conium maculatum*, its history, 763 ; botanical and chemical characters, 764 ; composition and properties, 765 ; salts of conia, how tested and recognized, ib. ; effects on animals, ib. ; physiological effects—on man, 767 ; uses in various diseases, ib. ; tabular view of diseases treated with hemlock, 769 ; *menispermaceæ*—*cocculus palmatus*, 770 ; botanical and physical properties, 771 ; active principle of *cocculus palmatus*, or *calumba*, 772 ; physiological effects and uses, 773 ; *menispermaceæ* continued, 835 ; *cocculus suberosus*, history, ib. ; *cissampelos pareira*, history, ib. ; *aurantiaceæ*—*feronia elephantum*, 836 ; citrus, ib. ; *leguminosæ*, or *fabacæ*, 945 ; botanical characters, ib. ; division, ib. ; sub-order, *papilionaceæ*—*spartium junceum*, its history, 946 ; botanical characters, ib. ; physiological effects, ib. ; uses, ib. ; administration, ib. — *cytiscus scoparius*, its history, 947 ; botanical history, ib. ; officinal, ib. ; chemical properties, ib. ; physiological effects and uses, ib. ; administration, ib. ; *glycyrrhiza glabra*, its history and botanical characters, ib. ; extract of liquorice, 948 ; composition, ib. ; physiological effects and uses, ib. ; *tephrosia apollinea*, ib. ; *astragalus verus*, its history, ib. ; production, 949 ; varieties and physical properties, ib. ; chemical composition and properties, ib. ; physiological effects, ib. ; uses, ib. ; *mucuna pruriens*: cowhage, 950 ; *mucuna urens*, ib. ; *butea frondosa*, ib. ; *pterocarpus santalinus*, 951 ; *pterocarpus draco*, ib. ; *pterocarpus cerinaceus*, ib. ; sub-order: *swartzieæ*, ib. ; sub-order: *caesalpinieæ*, ib. ; *ceratonia siliqua*, ib.
- Maund's, Mr. "Botanist," reviewed, 55.
- Medical witnesses' bill, editorial observations on the, 274.
- Medical witnesses' act, Dr. F. H. Ramsbotham on its imperfections and injurious tendency, 554.
- Medicine, legal, trial and inquest connected with, 376.
- Medicine and surgery, statement of the number of publications connected with, in France, during the year 1836, 672.
- Medicines, list of the names of those which are changed in the new pharmacopœia, 478.
- Medico-legal case, the late mysterious, editorial observations on, 584.
- Mellor, Mr. on the efficacy of the *strychnos*

nuxvomica in affections of the digestive organs, 850.
 Meteorological journals, 64, 96, 128, 160, 208, 256, 320, 352, 384, 432, 480, 512, 560, 592, 640, 672, 720, 800, 832, 880, 912, 944, 976.
 Meyer, Dr. the Cæsarean section successfully performed by, 878.
 Middlemore, Mr. on the operative proceedings required for the removal of the dislocated lens, 236.
 Midwifery practice, Mr. Bull's case in—expulsion of the placenta before the birth of the child, 621.
 Midwifery practice, the French, Dr. Lilburn on, 859.
 Mind, unsoundness of, Dr. Cummin on, 881.
 Mines, accidents in, from explosions of fire-damp, 68.
 Molluscum, Dr. Dick on; with two cases of *molluscum non-contagiosum*, 860.
 Monstrosity, hyperencephalous, Dr. Dick on a case of, conjoined with other monstrous formations, 897.
 Montgomery, Dr. on a newly-discovered peculiarity in the structure of the uterine decidua, or decidua vera, 237.
 Morgan, Mr. on the action of the hydriodate of potass, 617; on the character of the prevailing influenza, 816.
 Morison's pills, another verdict of manslaughter against a vender of, 976.
 Mortality, comparative, of the rich and poor, Mr. Rickman on, 778.
 Mossotti, M. on the forces which regulate the internal constitution of bodies, 848.

N.

Nævi materni, vascular, Mr. E. A. Lloyd on the treatment of, 13.
 Necrosis, operation for, by Sir Benjamin Brodie, 910.
 Nobell, M. account by, of a case of destruction of the left hemisphere, without the intellect being affected, 383.
 Noble, Mr. on the question, which are the nerves of taste? 410; on the sense of taste, and the question of its being a special function, 614.
 Noli me tangere, Dr. Buchanan on a case of, treated by large doses of iodine, 80.
 North London Hospital, operation at, in presence of the patron, 195.
 Northern Dispensary, late resignations at the, 277; resolution of the governors of the, 384.
Nux vomica, Mr. Pereira on, 440.

O.

Ogston's, Dr.—statistics of suicide in Aberdeen, 172.

Operations, crowding at, 467.
 Opium, Mr. Caddy on the efficiency of, in typhus fever, 620.
 Orbit, on the nerves of the—note from Mr. Shaw, 352; Mr. Walker on the muscles and nerves of the, particularly with reference to the functions of the retractor oculi, 368.
 Otic ganglion in the dog, Mr. Bennett on the, 47.

P.

Paralysis from lead, Dr. Seymour on a case of, 151.
 ——— Mr. Elderton on locomotion in, 865.
 Paraplegia, Dr. Seymour on a case of, 156.
 Parish Surgeons and Poor-law Unions, observations respecting, suggested by a recent advertisement, 204.
 Parish unions, query for an Old Navy Surgeon, 256.
 Parturition, feigned, Mr. Thomson on a case of, with remarks on the proofs of delivery and infanticide, 231.
 Paupers, observations on the present condition of medical relief for, with recommendations for an altered and improved system, 874.
 Penis, sloughing sores of the, account by Dr. Buchanan of four cases of, treated by large doses of iodine, 43.
 Penruddock, Mr. report of the trial of, for the assault on the Examiners at Apothecaries' Hall, 715.
 Percussion, Dr. C. J. B. Williams on the theory and practice of, as a mode of diagnosis, 609.
 Pereira's, Mr. lectures on materia medica or general therapeutics—see "*Materia Medica*, Mr. Pereira's lectures on."
 Pericarditis, Dr. Hughes on two cases of, with auscultatory diagnosis and remarks, 222; Dr. Seymour on a case of, supervening on rheumatism, 397.
 Pharmacopœia, the new, correction of an error in it, 500; Mr. Everitt on some of the more prominent novelties, with specimens of the manner in which the old edition has been revised, corrected, and reformed, 528; review of the, 543, 789; Mr. Phillip's observations on Mr. Everitt's remarks on the, 460, 704, 580; Mr. Everitt's reply to Mr. Phillips' remarks on his observations on the, 622; the College of Physicians not empowered to resist the publication of translations, 629; review of Mr. Phillips's translation, 964; of Dr. Spillan's, 965.
 Philip, Dr. A. P. W. on the powers on which the functions of life in the more

- perfect animals depend, and on the manner in which they are associated in the production of their more complicated results, 921, 952.
- Phillips's, Mr. translation of the pharmacopœia, reviewed, 964.
- Phrenonologists, hint to, 256.
- Physic, cheap, at Aylesbury, 62.
- Plumbe's, Mr. practical treatise on diseases of the skin, reviewed, 583.
- Poisoning, suspected, extraordinary verdict of a coroner's jury in a case of, 54.
- Poisoning by fish, Mr. Bullock on a case of, 85.
- with arsenic, Dr. Skillman on a case of, recovered from, after half an ounce had been swallowed, 238.
- with opium and belladonna, Mr. Bullock on three recent cases of, 265.
- case of, with unsound bacon, 378; Dr. Barr's remarks on this case, 455.
- case of, with arsenietted hydrogen gas, 591; from the bite of a viper, cured by sulphate of quinine, 501.
- case of, with castor oil seeds, 944.
- Poor-law club, conduct of its supporters, 95; fresh illustrations of the system, 113; editorial observations on the treatment of a medical officer by the commissioners, 193; trickery practised on the profession, 745; parliamentary inquiry into the working of the, 867, 899; necessity for petitioning against the act, 876; on the propriety of the chartered medical bodies petitioning the legislature, by "A Retired Physician," 907; plan for pauper-relief under the, by "Chirurgus," *ib.*; necessity of endeavouring to avert the evils of the act, by one "Personally Unaffected," 908; commencement of the labours of the parliamentary committee, 912.
- Porter, Mr. remarks by, on the medical evidence in a case of infanticide, 110.
- Potass, hydriodate of, Mr. Smith on its virtues as a remedial agent in disease, 497; remarks on its action, by Mr. Morgan, 617.
- Pregnancy, the subject of, medico-legally considered, by Dr. Cummin, 433, 481.
- extra-uterine, Mr. Hutchison on a case of, in which a full-grown fœtus was removed by an operation fourteen months after conception, 739.
- Pritchard, Mr. account by, of the method of observing the tubulo-fibrous structure of the brain, 414.
- and Dr. Goring's micrographia, reviewed, 546.
- Prostitution, editorial observation on Parent Duchatelet's work on, 372, 418.
- Provincial Association, union of, with the Eastern, 123.
- Puffing, the Lancet's, of the Gower-street hospital, 94.
- Purpura, Dr. Seymour on a case of, 349.
- hæmorrhagica, Dr. Seymour on the pathology of, 393.
- Q.
- Quackery, quarrels of: the new universal medicine, 711.
- R.
- Ramsbotham, Dr. F. H. on the imperfections and injurious tendency of the medical witnesses' act, 554.
